WILEY, P. N., M. D., Norristown, Pa.
WILLIAMS, D. H., M. D., Knoxille, Tenn.
WILSON, H. AUGUSTUS, M. D., Phila., Pa.

YOUNG, W. B., M. D., Bon Air Coal Mines, Tenn.

INDEX.

Abdominal—Growths, 764.
Massage, 423.
Tumors, Supposed to be Ovarian, Goggans, 179.
Wound, Spontaneous Cure of, 434.
Abortion—A Landmark of Gynæcology, Robinson, 608.
Chlorate of Potash in Habitual, 635.
Its Treatment, Webb, 1043.
Missed, 595, 1026.
Treatment of, 570.
Abscesses—In Medulla Oblongata, 309.
In Pneumonia, Artificial Production of, 470.
Acetonæmia, 71.
Aconite, Crystalized Nitrate of, 347.
Acute Cerebral Meningitis Subsequent to Spontaneous Abortion, 850.
Acute Oophoritis as a Sequel of Influenza, 314.
Addison's Diseases, 428.
Adenoid Tumors, Statistics of, 312.
Adenoid Vegetation, Symptoms Produced, 117.
Adler, Lewis H., Jr., 450, 927.
Adulterators, Punished, 319.
Œsophageal Diverticulum, Excision of, 548.
A Few Notable Remedies, Munford, 261.
After Pains, Amyl Nitrate for, 608,
Agnew, D. Hayes, Biography of, 120.
Albumin, Reagent for, 199.
Albuminira—To Psyehoses, Relation of, 472.
As Means of Diagnosis, 676.
Alcohol, Its Value in Diseases (Prize Essays), 597.
Alcoholism—And its Treatment by Strychnine, 791.
Insomnia of, 633.
Treated by Drugs, 702.
Alopecia Areata, 513.
Therapeutic Note on, 108.
Alum in Drinking Water, Delicate Test for, 40.
Amenorrhœa, 596.
American "Crowbar and Skull Case," 936.
American Dermatological Association, 319.
American Electro Therapeutic Association, 479.
Amputated Limbs, Ownership of, 160.
Anal Fissure—or Irritable Ulcer of the Rectum, the Treatment of, Adler, 927.
and Rectal Stricture, 317.
Analin Stains, To Remove from the Skin, 32.
Anæthesia, Local, 633.
Anæsthetics in Obstetrics, The Value of, 909.
Anders, J. M., 361.
An Educational Need, Price, 819.
Animal Diphtheria, To Man, On the Contagion of, 747.
Animal Tissues, Extracts of, 160.
Ankylostomiasis, The Beriberi of Assam, 194.
Antifebrin, Poisoning by, 749
Antinervine (salicylbromanilide), 348.
Antipyrine, 109.
And Euphorine, 80.
Blackening of the Teeth, by, 831, 311.
In Epistaxis, 781.
Anti-Rheumatic, 110.
Antiseptic Mixtures, 155, 347, 633.
Antiseptics And Behavior toward Salivary Digestion, 398.
Antisepsis in Ophthalmology, 354.
Aphthous Stomatis, Etiology of, 478.
Apostolis Methods, 826.
Appendicitis—Pathognomonic Signs of Perforating, 635.
Masked and Complicated by Ovarian Adhesions, McKelway, 602.
Treatment of, 832.
And McBurney, 678, 387, 594.
Aristol and Europhen, Eichler, 53.
Arteries, Torsion of, 517.
Arsenic as a Prophylactic, 1017.
A Source of Danger, 873.
Asphyxia—In New-born Children, 115.
In the New-born, Treatment of, 36.
Ascites in Women, 77.
Association of Hospital Physicians and Surgeons of Philadelphia, 320.
Asthma, 572.
Mechanical Treatment of, 307.
(Hay), Euphorbia Piluligera in, 307.
Its Intra-Nasal Origin and Surgical Treatment, Swain, 287.
Atheromata, Treatment of, 146.
Atraetylis Gummifora, Poisoning by, 73.
Atrophic Rhinitis, The Etiology of, 828.
Atrophine and Morphine, 543.
As a Hemostatic, 629.
As a Hæmostatic, 309.
Aural—Catheter Steam Sterilizer, 549.
Retractor, 146.
Avine Tubercle versus Human Tubercle, 198.
Ayres, Samuel, 18.

Bacillus of Typhoid Fever and Bacillus Coli Monnanis (distraction between,) 356.
Bacteria of Melons, 398.
Bacteriological Notes, 700, 620, 735.
Beef Juice, 867.
Beef and Fish, Digisti Vility of, 871,
Belladonna in First Stage of Labor, 358.
Benedict, A. L., 573.
Bennett, William H., 481,
Beri Beri. Pathogenesis of, 349.
Biliary Duct—Catheterization of, 592. 435.
Biliary Passages, Catheterism of, 433.
Bishop, Louis, tangeres,
Bismuth—Bengoateg, 479
Sub-nitrate in Burns—New Mode of Employment, 829.
Bicyclists. Catarrhal Laryngitis of, 596.
Black, Carl E., 991.
Black Eye, 789.
Bladder, Rupture of, 550.
Blailock, W. R, 679.
Blood—Changes in, 711.
Examinng specemins of, 557.
In Puerperal Seps s, 157.
Specific gravity of, 34.
Clot Treatment of Aneurism and Hæmorrhoids, 987.

Bloom, I. N., 454.
Bone Grafting, successful case, 40.

Dermatol in Surgical Practice, 549.
Dermoid Cyst, Containing a Heart, 714.
Diabetes Mellitus, A New Remedy in, 943.
Diabetes—and functions of female organs, 196.
Aleuronat as a food in, 590.
Mellitus, by Fright, 589.
Diet in, 1020.
Diabetic Urine Testing, 119.
Diaphragmatic Hernia, 332.
Diarrhœa—Infantile, Glyceriting Borax in, 551.
Infantile of Warm Countries, 551.
Use of Strychnine and Digitalis in, 1017.
Diarrhœal Collapse, Subcutaneous Infection of salt in, 425.
Digestive Organs, Method of Examination of, 382.
Digitalis in Aortic Disease, 307.
Digitaline, 469.
Diphtheria, 782, 426.
Convalescent be Isolated, How long should a, 239.
Antipyrine Treatment by, 317, 117,
With Arsenite of Copper, Treatment of, 794
Treatment of, 806, 867.
Silver Nitrate in, 753.
Epidemic caused by Ice, 950.

Permangarate Potassium in the Treatment of, 831,
Ætiology and Bacteriology of, Tower, 181.
Case by Isolated, How long should a, 796.
Infections, Erytherra in, 753.
And Croup, 477.
And Membraneous Pharyngitis, 1019.
Bacillus, Antipyrin Action on, 588.
Invasion of, 117.
Methyl Violet in, 753.
Ingals, 11.
Angina, 348.
Result of, 572.
Tracheotomies for, 1024.
Diphtheretic Paralysis Treatment of, 747.
Disease of the Knee-joint in its Convalescence, Chrystine, 488.
Disinfectant, 625.
Dislocations of Great Toe and Thumb, Irreducible, 473.
Diuretic Drugs, on certain, 783.
Diuretin in Infantile Practice, 30.
Doctor as a Debtor. 518.
Does Influenza Protact from a Subsequent Attack? 278.
Double Hæmorrhagie subdural Cyst, 376.
Dowling, Frances, 642.
Drainage Tubes in Wounds, Objection to, 235.
Drunkenness—As a Virtue, 253.
In Women, Increased, 400.
Dubosine Sulphate, 544.
Dysentery as it Occurrs in Nicarauga, A Clinical Description of, 847.
Dysmenorrhœa and Painful Ovaries, Warren, 499.
Dyspnœa, Caused by Tumor of Neck, 75.
Dystochia from Impaction of the Shoulders, 579.

Ear—Blow Upon—death, 355.

ARISTOL Antiseptic: Cicatrisant.

EUROPHEN Iodoform Substitute: Antisyphilitic.

SULFONAL-BAYER Hypnotic: Sedative.

PHENACETINE-BAYER Antipyretic: Analgesic.

PHENACETINE-BAYER is a true and distinct organic derivative. It is indicated in influenza (*la grippe*); in all fevers, with or without pain; in rheumatism and neuralgia; and in phthisis and pertussis. It acts promptly and is both safe and effective. Supplied in ounces, tablets and pills.

EUROPHEN, as a substitute for iodoform, is winning an enviable place in therapeutics. It has a special value in specific lesions, while as a surgical dressing in ulcerations, open wounds, and septic conditions of the cavities, it has given excellent results. Supplied in ounces.

SULFONAL-BAYER is indicated in all the insomnias and in the cerebral disturbances of insanity. It is a pure hypnotic, a safe and effective remedy, and it does not give rise to a drug habit. For the correct method of administration *see pamphlet*. Supplied in ounces, tablets and pills.

ARISTOL is widely esteemed by physicians for the excellent results it has given in the treatment of all external traumatisms; in cavital lesions, and in many of the dermatoses. As a surgical application, it is safe, inodorous and non-toxic. Supplied in ounces.

EUROPHEN-ARISTOL, a preparation consisting of equal parts of each medicament, is also supplied in ounces.

DESCRIPTIVE PAMPHLETS FORWARDED ON APPLICATION.

W. H. Schieffelin & Co., New York.

"CURIOUS QUESTIONS."

An Encyclopaedia of the Rare and Curious.

Third Improved Edition Now Ready.

"Curious Questions" fills a niche wholly its own. Its mission is to tell you hundreds of things that you ought to know, and don't; to enlarge your conversational powers; to brighten your intellect, and lead you to further research in the best channels of thought, and to keep you from exposing your ignorance on many questions of daily recurrence.

Do not think you are too wise to profit by it, when Rev. Dr. Andrew Preston Peabody, of Harvard University, says of "Curious Questions:"

> **"I find that some of the questions are such as I could not have answered, or have known where to look for their answers. Such a book will be of inestimable service and value to any intelligent person, young or old."**

The new de luxe editions (25 full-page illustrations) are unexcelled for presentations. Prices, $4.00, $6.00 and $8.00 a set.

Sold by subscription through our regularly authorized solicitors, or supplied direct by the publishers. Illustrated descriptive catalogue and sample pages free. *Agents wanted.* Address the sole publishers,

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL & NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

Clinical Lectures.

ECLAMPSIA.*

By DR. ROBERT OLSHAUSEN,
BERLIN, GERMANY.

Gentlemen:—Eclampsia is a disease which for a long time past has commanded great interest from physicians; its obscure origin being by no means the smallest cause for such being the case.

An elucidation of its ætiology, in all probability, will not be by means of clinical research, but rather through experimental methods or chemical examinations of the blood and secretions. Nevertheless, it will be necessary for any theory of the genesis of the disease not to clash with its clinical manifestations, but, rather in the principal points at least, to coincide with them.

I have at hand the histories of two hundred cases of eclampsia, occurring between September 1st, 1885, and April 17th, 1891, at the Royal University's Women's Clinic here in Berlin. After a revision of the clinical manifestations observed in these cases, I will review comparatively the present theories regarding the genesis of the disease.

The two hundred cases upon which I base my observations and conclusions occurred during 2,054 days. This would mean one case in every ten and one-third days, or on an average of three cases in one month.

It has been frequently observed that cases of eclampsia occur in "bunches," and the following table will elucidate this. They occurred as follows:

In 1886, from July 22 to August 15, or in 25 days, 7 cases; from Sept. 12 to Sept. 25, or in 14 days, 5 cases. In 1888, from Oct. 8 to Oct. 23, or in 16 days, 7 cases; from Nov. 22 to Dec. 28, or in 37 days, 8 cases. In 1889, from Jan. 4 to Jan. 18, or in 15 days, 6 cases; from Dec. 5 to Dec. 31, or in 27 days, 8 cases. In 1890, from Feb. 4 to Feb. 28, or in 25 days, 6 cases; from June 22 to July 2, or in 11 days, 8 cases; from July 9 to July 24, or in 16 days, 8 cases; from Oct. 2 to Oct. 15, or in 14 days, 6 cases; from Dec. 5 to Dec. 30, or in 26 days, 6 cases. In 1891, from Jan. 6 to Jan. 29, or in 24 days, 6 cases.

When one remembers that the average number of cases would only be three in one month, one can see how that many of the cases occurred within a short time of each other. This list includes 81 of the 299 cases. It is remarkable also that the most of this "bunching" of cases occurred between the months of October and February. In the above list, between March and August there occur only 16 cases; all the rest occur between September and February, or 65 cases.

Nevertheless, this occurrence of cases at certain times of the year is in part accidental, for if I included all the other cases in this division (193) we would find the difference no longer marked; 88 falling between the months of March and August, and 105 between September and February. Yet this periodical "bunching" of cases seems so remarkable that I cannot regard it merely as accident or coincidence. No explanation can be given for this. The changes of temperature or weather cannot be responsible.

Among the writers on the subject of eclampsia, Delore* is the only one, apart from myself, who has noticed this peculiarity.

Regarding the ætiological factor of the disease, I can only offer additional con-

*Delivered in part before the Berlin Medical Society, December, 1891. Translated from *Volkmann's Collection of Clinical Lectures.*

* Delore, *Lyon Medical* 10, XII., 1884.

firmation to the well-known facts that experience has already taught us.

Among the 200 parturients affected with eclampsia, 145 were primiparæ and 51 multiparæ; the birth number in four cases was not known.

The proportion of primiparæ, according to my own observations, was 74 per cent; Löhlein gives this proportion as 85.4 per cent.* and 75 per cent.;† Schauta gives it as 82.6 per cent;‡ Brummerstadt as 80.5 per cent, ‖and C. Braun as 86.3 per cent.§

Among the primiparæ there were no less than 37 subjects of 28 years or over. The percentage of "old primiparæ being 25 per cent. Löhlein gives a percentage as 29 per cent.

Of the multiparæ 32 had borne two to four children, while 19 had given birth to five or over. These included 5 who had borne ten or eleven times.

Among the 200 cases there were 16 cases of twins, making 8 per cent. instead of the usual proportion of 1¼ per cent. in normal births. Löhlein gives the percentage of twins in eclampsia as 4.7 per cent.,** Winckel as 11 per cent.†† and Schauta as 7.9 per cent.‡‡

Regarding the number of patients taken with eclampsia during pregnancy before labor, I would not care to give any figures as a result of my own experiences. Nearly all the patients that came under my care had had more or less numerous attacks before being brought to the clinic, and the most of them were in labor. Lohlein considers that 4.7 per cent. develop the disease during pregnancy; Schanta places this number at 14 per cent. Winckel at 23 per cent. and Braun at 24 per cent. The cause of difference in these figures is easily understood, when one stops to consider that at the time of the physician's examination it is often impossible to determine with positiveness if the birth was already underway or not. With but very few exceptions the birth and eclampsia begin within a short time of each other.

According to my belief the high percentage of Braun comes nearest the truth, but it is also too low. An examination of the fœti born eclamptically will make this almost a certainty. When we regard the number that are reported as premature births, or accept as such all children weighing less than 2,250 grammes (less than 2000 grammes for twins) still the true number of premature births will be underrated. Nevertheless out of 161 in which I was able to make this investigation, 49 were found to be premature, or 30 per cent.

In the majority of these cases both the weight and length of the fœtus was so small that even the eighth month of pregnancy could not have been reached. Only 5 out of those specified as premature births, ever reached the weight of 2000 grammes. It seems, therefore, that the percentage of 30 per cent., is far too small, and that the actual number of premature births would reach to 40 per cent. or over. This can be easily explained by the frequent occurrence of the disease during pregnancy, and the then almost immediate occurrence of labor.

This fact is of great importance in the consideration of the various theories that have been advanced concerning eclampsia. But at present it is not sufficiently well known or authenticated. Yet, in Fenstell's* dissertation on the subject we find that in 80 cases of eclampsia he regarded the percentage of premature births as 37.75 per cent.

I will also state that I have observed eclampsia in the third and fourth months of pregnancy.†

The percentage of *sensu strictori* in puerperal eclampsias can be accurately determined. Among these should be included all those cases occurring during the after-birth period. So, among my 200 cases, I found a percentage of 14 per cent. Similarly, Winckel found 17 per cent.; Löhlein, 23 per cent.; Schauta, 26.4 per cent., and C. Braun, 24 per cent.

Among my cases there were five in which the eclampsia occurring during pregnancy passed without causing the birth of the fœtus. But all five—partly at home and

partly at the clinic—gave birth to macerated fœti later on, but without any recurrence of the eclamptic attacks. Our cases have shown that if eclampsia occurs during pregnancy and passes without causing the eruption of the fœtus, it will not recur again at the birth of the fœtus.

It usually occurs in connection with the death of the fœtus,* and from this fact the theory may be deducted that eclampsia may be due to an intoxication produced from the living fœtus. Against this theory, however, is the fact that in many cases eclampsia does not occur for a half a day or longer after the birth of the child; and, apart from this also, from the fact that it not infrequently occurs until long after the death of the fœtus in the womb.

Among my cases such an one occurred. The patient was a primipara, thirty-two years old, who after four eclamptic attacks, occurring on August 7, gave birth to a greatly macerated fœtus on August 10. The woman was in the eighth month of pregnancy. After two more attacks, one on August 17 and 18, respectively, the patient recovered. The urine contained large quantities of albumin, cylinders, and renal epithelium. The treatment consisted in the exhibition of 0.03 gramme of muriate of morphine after the fifth, and 0.06 gramme after the sixth attack, and also 3.0 grammes of chloral by the rectum, in injection.

Braun has also reported two cases of eclampsia occurring when the fœtus was already macerated. That after the death of the fœtus the eclampsia does not recur at its subsequent birth, may be explainable by the almost constant and rapid decrease of the volume of the uterus after its death.

Although the return of eclampsia, which has ceased for twenty-four hours, is rare it occasionally occurs, nevertheless. We had experience with such a case. The patient was a primipara, twenty-one years old, who on the day of the birth of a living, yet undeveloped child (weighing 1,360 grammes and measuring 40 centimetres in length), on May 24, 1887, had several eclamptic attacks. The treatment consisted in the administration of 0.02 gramme of morphine and 3.0 grammes of chloral. The eclampsia returned on May 31, the seventh day after the birth of the fœtus. At this time she had two attacks. Morphine in 0.04 gramme doses was given. Eight days later (June 8) she again had a single attack. The urine was rich in albumin (two-thirds of its volume), and contained also many hyaline and granulated cylinders. The patient recovered.

Another similar case I experienced in former years. In the case in question, after eleven eclamptic attacks of puerperal eclampsia there occurred a cessation of the disease for thirty-six hours. Then, after a palpation of the uterus, a thirteenth and fourteenth attack occurred and, twenty-four hours later, again after the palpation of the uterus, the fourteenth attack. This was followed by additional convulsions, occurring the one after the other, until after the one hundred and fourth attack the patient died.

Leudet* also reported long ago, a case of eclampsia which passed, and the albuminuria even disappeared. Yet the disease returned again after a lapse of two months.

Return of eclampsia at a subsequent, or later child-birth is also a great rarity. Out of the 200 cases with which this article deals, the previous histories of only two cases, showed that they had suffered from eclampsia before. The one case was a secundipara, twenty-six years old, in which the first attack occurred thirty hours post-partum. The urine was highly albuminous. After a few attacks the urine was also found to contain blood-corpuscles, hyaline and granular cylinders. She ultimately recovered, after having eight attacks, which slowly followed each other during the course of twenty-four hours.

The second case was that of a woman, twenty-seven years old, who had given birth to five children. During the course of twenty-six hours, she had nine eclaptic convulsions. The urine was completely saturated with albumin, and hyaline cylinders. The eclampsia ceased, but the patient died twenty-four days later. At her first child-birth she had also had eclampsia.

I also recall a third case from my own practice, of return of eclampsia at a later birth. It occurred in a pregnant women, who had all the symptoms of an uncomplicated chronic interstitial nephritis. These symptoms included, copious diuresis,

* Winckel, *Lehrbuch der Geburtshülf*, 1889, page 587.

**Gazette Hebdom.* 1854, I, 28.

moderate albuminuria and hæmorrhages of the mucous membrane. There were no evidences of any acute process. The patient also recovered from the second attack of eclampsia, but died six months later from atrophy of the kidneys.

Lumpe* had occasion to observe eclampsia at the first, second, and fifth childbirth of the same woman.

I have little to add to the symptomatology of eclampsia. Regarding the prodroma, I would lay stress upon the frequency of the so-called "stomach-ache" together with the much more frequent, indeed almost constant, headache. The meaning of this gastric pain is entirely obscure to us. The symptom is, however, one of great importance; for in the advanced months of pregnancy, when associated with headache, almost may be regarded as a positive prognosis of eclampsia. At least such is our experience. This gastric pain might be explainable by the theory that some patholgical substance is brought into contact with the mucous membrane of the stomach, where it not only causes pain, but more frequently vomiting. This idea seems not to be without good foundation, especially when the experiments made in the Hitzig Clinic in Halle, are taken into consideration, and their discoveries applied in this case. Here it was found that after subcutaneous injections of morphine, the drug was partly secreted upon the mucous membrane of the stomach.

As a prodromal symptom, in one case I have seen amaurosis occur while consciousness still remained. Very soon after this the first eclamptic attack occurred.

Regarding the single later attacks, it is well known that they occur without any warning whatever. Neither can I recall any literature on the subject that says differently. It was all the more astonishing, therefore, that we observed three cases in which there was an undoubted *aura*. In the one case the patient was able to state most precisely that before the attack she felt a sensation of falling. Indeed, she once called out, "I am falling!" and immediately after a convulsion occurred. The same feeling was complained of by another patient—a case of puerperal eclampsia—only that she felt this sensation after the eclampsia had left her. In all she had twelve post-partum convulsions. Simultaneously with the sensations named she had ocular and aural hallucinations. Recovery ultimately resulted.

In the second patient with *aura*, this was still more remarkable. The case was that of a primipara, twenty-one years old, who had six post-partum eclamptic convulsions. She had the sensation of clonic spasms in the extremities and, indeed, simulated the characteristic movements of the arms similar to those observed during the convulsions prior to the attack. Yet, it was only before three of the attacks that she was able to give this index as to their advent. Before the other three she had no warning. In this case it may not have been so much a case of *aura* as that of maintenance of consciousness during the first part of the attack, and this would explain why, after the third attack, deep coma and no *aura* occurred. I need scarcely add that both of these cases were those of undoubted eclampsia. The first patient gave birth to twins and, prior to their birth, had seven convulsions in nine hours. The attacks were quite typical, and the urine contained large quantities of albumin. The patient recovered.

The third case was that of a multipara, twenty-five years old, who had given birth to three children. After an easy and spontaneous birth of twins, perhaps after the lapse of half an hour, the patient suddenly loudly called the name of her husband, and immediately afterwards had the first attack of eclampsia. An hour and a half later, after she had suddenly called out, "It's coming!" she had the second attack. After three subsequent attacks the eclampsia ceased. Even the next day the urine contained a large amount of albumin and a few hyaline cylinders. The second day after the eclamptic attacks the patient developed psychosis with delirium from the poisoning. These symptoms lasted two or three days, after which she made a good recovery.

Regarding the conditions of the urine, as found in the cases observed by me, these differed from those observed by some other investigators, in so far that an abnormal condition was much more constant; indeed, almost exceptionally present. Out of the histories of the 200 cases, in 32 cases nothing is said regarding the nature of the urine. This is partly explainable by the fact that in several cases even catheterization would fail to bring any urine from

*Braun's *Lehrb. d. gebh.* 1857, page 486.

the bladder. Out of the remaining 168 cases, in four cases only a very small amount of albumin, or, perhaps, only a trace, was found. All four were primiparæ; the one had only one attack; the second, three convulsions, ante-partum; the third, four convulsions, post-partum. All three could only be considered light cases. The fourth of these patients, however, who had hydramnion, had twenty-three cases in five and one-half days, and an hour and three-quarters after the last attack, was delivered by means of the forceps of a fœtus which had recently died. She recovered.

Entire absence of albumin was only observed in one case. The patient was a multipara (having given birth to seven children), forty years old, and had seven eclamptic convulsions.

In the remaining 163 cases the quantity of albumin in the urine was always considerable. In the large majority of these cases it was very copious, so much so that in a test-tube filled with urine the albumen would occupy half the space, or in some cases completely coagulated the entire bulk of the urine.

Fenstell* found albumin present in 79 out of 80 cases of eclampsia.

Unfortunately, I can say but little regarding the presence of formed elements in the urine, since the examination in this direction was often neglected, and still more frequently not noted. In 59 cases, in the histories of which these data are given, a negative finding occurred only in seven cases. In the remaining cases there were more or less greater numbers of sometimes hyaline and sometimes granulated cylinders. Often renal epithelial cells were found and, in four or five instances, blood corpuscles as well.

Regarding the presence of œdema, in 40 cases we have histories of its presence before the eclamptic attack. In 26 cases, according to the statement of the patients themselves, the œdema had appeared a few weeks previously; in 11 other cases it had existed for two or three months. In two cases the œdema is said to have been present for five months, and in one case even six months.

In the large majority of cases it was undoubtedly not the question of any long standing circulatory disturbance. This view of the case agrees with the usually tense nature of the œdema, together with the slight amount of swelling.

Icterus occurs but very rarely, and was observed in only two cases. The one case was a most severe one with fatal issue; the second was a lighter case, ten convulsions occurring after the birth of living twins, and the result being recovery. C. Braun recognizes the recurrence of icterus and speaks of a cholæmic eclampsia. Latterly, Stumpf has again called attention to this complication, which most probably is connected with a vascular rupture and hæmorrhage in the substance of the liver.

Before going on to a consideration of the pathological anatomy of the disease, I would say a few words on the loss of memory which I have noticed among patients recovering from eclampsia; occurring not only from the time of the first attack until the return of consciousness, but stretching into the period of convalescence, and often occurring a number of hours before the appearance of the disease.

In my experience, I met the patient whom I first saw twelve hours before the first attack and who, during a long consultation, talked most rationally and was in the full possession of her faculties. Yet, after her recovery from the eclampsia she had no recollection of either the consultation or other important events that occurred within twelve hours of the first attack.

This loss of memory might, under certain circumstances, be of legal importance.

(*To be continued in the next issue.*)

Loc. cit.

THE MANUFACTURE OF ARTIFICIAL ICE.

Ice was artificially produced in India long before the invention of machines for the purpose, a fact not generally understood. In the upper provinces, water was made to freeze by exposing it during cold nights, in porous vessels, or bottles wrapped in a moistened cloth. In Bengal, shallow pits were dug and filled nearly full with dry straw on which were set flat, porous pans containing the water tobe congealed. Exposed over night to a cool wind, the water evaporated at the expense of its own heat, and the consequent cooling took place with sufficient rapidity to overbalance the influx of heat through the cooled air above, or through the badly conducting straw below.

OPHTHALMIA NEONATORUM.

By C. A. VEASEY, M. D.

OPHTHALMOLOGIST TO THE PHILADELPHIA LYING-IN CHARITY AND NURSE TRAINING SCHOOL; ASSISTANT DEMONSTRATOR OF SURGERY IN THE JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA, ETC.

A LECTURE BEFORE THE NURSE CLASS, THE MEDICAL STAFF, THE BOARD OF MANAGERS AND INVITED GUESTS OF THE PHILADELPHIA LYING-IN-CHARITY AND NURSE TRAINING-SCHOOL.

Ladies and Gentlemen.—When invited by the executive committee of your institution to deliver a lecture this evening upon "Ophthalmia, its causes prevention and treatment," I was in doubt as to whether I should attempt to treat of all the varieties of ophthalmia, or only of some particular variety that you would perhaps come in contact with more than any other; and after due consideration I arrived at the conclusion that it were better to talk of that variety which you will see more of as obstetrical nurses, so that you will recognize it when you see it and understand its causes, prevention and treatment.

The socket in which the eyeball is placed is lined by a mucous membrane known as the conjunctiva. This membrane commencing at the outer edge of the lids extends backward for a considerable distance, and is then reflected forward on the eyeball, that portion covering the lids being designated the palpebral conjunctiva, and that part covering the eyeball, the ocular conjunctiva. Now, ophthalmia is a disease of the eye, characterized by pain, redness, intolerance of light and excessive flowing of the tears, there being either a hyper-secretion or a genuine discharge, according to the variety; the inflammation for the most part being seated in the coats of the eyeball, or conjunctiva. The affection is sometimes known as conjunctivitis.

Varieties.—The varieties of ophthalmia are many, the chief among them being simple, muco-purulent, purulent, diphtheritic and phlyctenular, the difference between them being more the degree of inflammation than the character of it.

Simple, or as it is sometimes called palpebral conjunctivitis, is an inflammation of the palpebral folds of the conjunctiva, that portion which covers the eyeball itself not being affected. It is characterized by redness, intense itching, burning and a sensation as if small grains of sand were under the lids, causing a desire to rub the eye continually. The causes are numerous and varied—such as extremes of temperature, this being the case when people tell you they have taken cold in the eyes; foreign bodies, as pieces of coal dust or of shell which are blown into the eyes as one walks along the street; cinders from the locomotive of a railway train; exposure to a vitiated atmosphere—a room filled with tobacco smoke for example; loss of sleep, as I am sure many of you have experienced after you have been nursing a tedious case all night without having had your sleep on the previous day. And one of the chief causes is working without glasses when the eyes need them, or working with improperly fitted glasses. Indeed, we frequently have patients come to our offices complaining of nothing else but the burning sensation in the eyes, with agglutination of the lids upon waking in the morning, and almost always there is found some error of refraction which when corrected by proper glasses, the other symptoms disappear.

And these glasses should not be prescribed by an optician but by a skilled oculist, who has made a study of the eye from a medical and surgical standpoint—in other words, a graduated physician who has made a speciality of the diseases of the eye. It is frequently remarked by elderly persons that when they were young, glasses were not used nearly so much as now. To be sure they were not, but at that time there were not the educational advantages to be enjoyed as now. The child was not sent to school at so tender an age, and urged to work day and night in its endeavors to excel and gain a high degree of distinction. So many people did not gain a livelihood by the constant use of the eyes then as now. There were fewer professional men, fewer scholars—in other words, there was less eye work, and consequently less eye strain and glasses were not required.

The present age is one of push, energy and ability, and to obtain a position in, or near, the front ranks of the vast army of people who are constantly pushing forward in their endeavors to reach the highest mountain peak of success, requires much

persevering labor. It is almost impossible to attain any degree of distinction, in the present age, without at least a moderate general education; and an extensive education in one's particular vocation is absolutely necessary. To possess this requires much time and considerable use of the eyes, and in our efforts to hasten our success and excel our comrades, to reach the summit for which we have been striving, as quickly as possible, we use them inconsiderately; hence the weak eyes of ourselves and our children, to remedy which we are compelled to prescribe glasses, which correct the defects and relieve the ophthalmia and the strain. Unless the cause of the ophthalmia be removed, the disease in a short time becomes chronic, and the treatment is more or less prolonged; but if taken early, the cause searched for and removed, the recovery is rapid.

The muco-purulent variety is really an exaggerated form of the simple, the difference, as stated above, being only in degree. In fact the causes are the same, to which may be added contagion, the material having come from some other eye and having been transmitted either through carelessness in not cleansing the hands, or perhaps by means of a towel or handkerchief, this frequently being the method of inoculation.

The purulent is an exaggerated form of the muco-purulent, the dose of the poison, as it were, having been larger, the soil more susceptible and the discharge being pus.

The diphtheretic is a variety, fortunately for us, rarely seen in this country. As all diphtheretic inflammations it is characterized by the formation of a membrane, in this instance it being on the conjunctiva, and very adherent. The affection is inclined to be epidemic and is one of the utmost gravity.

The phlyctenular has the same symptoms as the muco-purulent, but is especially characterized by the appearance of small phlyctenulæ, or vesicles, on the ocular conjunctiva, and it is from these that it takes its name.

The muco-purulent and the purulent varieties, when occuring in the new-born child, are grouped together under the head of *Ophthalmia Neonatorum*, the variety that is of particular interest to you as obstetrical nurses, and to all who are connected with a Lying-in Hospital; and I have passed over the other varieties rapidly, each one of which would afford material for a whole lecture, merely mentioning a few of their chief symptoms, so that we might discuss this one at greater length. To be sure, gonorrhoeal ophthalmia is to be classed with the above group, but as this is only purulent ophthalmia from a specific cause it is hardly necessary to make another variety. The fewer the varieties the more easily understood is the disease.

As in all cases of ophthalmia, the real cause of ophthalmia neonatorum is a germ, just which particular one has not yet been fully determined, and the inoculation which takes place in one of two ways has been divided into the primary and secondary, the former taking place during, or immediately after, birth; the latter occurring in those cases in which there has been a sufficient length of time since the birth of the child to enable us to be sure that the affection is a result of post-partum inoculation.

The primary inoculation may be made in several ways. It frequently occurs in making manual examinations in face presentations; the eyelids are sometimes opened by instruments, allowing the vaginal discharge to enter; the mucous is sometimes retained on the lids after birth, sufficient care not having been taken to cleanse them thoroughly, and at a later period entering the eye causes the dreaded inflammation; and again, a very frequent cause is the direct introduction of the contagious material caused by the opening of the eyelids by the tense perineum as the head is passing through the external orifice. This may at first seem to you to be improbable, but when you consider for a moment how very tense the perineum is and how the head is elongated, causing the eyes of the child to bulge forward, it is very easy to understand how, in passing over this taut, elastic structure, stretched to its utmost capacity, the palpebral fissure may be opened and the contagion introduced. Clinically it has been determined that males are more frequently attacked than females, owing to the fact that the head is usually larger, and the children of primiparæ more frequently than those of multiparæ, on account of the tediousness of the labor and the lesser degree of perinæal elasticity and the weak expulsive pains toward the end.

The secondary inoculation is caused by failure on the part of the person receiving the new-born infant to cleanse *immediately* everything from the eyelids, in the manner which I will explain to you later; by direct contact with unclean materials, such as towels, sponges, etc., and in a manner that frequently occurs, by bathing the face and eyes with the same water with which the body has been sponged. Of course irritants, like soap, bay rum, bright lights, etc., may cause a mild type of conjunctivitis, but not the horrible ophthalmia neonatorum of which we are speaking.

Symptoms.—The symptoms, which may be divided into four stages, we are all familiar with. First, we have the period of inoculation, which usually is only a few hours; then a short period in which lymph, the exudative material that always accompanies inflammation in any part of the body, is freely secreted, and this is followed by the copious discharge of pus which is virulently contagious. There are present, of course, the characteristic pain, redness, swelling, intolerance of light, and a copious discharge. But if everything goes well the fourth stage is marked by the gradual disappearance of the secretion and a recession of the inflammation.

The pain caused by this affection is of the most excruciating character. To give you some idea how severe it is, an incident that happened several years ago, and has been recorded, is worth relating. At one time a slave ship sailing on the high seas had an outbreak of purulent ophthalmia on board. The ship was some distance from land and there were about three hundred slaves below the decks affected with the disease. No treatment was instituted at this time, but a little later some of them were allowed to come on deck to get some fresh air, and the suffering was so intense that most of those who had been allowed to come up committed suicide by jumping overboard. The great majority of those who did not meet this fate became totally blind.

Progress and Termination.—If no complication presents itself and the disease does not pass into the chronic form, it usually lasts from three to four weeks. If it terminates directly in a cure, all of the symptoms gradually diminish, and the conjunctiva returns slowly to a healthy condition. If any complication arises, however, or if the case passes into the chronic form, the affection becomes one of the greatest gravity. Small granulations begin to grow on the lids and what is known as granular conjunctivitis supervenes, a disease very difficult to eradicate, and the results may be opacities of the cornea, that part of the eye through which we see. This, of course, causes more or less impairment of the vision, and if the disease progresses it may result in a perforation of the cornea, or ultimate blindness.

Prognosis.—The prognosis of ophthalmia neonatorum is not so bad as one would at first suppose it to be. But as complications may, and do, arise at any stage of the disease, and as it is, as before stated, the cause of more blindness than any other single factor, it is almost criminal to neglect those precautions and that practice which experience has shown us reduces the percentage of cases almost to *nil*.

Treatment, Prophylactic.—The treatment of this disease is divided into two parts prophylactic and curative. In the former division come all of those means which are used to prevent the disease. First of all the laity should be instructed concerning the great danger of ophthalmia and that as soon as any inflammation of the eye of the new-born occurs, no matter how slight, it should at once be reported to a regular practitioner. This idea is put into execution in many foreign countries, so well understood is the danger of the disease, and in Sheffield the eye infirmary distributes cards which read as follows: "If a baby's eye run with matter and look red after birth, take it *at once* to a doctor. *Delay is dangerous* and one or both eyes may be destroyed if not treated *immediately*." This advice cannot be too greatly emphasized, and it would be an excellent step towards the prevention of much blindness if all, or indeed some, of our infirmaries followed the same practice. Better still if our municipal authorities would take the matter in hand and distribute printed circulars to each family, explaining the dangers of the disease and stating what should be done in case of an attack of it.

In some countries stringent regulations have been adopted as regards midwives and nurses, which are not only a protection to the infants but also to the nurses, as by following stated directions they are freed

from all blame. In New York state the following has recently been enacted: "Should any midwife or nurse having charge of an infant in this state notice that one or both eyes of such infant are inflamed or reddened at any time within two weeks after its birth, it shall be the duty of said midwife or nurse so having charge of such infant to report the fact in writing within six hours to the nearest health officer, or some legally qualifiad practitioner of the city, town or district in which the parents of the infant reside." Some such law enacted in every state would cause the number of the most hopeless and helpless or all people, the blind, to be reduced in our public institutions.

In the beginning of the second stage of labor the vagina of the patient should be thoroughly irrigated with a solution of corrosive sublimate (strength 1-2000), or a solution of some other germicide as the obstetrician may prefer, but according to my belief corrosive sublimate is the best in use at present. The hands of the physician and the nurse, as well as all the instruments employed, should be thoroughly disinfected. The fœtal eyes should be assisted to pass over the perineum without resting, for, as I have stated elsewhere, ophthalmia is frequently caused by the palpebral fissure being opened during the passage of the head over the tense perineum and the contagion thus introduced. The eyes can be made to pass over rapidly by hooking the middle finger of one hand over the perineum and drawing it downward.

As soon as the head is born, if there is time, the eyes should be wiped with small pieces of absorbent cotton or wool; and if there is not time before the birth of the body, it should be done before the cord is tied. In doing this the cotton should be loosely packed into small pledgets and the eyes very gently wiped from above downward, which will facilitate the removal of any foreign material that may have accumulated around the eyeball. As soon as this is finished two drops of a five-grain solution of nitrate of silver should be dropped into each eye, though of course this cannot be done without the order of the physician in charge of the case, and I regret to be compelled to add that many do not seem to think it is necessary to take any such precaution, notwithstanding the fact that statistics show this disease to be the greatest known cause of blindness, and that when the above prophylactic treatment is used the percentage is reduced from ten per cent. to almost *nil*.

The above is known as the Crédé method, which has been slightly modified, the original being to instill one drop of a ten-grain solution of nitrate of silver into each eye. Ascertaining that as a rule this solution was stronger than required and excited too great a degree of inflammation, it is my custom to have instilled into each eye two drops of a five-grain solution, which, though it may contain the same amount of silver, does not affect the conjunctiva so severely as does the stronger solution.

There is another method, known as the Hégar-Korhn, which consists in wiping the face and eyes immediately after birth with a solution of corrosive sublimate (strength 1-1000), and though statistics show very good results, I prefer the instillation of the astringent, believing it to be the surer and better method of prevention. In one thousand cases treated by the Crédé method not a single case of ophthalmia developed, while without it about 10 per cent. of all infants are affected with the disease. In the foundling hospitals of Paris the percentage of cases twenty years ago was from 80 per cent. to 90 per cent., while to-day it is 0.2 per cent., it being compulsory to use the Crédé prophylactic treatment.

The face of the child should never, under any circumstances, be washed with the same water with which the body has been bathed, and different sponges or pieces of flannel should be used for the face and body. The reason is understood without being given.

It is very important that you should always wash your hands thoroughly after adjusting the mother before you touch the child, and you should guard against exposing it to any draughts, bright lights, etc., or allowing any soap to get into the eyes.

Curative.—Should you be so unfortunate as to have the disease occur the child must be isolated at once, and the physician notified.

If one eye only is affected the other should be guarded by covering it with a light bandage. The physician will instruct you to cleanse the eye every hour (perhaps more or less frequently than this, depending entirely upon the severity of

the case) washing it first with warm water then with a solution of boric acid.

The best way to do this is to have some one sit in front of you and hold the child so that its head rests between your knees, with its face looking upward, your lap being protected with a piece of gum cloth or a towel. The person in front holds the child's legs under her left arm and supporting the body on her raised knees, has her right hand at liberty, with which to assist you. In this position the eyes can be irrigated and the applications made to the conjunctiva with the least possible trouble.

To reduce the inflammation cold compresses are used. I prefer to have these made out of small pieces of lint, about the size of the one I show you here, and kept on ice which cools them more thoroughly than water. They should be placed on the eye four in thickness and at first they should be changed every minute, the time between the applications being gradually lengthened. The compresses not only reduce the inflammation by processes which I will not describe to you this evening, and which are readily understood by every practitioner; but it is also claimed that they either destroy or prevent the development of the germ that causes ophthalmia, it having been proved by experiment that the said germ cannot develop at, or below, a temperature of 32° F.

The eyelids are everted at stated intervals by the physician and applications of a solution of nitrate of silver made to the mucous membrane, great care being taken to apply it to all the folds. This stops the growth of the germs and substitutes a healthy for non-healthy inflammation.

Other applications rather than nitrate of silver are frequently made, among them being insufflations of iodoform, calomel and solutions of tannin, corrosive sublimate, peroxide of hydrogen and many others too numerous to mention. In my own experience I have always found the solution of nitrate of silver to be the best, though it should not be used indiscriminately, nor applied, as many advise, with a camel's hair brush; but small pieces of cotton should be rolled on the end of a stick, as I show you here, dipped into the solution and touched to all parts of the conjunctiva, one being used for each eye, and burned immediately afterward, as should be all the pieces of cotton or lint which come in contact with the eye. But no method will be of avail unless the physician is ably supported by the nurse in the thorough and frequent cleansing of the eye; for no matter what the character of the applications may be they will not rid the eye of the micro-organisms nor prevent their multiplication unless the nurse, with whom the case is entrusted, keeps the organ cleansed of all discharge during the intervals between the applications. And when you have become tired and weary and exhausted from nursing such a case and feel disposed to neglect it, even if only for a few moments, let me beg of you to look at the subject from a humane point of view, for I know of no act of charity or benevolence more praiseworthy than that of saving the eyesight of an infant unable to help itself, and thus preserving its future usefulness for its family, for mankind at large and for its Maker; and in after years when that same infant, now grown to manhood or womanhood, is able to realize the escape it had from blindness, much of which was due to your careful nursing and your faithful attention, though you may not be aware of it, he will heap upon your head heartfelt blessings and praises, such as we all desire and can only obtain through our own efforts.

I have added to these remarks some suggestions collected from various sources which I have placed together as so many rules. In giving them to you I do so in part as a recapitulation, and perhaps am guilty of repetition; but if in so doing I am enabled to impress upon your minds some important facts relating to the disease and its prevention, so that you will in the future use them, I feel quite confident that you will assist very much to lessen the number of cases of ophthalmia neonatorum, and thereby in reducing the number of blind in our public institutions; and the purpose of my lecture will have been accomplished.

1. Before making a vaginal examination always cleanse the hands thoroughly with soap and warm water, followed by some antiseptic solution, taking care not to forget the finger-nails.

2. During labor assist the eyes to pass rapidly over the perineum.

3. Always cleanse the eyes of the infant in the manner I have explained to you *immediately* after birth.

4. Do not use the same water, for bath-

ing the face and eyes, with which the body has been bathed, and always use different sponges or pieces of flannel.

5. Never employ one towel for two persons. Let everybody have his own.

6. Be careful not to allow any soap or bay rum to enter the eyes.

7. Keep the light in the lying-in chamber very dim, or have it shaded with some dark material, green being the least trying and the most restful to the eyes.

8. Always burn *immediately* everything that has come in contact with the ophthalmic discharge.

9. Instruct the laity, whenever the opportunity presents itself, of the great danger of ocular affections of the newborn, and the necessity of consulting a physician as soon as they are discovered.

And to the members of the profession present I would add:

10. Always use the Crédé, Hégar-Korhn or some such method of cleansing and stimulating the eyes of a new-born infant.

EYE AFFECTIONS IN MALARIA.

Bagot (*Ann. d'Oculist.*, January 1892) records the following cases which occurred at Guadeloupe. The first patient was a mulatto boy of 15, who had a severe bilious remittent fever with gastro-intestinal symptoms and coma; this lasted two or three days, and immediately afterward his sight began to be affected; three months later it was found that he had a soft cataract in each eye. The second patient was a mulatto girl of 16, who also had an attack of grave malarial fever lasting three days, and immediately afterward her sight began to fail; nine months later she also was found to have a soft cataract in each eye. The third case was that of a little white girl, who had an attack of malarial fever with delirium, convulsions, and loss of consciousness lasting two days; then, for a whole day she complained of red vision, and after that her sight rapidly deteriorated until the fifth day, when she was absolutely blind. An incomplete opthalmoscopic examination at this time revealed a retinal hæmorrhage in the neighborhood of each macula. A year later she had atrophy of both discs; with the right eye there was perception of light; the left had improved more and she could see to go about, and had fairly good color perception.—*Brit. Med. Jour.*

Communications.

DIPHTHERIA.*

By E. FLETCHER INGALS, A.M., M.D.,
CHICAGO, ILL.

Diphtheria may be defined as a specific contagious disease, characterized by pronounced constitutional symptoms and inflammation of the mucous membrane of the fauces and upper air passages, with exudation of inflammatory lymph, which rapidly becomes formed into false membrane.

It has long been recognized as one of the zymotic fevers. Many English authors consider it a constitutional disease with local manifestations, but among continental physicians and American writers there are many who regard it as a primary local affection with secondary constitutional symptoms. Personally, I am inclined to accept the former view, and can see no more reason for regarding this as a local disease than for regarding vaccina in the same light. To me, the peculiar false membrane formed in the fauces appears analagous to the peculiar vesicle developed after inoculation with vaccine virus; and the fact that there is a distinct period of incubation extending sometimes over many days before there is any development in the fauces, together with the fact that in some instances the disease runs to a fatal termination within a few hours and before there has been any appreciable local manifestations, seems to prove this position.

The disease manifests itself in the throat by hyperæmia, soon followed by the exudation of inflammatory lymph and deposit of false membrane in one or more places upon the surface, and this membrane may ultimately extend to the air passages or may be found upon wounds which may exist in other parts of the body. Upon post-mortem examination of those dead of the disease, blood clots are usually found in the heart or large arteries. The lymphatics at the angles of the jaw are enlarged and the kidneys are generally deeply congested. Various bacteriæ have been found in the mouth of those suffering from diphtheria, most of which, however, may also

*Read before the Illinois State Medical Society, at Vandalia, May, 1892.

be found in the buccal secretions from healthy individuals.

Ætiology.—The disease is undoubtedly contagious and may be transmitted from man to lower animals and vice versa, but the degree of contagiousness varies in different epidemics. The affection is generally believed to be due to a specific micro-organism, the identity of which is not as yet fully established. The researches of Pruden in 1869 pointed to a streptococcus as the probable cause of the disease. but most bacteriologists now attribute it to the Klebs-Loffler bacillus. This bacterium is a microscopic rod about the length of the tubercular bacillus, but twice its thickness It is usually more or less bent, with rounded extremities. one or both of which may be thickened. giving the club or dumb-bell appearance. It is immobile and contains no spores. These bacilli do not readily absorb the common analine stains, but may be colored by the solution of Loffler's methylene blue, the coloration often being most intense at the extremities. According to Amand Ruffer, these bacilli are found most abundantly in the superficial portions of the false membrane, and nearly all experiments go to prove that they do not often enter the lymphatics or blood vessels. Therefore, of itself, the bacillus is apparently innocuous, but it secretes a virulent toxalbumen or ptomaine easily absorbed, which, when injected into the circulation, produces constitutional symptoms similar to those of diphtheria. Numerous clinical observations and experiments have, however, demonstrated with an equal degree of certainty that pseudo-membranous inflammation is often produced independently of this bacillus, as for example, that resulting from surgical injuries to the throat, or various chemical caustics; and they have also shown that certain exudative inflammations supposed to be of microbic origin, as for example, those frequently observed in scarlet fever and measles, are not attended by the development of the Klebs-Loffler bacillus. These latter inflammations have been termed psuedo-diphtheria, and it is stated that they can only be distinguished from true diphtheria by the absence of the Klebs-Loffler bacillus, by their being followed by paralysis, and by not being attended by a peculiar form of albuminuria which occurs in true diphtheria independently of dropsy or uremic poisoning. The necessity for assuming that there are two varieties of diphtheria, seems to me to justify the statement made in the beginning, that the identity of the micro-organism, which is supposed to cause the disease is as yet uncertain.

Primary inflammation of the fauces apparently greatly favors the development of diphtheria, and its development and progress seem to be largely influenced by bad hygienic surrounding, such as impure drinking water, sewer gas, and the emanations from decaying vegetables and unclean cellars; but it is doubtful whether any of these conditions can of themselves produce the disease.

The most frequently predisposing cause of diphtheria is exposure to cold, more particularly in the spring and fall months, when the temperature of houses is liable to be kept at from 65° to 68° F. At this time adults moving about the house do not realize the necessity for fire, but the little children upon the floor are exposed to a temperature two or three degrees lower; or during the morning or evening, they are allowed to run about for sometime in their night clothing and thus contract colds, which are peculiarly prevalent at these times and which favor the development of diphtheria.

Symptomatology.—After a period of incubation varying from one to eight days, this disease is usually developed in young children with pronounced constitutional symptoms, such as headache, drowsiness, fever, thirst, and sometimes vomiting and diarrhœa. The little one usually complains of stiffness of the neck, and within a few hours of sore throat. In older children or adults, the symptoms are commonly much less pronounced, and the disease develops more gradually;the sore throat is attended by sensations of dryness and slight pain, with an inclination to frequently hawk and clear the throat. Usually within twelve to thirty-six hours a false membrane begins to form upon the tonsils and in rare instances an erythematous eruption appears upon the skin. The pulse is rapid and as the disease progresses, becomes small, feeble and intermittent. The temperature at first seldom rises above 101° or 102° F., but on the appearance of false membrane it usually falls and may even become subnormal. During the third or fourth day of the attack it is likely to rise again, indicating in favorable cases sup-

puration and oxfoliation of the false membrane; or in those which are progressing unfavorably, extension of the disease to the larynx, the lower air passages, or to the intestinal canal. A sudden fall of temperature after four or five days is a symptom of grave import. When the disease extends to the larynx the voice soon becomes affected and may be weak and hoarse even before the false membrane is deposited, but with the deposit of pseudo-membrane upon the vocal cords the voice becomes aphonic, the cough less intense, and dyspnœa develops proportionate to the amount of obstruction. In this condition the respiration becomes noisy and stertorous and the dyspnœa is constant, aggravated from time to time by spasms of the laryngeal muscles. With these paroxysms all the distressing symptoms of suffocation appear.

The deposit of false membrane frequently extends to the naso-pharynx or nares, causing obstruction and a sanious discharge, and later epistaxis. The tongue is commonly heavily coated and there is a peculiar odor of the breath, which is almost pathognomic. Anorexia, nausea, and vomiting are common, especially when the kidneys are much involved, and albuminuria is present in nearly all cases from early in the disease. The glands of the angles of the jaw are enlarged, and as as a rule, the greater the swelling, the more severe will be the attack. Inspection of the throat reveals: first, congestion; and shortly after, thin strips of yellowish-white false membrane, which rapidly extend over one or both tonsils, and in more severe cases, to the surrounding mucous membrane. With the progress of the disease, the membrane becomes grayish, brownish, or even almost black in color. It has the appearance of involving the mucous membrane and being slightly elevated above its free surface. When exfoliated, or forcibly removed, an ulcerated granular or bleeding surface will be found beneath it, though not usually co-extensive with the false membrane. When the glottis becomes obstructed, the respiratory movements become slow and labored and recession of the soft parts of the chest above the clavicles, at the ensiform appendix, and over the false ribs is noticed with each inspiratory movement. The skin is cold and pallid, and may be bathed in cold perspiration. The lips, finger nails and ears appear livid, and as the carbonic acid poisoning progresses, the patient may become extremely restless, or fall into a semi-comatose condition. With the paroxysmal spasms of the glottis, the well known symtoms of imminent suffocation are developed and death may speedily ensue.

Diagnosis.—Diphtheria is not likely to be mistaken by the experienced physician for any disease except follicular tonsillitis and simple membranous sore throat; though in some cases, it may be a difficult matter to distinguish between diphtheria and the pseudo-membranous forms of scarlatina or measles. The essential points of difference between diphtheria and follicular tonsillitis are; in follicular tonsillitis there is higher temperature, commonly two or three degrees more than that of diphtheria; there is much more pain in the throat, and difficulty of opening the mouth which is not usually present in diphtheria, the swelling of the tonsils is greater, and there appear a number of small yellow spots where secretions have collected in the follicles, instead of one or two uniform patches of false membrance spreading over a considerable part of the throat.

In simple membranous sore throat, at first there are numerous herpetic vesicles, but after two or three days these are covered with a membrane similar to that of diphtheria, though it is not so thick and more easily removed. Commonly also, there are several patches of this false membrane, and herpes labialis is apt to occur at the same time. The pain is simple membranous or as it is sometimes known, herpetic sore-throat, is usually very much more intense than in diphtheria.

There is usually no difficulty in distinguishing between diphtheria and scarlatina or measles, but sometimes in either of these affections the deposit of false membrane in the fauces may cause an appearance very like that of diphtheria, There is a question whether in such cases there are the two diseases combined, or whether the pseudo-membrane, as claimed by bacteriologists, is entirely different in its origin from true diphtheretic membrane.

Prognosis.—The prognosis of diphtheria is always grave and we can never assure the friends that the patient is out of danger until he has been well for three or four weeks, because of the serious sequelæ which sometimes follow. I have known cases to terminate fatally within twelve

hours after the beginning of the attack, but in the majority of serious cases a fatal termination does not occur before the fourth or fifth day, and in a considerable number the struggle for life may continue five or six weeks. In some epidemics of the disease a large percentage of patients recover; but in others twenty-five or thirty, or even a large per cent. prove fatal. The deposit of false membrane in the nose, or naso-pharynx, or intestines; the occurence of extreme pain in the ears and throat, of purpuric spots upon the skin, or of epistaxis or other hæmorrhages, and the presence of persistent anorexia, vomiting, diarrhœa or suppression of urine, are all indications of grave import. Patients may die slowly from asthenia or more quickly by suffocation, or they may be carried off by heart failure or convulsions. Not infrequently paralytic symptoms follow the attack about the third week, but except in cases where the respiration or circulatory centers are involved, recovery usually occurs, though it may be delayed for weeks or even months, and sometimes the paralysis is only partially recovered from, more or less loss of muscular mobility remaining permanent.

Treatment.—There are few diseases in which the methods of treatment are more numerous; a fact which may be explained by the great inutility of the majority of means adopted. So much depends upon the condition of the patient when attacked, upon his hygienic surroundings and the variety and nature of the particular epidemic, that physicians are necessarily led astray in estimating the effect of remedies employed. During the early portion of a severe epidemic a very large percentage of patients may die whatever methods are used in the treatment; but later on the cases become less and less severe and the fatality greatly diminishes, regardless of the treatment employed. However, the remedies which are in use during the latter part of the epidemic are liable to receive all the credit.

Whenever diphtheria appears in a household, the greatest care should be exercised to isolate the patient, and all other children should be removed if practicable. The rooms occupied by the patient should be kept carefully closed, the doors covered with sheets constantly moistened by antiseptics, and the patient and nurse should have no intercourse whatever with other members of the household. The sick rooms should be kept warm and thoroughly ventilated, and finally when the attack subsides, the utensils and clothing used in the sick room should be disinfected or destroyed, and the room thoroughly fumigated and aired before it is again used; even then it is well to prevent children from occupying the room for several weeks afterwards.

In the beginning of the attack, ice taken freely into the mouth tends to relieve thirst and reduce congestion and apparently markedly to limit the progress of the disease. Of even more importance has seemed to me the application externally of ice bags or the ice water coil of metallic or rubber pipe applied to the throat. When ice bags are used, they should be narrow and long and should be about half filled with pieces of ice about the size of filberts; the bag may then be folded in a handkerchief and tied so that it will extend up to the ears on both sides. The ice will need to be changed about every hour. Occasionally patients complain of pain when cold is employed and in these, very hot applications will be found to answer a better purpose, but whether hot or cold be used, it must be continuous; otherwise more harm than good will result.

As soon as the membrane begins to separate, hot applications appear to be more useful than cold. The disease usually causes dangerous prostration. Therefore the patient should be well nourished from the beginning. Liquid diet in the form of beef tea, broth, or better yet, milk, should be given at regular intervals and in large quantities; about half a pint or its equivalent being used as often as every third hour. Alcoholic stimulants are recommended early by many practitioners, but to me they seem unnecessary and undesirable until the stage of depression supervenes. Acting on the principle that bacteria cannot live in acid solutions, some physicians recommend the free use of acidulated drinks or gargles, and this possibly explains the reputation recently attained among the laity, by pineapple juice, as a cure for diphtheria. Many substances have been used with the hope of removing false membrane; the simplest of these is steam, which may be impregnated with the time-honored lime water and applied by the croup tent or any suitable atomizer, but it is extremely doubtful whether lime

in any form is ever applied in sufficient quantity to appreciably affect the pseudo-membrane.

Lactic acid is one of the most powerful solvents for pseudo-membrane. It has been highly recommended in about 15 per cent. solution to be frequently employed as a gargle or spray; and in full strength to be carefully applied by the physician twice daily to the false membrane. Tripsin, resorcin and papain have all been used for their solvent effects upon the membrane, but they seem to have little if any influence upon the progress of the disease. Tannic acid and alum are used to astringe the false membrane, and insufflations of sulphur have become extremely popular with the laity, but none of these seem to have much effect upon the disease. Solutions of mercury-bichloride one to one thousand or weaker; of carbolic acid, one to three per cent.; of potassium permanganate, one per cent.; liquor sodæ chlorinatæ, five per cent.; of chloral, about thirty per cent.; or of sulphurous acid, from five to ten per cent., have all been highly recommended, from time to time, as gargles or sprays to destroy the poisonous germs in the throat. Peroxide of hydrogen is also used for the same purpose, either diluted with an equal part of water, or in full strength as obtained from the pharmacist. Tincture of myrrh, strong alcohol, and tincture of the chloride of iron have also been recommended, and occasionally tincture of iodine or a strong solution of nitrate of silver are used. I believe that strong applications often do more harm than good, and any remedy which causes the patient pain for more than five minutes is likely to be injurious. Tincture of iron has seemed to me one of the best remedies for local use, as it has also appeared for internal administration. Recently I have adopted as a local application, either by means of spray or gargle, a saturated solution of boric acid in cinnamon water. The researches of Roux and Yersin in 1889 demonstrated that the toxicity of cultures of the diphtheritic bacillus are greatly diminished by the addition of carbolic acid, borax or boric acid, and the experiments of Dr. G. V. Black, reported in the *Dental Review* for February and March, 1889, have shown that the oil of cinnamon, 1 to 2000, is a most efficient germicide; therefore, a combination of these two appears especially suited to the destruction of the diphtheritic bacillus. This application is neither unpleasant, painful nor dangerous, and from my clinical observation, it appears very effective. My common practice in diphtheria is to give tincture of iron in large doses, about one minim for each year of the child's age, combined with an equal quantity of glycerine and enough syrup of tolu to make one drachm. This dose is administered every hour in serious cases, or once in two hours where the symptoms are less severe. The patient is first given three or four swallows of water, so that the medicine will not prove irritating to the stomach, then the medicine is administered in as concentrated a form as can be taken without causing pain; the patient is directed to hold it in the throat as long as possible, thus obtaining the effect of a gargle, and then it is swallowed. Usually as much as ten minims to the drachm will not cause pain in the early stages of the disease, but later on it may be necessary to dilute the dose with water. The gargle or spray should also be used every hour. Thus, one or the other would be administered every half hour except during the night, when it is often necessary to allow the patient to sleep. However, when the disease is progressing it is sometimes unsafe to allow the patient to go more than half an hour without receiving either the gargle or the solution of iron. But I would strongly deprecate awakening the patient more often than is necessary for this purpose, and as soon as the membrane ceases to spread, I would allow the child to sleep one or two hours rather than disturb it to give the medicine. Quinine in moderately large doses may also be given judiciously, and as the stage of depression comes on, alcoholics should be used freely, it making little difference in the progress of the disease whether they be in the form of wine, whiskey or brandy. Children will often take much more readily than any of these a mixture of equal parts of alcohol and syrup of tolu which is practically of the same strength as good whiskey. When the heart fails, no remedy is of so much value as some of the preparations of nux vomica. The tincture of nux vomica although liable to variation in strength has seemed to me to act more favorably than strychnine. Which ever preparation is adopted it must usually be given in large and frequently repeated

doses; to a child of five years of age I have given one or two minims of tincture of nux vomica, which equal two to four drops, every hour for many days, with the greatest benefit. I should not hesitate as long as the heart continued weak to give half a minim(that is one drop) every hour until the constitutional effects as indicated by twitching of the tendons, were developed; the doses should then be slightly diminished, or the intervals between them prolonged. Within the past few years the bichloride, and other preparations of mercury have been largely used in the treatment of diphtheria in doses often much larger than could safely be administered to adults. I have myself used freely the mild chloride of mercury (calomel), with most happy results in diphtheritic laryngitis, but I have not favored large doses of the other preparation believing that a system already struggling against the virulent action of the toxalbumins is poorly fitted to withstand poisonous doses of bichloride of mercury and its congeners. The mild chloride of mercury has been highly recommended for diphtheria and I have no doubt that it is beneficial, especially as a cathartic. I have found it most efficacious in instances of diphtheritic laryngitis, and have never known it to do harm even when given in very large doses.

Among other remedies which have received the sanction of good authority for the curing of this disease, are cubebs, copaiba, potassium chlorate, the sulpho-carbolates and sulphites of sodium and potassium, and the salicylates and the benzoates of potassium, sodium and ammonium. Indeed, there are few remedies of any potency in any disease which have not been tried for this affection and which have not, for a time at least, received more than merited praise.

When the disease extends to the larynx, non-depressing emetics are sometimes useful to dislodge the false membrane and the mild chloride of mercury in large and frequently repeated doses has seemed to me most beneficial in preventing its deposit. I have given calomel in such cases in doses equivalent to half a grain for each year of the child's age, and repeated every one or two hours according to the severity of the case, until its effects upon the bowels were noticeable. It is surprising how much of the remedy may be taken in such cases before its characteristic effect upon the stools occur. I have seen a child two or three years of age take 30 or 40 grains before the bowels moved. As soon as the effects of the remedy are noticed upon the stools, the dose should be diminished in size and frequency and as soon as the dyspnœa is relieved, the remedy should be withdrawn. Unfortunately, whatever remedies are employed, the false membrane will frequently extend to the glottis, as indicated by difficulty of breathing, blueness of lips and finger nails, and recession of the soft portions of the chest walls during inspiration, when these symptoms occur, no time should be lost in adopting operative measures, although a certain number of cases may be cured by mercurials or a small precentage might recover from the unaided efforts of nature.

It is not safe to wait for nature or the slow effect of medicine in these cases, for statistics have shown that about 95 per cent. will prove fatal when the larynx has become involved, unless operative measures are adopted and even with these only 25 or 30 per cent. are saved. One of two operations may be adopted, the one to be preferred depending somewhat upon the age of the child and its surroundings. Other things being equal, in a child under five years of age, I decidedly prefer intubation by O'Dwyer's method, though in older children it is not quite as satisfactory as tracheotomy. Even in quite large children intubation has been found useful, particularly when the graver operation will not be permitted. I would recommend that it be tried first in all cases, because of the ease and rapidity with which it can be performed, the avoidance of a wound liable to a secondary infection and the ready consent of parents, and finally, because it is no bar to the subsequent performance of tracheotomy, should this severe operation appear necessary.

I hope, gentlemen, that you will try intubation in these cases, and I believe that none of you will fail in successfully introducing the tubes. The confidence gained by two or three intubations will cause the physician to recommend the operation earlier, and thus protracted dyspnœa and the consequent pulmonary congestion and œdema will be prevented and many lives will be saved that would be lost if the operation were delayed until suffocation became imminent. There is only one accident which is likely to occur in the

performance of intubation, namely, the crowding downward of loose membrane before the tube; this in a few instances has caused speedy death. To relieve the difficulty all that is necessary is to at once withdraw the tube, when the loosened membrane will be drawn out with it or will be coughed out immediately afterwards; but in some instances this happy result is not obtained, and, therefore, it is well for a physician always to have a tracheotomy set at hand when about to perform intubation, so that the trachea may be opened at once if necessary. I have never found it necessary to resort to tracheotomy at such times, but have long felt it best to be prepared for any emergency that might arise. It is best before doing intubation to explain to the friends that there is a bare possibility that the child may die before it is completed, because of this accident. When tracheotomy for any reason becomes desirable, it should be done as soon as practicable after marked inspiratory recession of the chest walls indicates serious obstruction of the glottis.

36 Washington street.

PATHOLOGICAL ANATOMY OF EXOPHTHALMIC GOITRE.

Mendel (*Deutsche medicinische Wochenschrift,* February 4, 1892) after calling attention to the poverty of medical literature in cases of exophthalmic goitre with definite lesions, reports a case observed by himself, over a term of two years, which was a typical case of this disease. The patient died of cardiac paralysis. At the post-mortem there were no gross lesions observed, either in the brain, spinal cord, sympathetic or vagus. Careful microscopic examinations were made, however, of all these parts. The cortical substance of the brain, the different ganglia, the cerebellum and the vagus were entirely normal. Two changes were, however, noticed; first, a difference between the two restiform bodies; in a series of 1,210 sections of the medulla the left restiform body was seen to be atrophic; second, there was evident atrophy of some of the solitary bundles in the right restiform body. The author calls attention to numerous experiments upon lower animals, where symptoms of exophthalmic goitre have been caused by a destruction of restiform bodies.—*Univ. Med. Mag.*

FRACTURE OF THE LOWER JAW.

By A. O. STIMPSON, M. D.,
THOMPSON, PA.

On 1st March, 1888, I was called to go and see Henry J. Cleveland of our town who was reported as seriously injured about the face. On examining the case I found a contused bruise of the left side of the lower jaw, with a double fracture of lower jaw, so that the incisor and canine teeth were turned out upon the chin. The accident was caused by the man's face being compressed and bruised from the sliding of a load of hay in a rack from the wagon toward the hay mow in the barn while attempting to unload it.

The lines of fracture are indicated by the

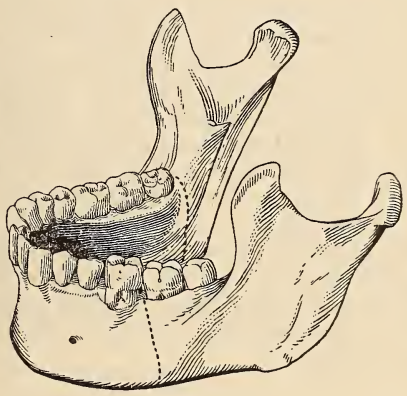

Fig. 1.

dotted lines (Fig. 1). After washing and bathing the face and jaw with an infusion of arnica-blows and cider vinegar (used warm), I applied a splint as follows: I took a piece of sole leather of the right length to extend around the lower jaw and split the splint like this (Fig. 2). I then sewed a bandage of the

Fig. 2.

appropriate length to each tail of my improvised splint, and after soaking the leather in warm water so as to mould it to the shape of the jaw, after padding it with

absorbent cotton, I fastened the lower segment of the splint over the vertex of the head and the upper one on the back of the neck in this way (Fig. 3). I extracted one of the in-

Fig. 3.

cisor teeth on left side to allow of nourishment being introduced by means of a rubber tube, and in twelve days' time the man was able to take nourishment in the ordinary way, but was not allowed to masticate any food until the expiration of thirty-two days. The patient made a good recovery, and to-day you can scarcely trace out the line of fracture, either in front or at the side of the jaw.

The point of interest in this case is that no sutures of wire or silk were used and still the bones were kept in close apposition by the simple confinement by the sole-leather splint.

HYDRAMNIOS AND PRESENTATION OF HEAD OF ANENCEPHALOUS MONSTER DIAGNOSED BEFORE BIRTH.

Pinzani (*Riv. di Obstet. e Gin.*, 1891, No. 24) attended a patient in whom, four days before her confinement, he diagnosed the presence of an anencephalous fœtus in an instructive manner. It was evident that the long axis of the fœtal body was vertical, and careful external examination indicated head presentation. On vaginal exploration, an irregular surface with numerous bony prominences was found presenting. Pressure on this surface set up convulsions in the fœtus; this phenomenon was observed on several occasions. Hence, face presentation was out of the question, and an anencephalous monster evidently present. The patient was delivered of a female anencephalous fœtus, which showed signs of life for a short time. Childbed was perfectly normal.—*Brit. Med. Jour.*

CLINICAL NOTES ON A CASE OF HYSTERIA IN A BOY EIGHT YEARS OF AGE.*

By SAMUEL AYRES, M. D.
PITTSBURG, PA.

The rather infrequent occurence, or perhaps recognition, of hysteria in young children, induces me to report the following interesting case:

William T., *æt* eight years, had good family history and previously good health. In the early part of December, 1891, while attending school, he became involved in a quarrel with four boys, who pitched upon and struck him about the face and head, there being left, however, no visible bruises or marks of injury. Immediately after returning home that evening he complained of severe headache, not specially localized. This continued without abatement for about two weeks, when the family physician, Dr. Wallace, of Ingram, was consulted. After treating the patient a few weeks there was still no improvement in the headaches, but otherwise the boy's general condition was not much impaired. He had not been allowed to attend school since the accident, but played about the house, had a fair appetite, bowels were regular, and there was no abnormal variation in temperature or pulse. But he was pale, and complained of almost constant headache. On the advice of Dr. Wallace, his eyes were during this time examined by Dr. Geo. W. Allyn, who found a low degree of astigmatism and prescribed glasses.

On the morning of January 17th, last, the boy had a fainting spell before breakfast and became very pale, weak and languid, complaining severely of the usual headache. At that date Dr. Wallace referred the patient to me, and the boy was brought to my office on the 18th of last January. A careful examination was made. Mentally the boy seemed clear, and gave prompt answers to all questions. His face was rather pale, the pupils widely dilated, contracting slightly to bright light. The tongue was extruded straight, and not much coated. The pulse about 80°, temperature normal. No abnormal

*Read before the Allegheny County Medical Society, May 10, 1892.

motor or sensory phenomena were noted. The optic discs were normal. The urine contained neither albumin nor sugar.

The headache, of which he only complained, was referred to the vertex and forehead. The nature of the case was not entirely clear to me. The cause was obviously connected with the injury to the head, as he had been perfectly well up to that time. I therefore inclined to the opinion that the case was one of simple neuralgia, or else a slight injury to the cerebral membrane, perhaps a localized patch of congestion in the frontal region.

On this theory I prescribed small doses of sodium iodide and sodium bromide; also one grain of ergotin three times daily, and blistered each mastoid process, In three or four days the boy was brought back to my office without any improvement in the headache. The same treatment was continued excepting that 1/8 grain of protiodide of mercury was substituted for the ergotin. A mild galvanic current was passed for a few minutes from forehead to occiput. The parents were directed to discontinue this treatment in two days if he were not better, and to give tablets containing three grains of antipyrin every three hours. The day following this I was summoned in great haste by the father to meet Dr. Wallace, the former stating that he thought his son was dying. It seems that the lad complained of being sleepy and tired, and sitting on a rocking chair apparently went to sleep, but at once exhibited some general convulsive movements, and became wildly incoherent. When Dr. Wallace and I arrived, the boy was in bed and appeared rather bright and talked rationally. His pulse was about 90°, temperature normal. He complained, as usual, of the headache. When questioned as to the spell he had just had, he seemed to remember nothing about it. Very soon he was seized with one of these paroxysms, consisting of symmetrical clonic spasms of the forearms and hands, the same spasmodic movements passing to the lower extremities, the whole attack lasting scarcely a minute. There was apparently no loss of consciousness; no frothing of mouth; no change in the color or expression of face. At another time there would be a rapid turning of the head from side to side, or contortions of the entire body, or opisthotonus, accompanied by profane utterances, or other incoherent outbursts, terrifying and shocking his parents. We withdrew the iodide, increased the bromide to 10 grains every three hours, and gave a little tr. of opium and aconite. Broths and other concentrated nourishment were given and accepted at frequent intervals. At our consultation the following day the boy was rather worse. The paroxysms, above described, had been more severe and frequent. The breathing at times had been irregular and jerky, diplopia had been observed. The head was occasionally retracted and bored into the pillow. The parents stated that he had been very "flighty"; that at times his eyes were glassy and upturned and that they thought in one of these spells he would die. He had taken nourishment and slept fairly well, though during sleep there was much muscular twitching and catching respiration. When we entered the room the boy greeted us, and smiled and talked intelligently. We soon got him out of bed and tried to have him walk. His gait was very unsteady and he settled well back on his heels, inclining to fall backwards. But with assistance he walked some.

Replacing him in bed and retiring from the room we slightly opened the door. In a few moments he had one of the paroxysms above described. Gliding in swiftly I pressed firmly on the supraorbital nerve. The boy immediately ceased his contortions, cried with pain, and said I had hurt him. We desired no further proof of the nature of the case, and the subsequent history confirmed the diagnosis. On appropriate treatment, of tonics, outdoor exercise, and the ignoring of his headache by the family, the boy gradually recovered, only once after having hysterical attack, which was promptly arrested by the same means.

The fact that the patient was a boy, that he was so young, and that the headaches seemed to be of traumatic origin, quite misled us for a short time, as to the real nature of the trouble.

I will not detain the society with any remarks on hysterical affections in young children. They do, of course, occur in children of either sex, much younger than this one, but are, I believe, comparatively rare in our country. In France, nursery hysteria is by no means uncommon.

THE TREATMENT OF CYSTS AND ABSCESSES BY PAPOID AND PEROXIDE OF HYDROGEN.

By O. A. HYDE, M. D.,
NEW YORK CITY.

The first case was one of sebaceous cyst at the calf of the leg, the cyst having existed for at least ten years, and until recently, given but little trouble. When I opened the sac, it was inflamed, partly broken down and about to open at the site of my incision. Its cavity contained about 16 to 20 grams of decomposed sebum and pus. I made but a small incision that the fluids might be better retained. The solution employed was as follows, viz:

℞ Papoid..... 15 to 20 grams.
Sodii Bicarb..... 5 to 10 grams.
Aquæ..... 100 c. c.

This injection was allowed to remain from one to eight hours, then pressed out of sac, and a strong solution of peroxide of hydrogen introduced to thoroughly clean the cavity. This was repeated once or twice daily. The patient was irregular in treatment of cyst, otherwise the result would have been obtained earlier. A few weeks of this treatment entirely removed the cyst wall, and satisfactorily cured the case.

The second case was one of perineal abscess, that owing to the carelessness of the patient had existed for several months, during which period it had been thoroughly injected daily with peroxide of hydrogen solution. The patient was unwilling to remain away from his business, and thus have the necessary rest for cure, and also was troubled with uric acid deposits and calculi in bladder. The abscess improved under above treatment, but would break down occasionally and discharge pus. Several times the urethral floor was perforated by the pus, and urine passed freely through the sinus. I injected a 15 per cent. solution of papoid, of the formula above given, allowing it to remain in the cavity about 10 to 15 minutes. The patient described the sensation at the time, as though many mosquitoes were stinging the sac walls. I cleansed the cavity with peroxide hydrogen solution as before. In a day or so, the abscess closed and remained so for ten days; it then had a slight discharge of pus, but an injection of peroxide hydrogen was followed by permanent closure of the sinus. This treatment was given three or four months ago.

The prompt arrest of this abscess from a single injection of an alkaline 15 per cent. solution of papoid, greatly surprised me. The cure cannot be attributed to peroxide or hydrogen, as this had been used for months with favorable, but not curative results; employed, after the papoid, it simply, or mainly oxidised the debris or digested pyogenic membrane, facilitating its removal.

Had I employed the papoid and been aided by rest to my patient, I am confident that I could have cured the case, probably several months earlier.

THE TREATMENT OF PERITYPHLITIS.

Dr. Vollert describes (*Deutsch. Med. Wochenschr.*, No. 33, 1891) the treatment pursued in this affection at the clinic of Nothnagle. In recent cases, leeches (about ten) are placed over the seat of inflammation. The leeches are supplemented by the ice-bladder and cold cloths. If the cold is inconvenient to the patient, then poultices are employed. If the resorption by the exudation is delayed, inunctions of green soap or iodoformized collodion, with tincture of iodine, equal parts, is applied to the part. The diet is, of course, regulated. Pain is controlled by morphine. After subsidence of the inflammation, during the period of convalescence, rectal injections are given, in case no spontaneous alvine evacuation occurs. The enemata may be aided by Carlsbad salts. In inveterate cases of peri- and paratyphlitis, where the exudation is not resorbed, massage and warm poultices are especially serviceable. An operation in perityphlitis is only indicated when an abscess is positively shown to exist. The cases most favorable for an operation are those where the exudation is circumscribed and encapsuled. It has been frequently observed, under proper treatment, that even large accumulations of pus have been resorbed. When peritonitis occurs as a complication, the prognosis is always more grave. When the vermiform process is perforated, it is best resected, unless it is attached to the neighboring intestines.—*Wiener Med. Presse.*

THE ARTIFICIAL FEEDING OF INFANTS.*

By CHARLES S. SHAW, M. D.,
PITTSBURG, PA.

The proportion of artificially fed infants to those suckled by the mother, or wet nurse, in large cities, is variously estimated to be from ten to twenty per cent. As these estimates are based solely upon individual observation they necessarily differ widely because of the various conditions of environment that determine the method of feeding. Broadly, it may be said, that in the higher social scale the infant is more likely to be deprived of its natural nourishment. My own experience would place the proportion of artificially fed infants at not less than ten per cent. This refers only to infants who are fed exclusively in this manner; the proportion would be much larger if it included those in whom, because of a deficiency in the quality or quantity of the mother's milk, some artificial adjuvant is necessary. The proper feeding of infants artificially is a subject that may well engage the attention of medical men, for it may be safely asserted that the number of children properly so fed is, unhappily, very small. It is needless to refer to the disasters that attend the bottle-fed baby; they are too familiar to demand anything more than a passing notice. The statement of Holt may be quoted, however, as a general index of infant mortality under these conditions. Of 1,943 cases of fatal diarrhœal disease, 97 per cent. were artificially fed.

With the maternal method of feeding constantly before us as a model, it would seem that a sufficient substitute ought not to be difficult to obtain, but in spite of the apparent simplicity of the problem it has not yet been entirely solved, and until very recently hardly any progress whatever has been made towards its solution. There is, however, a vast improvement in the artificial feeding of infants in the last two years; and the improvement is due, like most recent advances in medicine, to a recognition of the all-pervading influence of bacterial life. The investigations of the bacteriologist, which have so enlarged the power and scope of surgery, which promise so much in the treatment of disease, have also had a most salutary effect upon the subject under consideration.

In dealing with this question of artificial feeding, it is evident that we should endeavor to approximate the maternal and natural method as closely as possible, in the composition of the food, and the quantity, the frequency of feeding and the method of administration.

Practically, we have but one substitute for the mother's milk, that is the milk of the cow. Goat's milk, asses' milk and mare's milk have been suggested and recommended, but it is evident that their usefulness is very restricted. The legion of prepared foods in the market may be dismissed without notice. They are all defective in composition and at most can be used only as adjuvants to a diet whose basis must be milk. The milk at the command of the consumer in a large city is that which we must use. Of course it goes without saying, that the fresher and purer the milk the better, but with the modern method of treatment, the milk in the hands of the dealer is sufficient, so the care and the expense often futile too, with which the anxious parent sought out peculiar excellencies in the milk for the child are now largely removed. The endeavor is to make a food of this milk that will resemble the mother's milk as closely as possible.

The average of the analyses of human milk, taken from Rotch's article in the Cyclopædia of Diseases of Children is: water, 87-88 parts; solids, 12-13 parts. These solids are: fat, 4 parts; albuminoids, 1 part; milk sugar, 7 parts; ash, .2 parts. Cow's milk shows by the same authority, practically the same proportion of water and solids, the solids are: fat, 4 parts; albuminoids, 4 parts; milk sugar, 4 parts; ash, .7 parts. Here we see the same amount of fat in each, but the cow's milk contains four times as much albuminoids, a little more than one-half as much milk sugar and more than three times as much ash. Evidently if we dilute the cow's milk with water till the albuminoids are the same in each, we will have only one-fourth as much fat, a little more than half as much sugar, while the ash will be nearly the same. Then by the addition of fat and milk sugar in the proper quantity to the diluted cow's milk, we make a mixture very closely resembling the mother's

* Read before the Allegheny County Medical Society, May 10, 1892.

milk. But the cow's milk, as we find it in the market is acid, while woman's milk is invariably alkaline. To remedy this we add lime water to the mixture, and the result is a compound that seems to be almost identical, chemically, with human milk. For the preparation of 8 oz. of the mixture, as given by Rotch, take water, 3 oz.; cream, 2 oz.; milk, 1 oz.; lime water, one-fourth strength, 2 oz.; milk sugar, 3⅜ drams. One of the essential differences between cow's milk and woman's milk, that is removed by this dilution, is the character of the curd. Undiluted cow's milk coagulates in hard and large curds, while the curd in woman's milk is very light and fine. The dilution of cow's milk, with four parts of water, reduces the curd to about the same as that of woman's milk. The mixture resembles closely the old Meigs' mixture that was so popular in Philadelphia a generation ago. In composition, appearance, taste and reaction, it is almost a perfect imitation of human milk, but there is still a most important difference—the mother's milk is sterile; the mixture is not. It is the sterilization of the artificial food that is the great advance in modern infant feeding. The experience of the nursery long ago taught that boiling the milk made it "keep better," and rendered it more acceptable to the infant's stomach. Reason would suggest that raw milk is the most natural, and therefore the better food for the child; and Raudnitz has demonstrated that boiling the milk lessens its nutritive value, but in spite of these objections the boiled milk was preferred. The reason for this preference is that boiled milk is sterilized, and sterilization is of more importance than comparative nutritive value or digestibility. The reason for the well-merited popularity of condensed milk may be found in the same fact. Condensed milk, though a very imperfect food, chemically, is more or less sterile, and this compensates for all its short-comings. Now, if we sterilize the mixture above described, we have counterfeited the mother's milk in every essential particular, and have, if not the ideal food, at least a very satisfactory one, and the best at present attainable, This is done by heat. The most convenient way is by subjecting the mixture to a steam bath for 20 or 30 minutes, though any other method of thorough heating will answer. The only requisite is that the mixture shall be heated to a temperature of at least 212°, and kept at that heat for 20 minutes or more. The vessel containing the mixture may be placed in a water bath and heated, or a steam sterilizer may be improvised with the kitchen utensils known as a collander and a pot for boiling water. It is, however, better both for efficiency and convenience to use some apparatus designed for the purpose. Various forms of sterilizers are on the market, and they may be equally good, but my experience has been limited to that known as the Arnold Steam Sterilizer, with which you may be familiar. It consists of an evaporating pan surmounted by a steam chamber, which holds a rack containing a number of 7-oz. graduated bottles. It is made of tin and is inexpensive. In using this apparatus the child's food for the day is prepared when the milk arrives in the morning. When making the mixture the lime water should not be added until after heating. Otherwise the food will have a straw yellow color, and the taste will not be as pleasant, though the nutritive value and wholesomeness are not impaired. Sufficient of the mixture, without the lime-water, for each nursing is put into each bottle, and the whole sterilized by 30 minutes' steaming. The proper quantity of lime-water is then added to each bottle, the neck of each is stopped by a plug of clean cotton, and as required they are used. In this apparatus the sterilizing bottles are used as nursing bottles, and very excellent ones they make. The plug of cotton is removed, the rubber nipple adjusted, and the mixture heated to about 100° in warm water. Any food remaining in the bottle after the infant has satisfied its appetite, is thrown out. This use of the bottle is not only a great convenience, but it also removes all necessity for disturbing or handling the mixture after sterilizing, and renders subsequent contamination of the food improbable.

The quantity of this sterilized mixture to be given to the child at each feeding depends, of course, on the size and vigor of the infant, and its digestive capacity. Biedert's law is two-and-a-half ounces of the food to every pound weight of the child in 24 hours. During the first three months the babe may be fed every two hours during the night. This would make ten feedings in the twenty-four hours, and, allowing one-and-a-half or two ounces at each

feeding, would amount to a pint or a little more of the mixture. There is always more likelihood of over-feeding than of under feeding. As the child grows the quantity of the food should be increased and the intervals between the feeding lengthened. At six months the child may be taking four or four-and-a-half ounces of food at each feeding, and a total of two-and-a-half pints in the 24 hours.

If the sterilized bottle is not used in feeding the child, the best substitute is the ordinary nursing bottle, or a common prescription vial of four or six-ounce capacity. This bottle is surmounted by the common rubber nipple or teat. As found in the shops the perforations in this rubber nipple are frequently too minute, and should be enlarged. In the selection of the nipple cares hould be taken that it is neither too hard and unyielding, a common fault with those made of white rubber, nor so soft and flaccid that it will collapse, as some of the black rubber and red rubber ones do. The worst apparatus is probably that arrangement with the long rubber tube, so popular with lazy and ignorant nurses, and to be had at all drug stores. It is a device worthy of the invention of a Herod, and its sale should be prohibited.

NERVOUS AND MENTAL DISTURBANCES FOLLOWING THE EXTIRPATION OF BOTH TESTICLES.

M. Weiss (*Wein. Med. Press.*, 1890) reports the case of a man fifty-four years of age, in whom a series of grave nervous symptoms occurred, shortly after the removal of both testicles for tubercular disease. This condition manifested itself by great mental and physical restlessness, agitation, palpitation of the heart, gastric crises, profuse perspiration, melancholia, syncope, etc. The author noted the similarity of these symptoms to those observed in women at the menopause, or after the removal of the ovaries.

He ascribes these disturbances to the absence of the normal secretions from these glands, which from the experiments of Brown-Sequard seem to have a marked tonic effect upon the nerves. The removal of this stimulant, he believes, results in a general nervous depression, as in cases where other habitual stimulants are suddenly suspended.

Society Reports.

ALLEGHENY COUNTY MEDICAL SOCIETY.

Scientific Meeting, May 10th, 1892.

J. C. Lange, M. D., President, in the Chair.

CLINICAL NOTES ON A CASE OF HYSTERIA IN A BOY EIGHT YEARS OF AGE. By Dr. Samuel Ayres. (See page 18.)

Dr. Charles S. Shaw read a paper on Artificial Feeding of Infants. (See page 21)

DISCUSSION.

Dr. Green: I am satisfied that every physician who has been so unfortunate as to engage in the treatment of children brought up on these diets, has a task before him. I have in numerous cases resorted to almost any or every method that I could find, preparing different foods in different manners, and am sorry to announce in many instances utterly failed in the end, but I have been successful very often in the feeding of a child on artificial diet, and I feel free to state while I am not wedded to any particular food or any particular manner of preparing food, I believe the condensed milk is very good and possibly proves successful in a larger number of cases than any other single milk diet that is artificially applied or given. I agree with Dr. Davis; I think it is well to examine the cow as well as the baby and food. I think, without looking to all these factors in the case, we many times fail, and if we fail to find a sufficient quality of food, and if we fail to find proper digestion of the food given to the child, by examining the different points or factors in the case, we often can arrive at the preparation of a particular food for a particular case. I think Dr. Kœnig's remarks were well placed. I feel that many times it is not the food; it is the stomach.

Dr. Lange. There seems to be a little diversity in the argument. The title of Dr. Shaw's paper was infant feeding, and although that is very hard to consider without considering some of the diseases, still it seems the discussion of diseases of infancy has got the upper hand. No one will claim that any food will prevent cholera infantum, "summer complaint:" that

if we had an ideal food that summer complaint would be banished from the land. It would probably be banished no more than other diseases will be, even under the best sanitary arrangements. It seems to me every doctor ought to have a standard as to infant's food. Now it has been said that it has often happened that infants would be fed from one cow and then another cow and a third cow, nursed by one wet nurse, and two, and three and to the number of five, but it must be remembered the period at which the fifth nurse nursed the child is not the same as the first, second or third did. The conditions of the stomach play the most important part and not the nurse. It has happened to me in my time, to have three infants who, we became convinced, could take absolutely nothing into the stomach: they probably could not have taken the ideal food if we had had it. These three infants were deprived of all food and were only anointed, one for a period of three weeks, with almond oil, oil of sweet almond, and the infants received nothing into the stomach but a little water and recovered and grew strong under that treatment, afterwards taking the milk well, which formerly disagreed. Now, the point I desire to make is, food, even if it is the best, is not always acceptable to infants. Then, as I understand it, shipping the milk, skaking the milk, driving the milk in the sun and canning the milk, can do it no harm if it is sterilized. It is not the heat that spoils it, but the bacteria that are in it. So, if it it were sterilized, it might be shipped around the world and come back as good as it was. That is a strong argument for sterilization, but we should have a standard of the best infant's food, irrespective of differences that may exist between mothers and cows. The same differences generally exist in every piece of meat that we all eat. Further, it has been said that it would be beneficial to add a digestive ferment, as for instance, pepsin. Now, pepsin is getting to be old, and I think the majority of you will agree with me if you studied it as close as I have, that it is a substance which is entirely useless. I do not believe a physician ever got any result from it, unless he had used along with it the important factor, hydrochloric acid, and I can promise every gentleman, in cases of gastric disturbances, if he will use pepsin without hydrochloric acid, and then use the acid without pepsin, the last will bear much better fruit than the first.

Dr. Shaw: Mr. Chairman, my conception of this subject was an average one, not the proper artificial food for any particular infant, that demands any particular care, not a food for an infant of abnormally weak digestive ability, but for the average healthy infant, an average food, as has been suggested, a sort of standard. Now the statement has been made that there is a great change in the mother's milk at different periods from the time of the birth of the child, consequently a standard artifical food that does not also vary, falls short of perfection. It does probably fall short of perfection, but the fact is, there is no practical difference in the composition of the mother's milk from the time of the beginning of lactation until the end of it. There are constant trivial differences brought about by indigestion in the mother—fatigue, unusual emotions, etc. Any of these things will involve the character of the milk to a certain degree, but they will not often involve it sufficiently to make any difference to the child; and the woman who has weaned a child may take the position of wet nurse, and the chances are will nourish it better than any artificial food. The changes that take place in the cow's milk have been said to be more important chemically than bacteriologically. There can be no such distinctions made, for bacterial growths always produce chemical changes.

The fact that condensed milk has been in the hands of some gentlemen particularly good, is only an endorsement of sterilization. It is evident to my mind that sterilization is not properly understood by some gentlemen, and when "sterilized milk" acted as a poison it had not been properly sterilized. Sterilization means more than boiling the milk. It means making it sterile and keeping it sterile. The milk as it comes from the cow is sterile. It is absolutely impossible to keep it sterile for any length of time in the marketable article of milk. It becomes necessary to sterilize it, and that can only be done just before the feeding of the child.

It is a fact that some children will thrive on almost any food; a fortunate fact. I know of children that from a very early

age, two or three months, have been fed almost exclusively on boiled barley. It has been often said that infants would not digest starch, but sometimes they will, though it is evident that starch is not as good a food for children as milk. The probable reason for the digestion of starch in the absence of a proper amyloid digestive apparatus is the mucus of the stomach and the intestines. The suggestion of one gentleman as to the time of putting the lime water in the milk, I do not think it calls for any particular discussion. It is to my mind only a matter of convenience. It is only important that it be put in. Infant's food's on the market, in my experience, have not been satisfactory. Those of them that are used with most satisfaction are used with milk, and the milk that is added to them, and the boiling that is usually directed to be done when making the mixture, makes a good food, because it is sterilized milk. Some of them have elements of nutrition that are suitable to the digestive capacities of an infant, but many have not. I have had a very annoying but instructive experience recently in the Rosalia Foundling Asylum. We have had constantly in charge from fifty to sixty infants under ten months old. About one-half of these children were fed on bottled food. The opportunity was excellent for the trying of a great many artificial foods, and we tried carefully, and with the help of skilled nurses and asistants, almost all the foods in the market, and none of them were satisfactory. The sterilized milk as prepared by Dr. Rotch's formula certainly suited these children best. I am satisfied that where it fails in a healthy infant the cause will be that it is not properly prepared and sterilized.

THE SCARLATINAL BUBO.

Drs. Combemale and Lamy have found in a case of cervical adenitis, of scarlatinal origin, going on to suppuration, that the pus, while entering such micro-organisms as streptococci and staphylococci, is not virulent. The microbes appear dead, or are at least deprived of the power of reproduction on nutrient media. Their observations lead them to believe that these microbian agents act more through their toxines, which call forth an abundance of leucocytes.—*Bulletin Méd. du Nord*, January 8, 1892.

Selected Formulæ.

ACUTE CORYZA.

Dr. Hayem, in the *Union Médical*, recommends the following inhalation in recent cases of acute coryza:

℞ Acid. carbol. pur..... 5.0 grammes.
Ammon. liquid. ..... 5.0 "
Aquæ.....15 0 "
Alcohol.....15.0 "
M.

A few drops of the solution should be poured on blotting paper and inhaled. It will be found to act pleasantly and give relief in the majority of cases, while in some it acts as an abortive. The following snuff is also recommended:

℞ Bismuth subnitri.....6.00 grammes.
Benzoin pulv.....6.00 "
Acid boric, pul .....4.00 "
Menthol.....0.2 "
M.

Vaseline and subnitrate of bismuth in equal parts will be also found a valuable application.

AN ANTISEPTIC SOLUTION FOR VAGINAL INJECTIONS.

L'Union Médicale states in its issue for February 29, 1892, that the following is used by Sunar for the purpose of rendering the vagina antiseptic:

℞ Beta-naphthol, ... 5. iv.
Alcohol, ... 5 xxx. M
Sig.—Make into solution and add a teaspoonful to a quart of water which has previously been boiled and filtered.

This mixture is then given as a vaginal injection, cold or hot, as the case may require it.

TURPENTINE IN ICTERUS.

Dr. Carceau (*La Semaine Médicale*, No. 12, 1891; *Lo Sperimentale*, No. 23, 1891) has recently used the essential oil of turpentine in all forms of icterus with hemorrhages and albuminuria, as Weil's disease, bilious fever, hæmoglobinuric fever, as well as yellow fever. He administers it as follows:

℞ Ozonized oil of turpentine, gms. 10.
Liquid vaseline.....gms. 36.
Inject subcutaneously.

The same quantity may be given in capsules, of which some sixty may be taken within thirty-six hours, thus taking two or three every half hour. By this means he has been able to cure the most severe cases of icterus accompanied by great albuminuria and convulsions.

BRONCHITIS IN CHILDREN.

Dr. Hare gives the acute stages of bronchitis in children:

℞ Tr. aconiti.....gtt. xij.
Syr. ipecac. ..... f. ʒssj.
Liq. potassii citratii.....q. s. ad. f. ʒiij.
M. Sig.—One teaspoonful every three hours.

For the latter stages:

℞ Ammonii chloridi.....ʒj.
Ext. glycyrrhizæ fl.....f. ʒiv.
Aquæ dest.....q. s. ad. f. ʒiij.
M.—Sig.—One teaspoonful three times a day.

HEART PAINS.

The formula which Dr. Liegeois especially recommends is as follows:

℞ Tinct. piscidæ erythrinæ.....gm. 60.
Tinct. verat. virid.,
Ext. aconiti rad. alc.....āā. gm. 15.
S.: 30 drops morning and night.

INJECTION FOR GLEET.

℞ Hydrarg. bichlorid..... gr. ½.
Zinci sulph. carbolat..... ʒ ss.
Acid boric ..... ʒ jss.
Liq. hydrogen peroxid.... .....fʒ iv.
Aquæ destillat..... .....fʒ vj.
M Use injection in the morning and evening.

Dr. A. Hewson, *College and Clinical Record.*

BALANITES AND BALANO POSTHITIS.

During the stage of inflammation:

℞ Sodii boracis.....ʒv
Aquæ Bullientis.....ʒviij
M. ft. Lotio
Sig. Retract the prepuce and cleanse thoroughly with the lotion. While still wet apply.

℞ Bismuthii subnitratis

Sig. Dust plentifully over and around the glans and then pull the prepuce forward to its natural position and allow it to remain thus covered for twelve or twenty-four hours, when the treatment can be renewed if necessary, daily.

To prevent relapses wash the part two or three times a week with the borax lotion.

Julias A. Faison, M. D.
Mount Olive, N. C.

TREATMENT OF DIPHTHERIA IN PARIS.

The following treatment of diphtheria in children is much advocated at present. The room is steamed with a solution as follows:

Phenic acid ..... ʒ ij.
Solicylic acid ..... ʒ iv.
Benzoic acid..... ʒ jss.
Alcohol..... ʒ iv.

A tablespoonful is put into a quart of boiling water and renewed every three hours.

As a local application:

Camphor..... ʒ v.
Castor-oil..... ʒ iv.
Alcohol..... ʒ iij.
Phenic acid ..... ʒ j.
Tartaric acid..... ʒ i.

—*Medical Press.*

ARABIAN BALSAM.

A good formula for Arabian Balsam is as follows:

℞ Take of
Oleum gossypium..... 15 ounces.
Oleum origani..... 1 ounce.
Oleum terebinth..... 4 drams.
Mix.

S. W. Rogers.
Harwick, Mass.

OUABAINE.

J. Sailer (*Therap. Gaz.*, November and December, 1891), who has investigated the physiological action of ouabaine, has arrived at the following results:—1. General action: On dogs and animals capable of vomiting it acts as a powerful emetic; it excites defæcation, perhaps by paralysis of the sphincters; it is probably a diuretic, at least it always causes urination in animals to which it is administered; it does not affect body temperature. 2. On the circulation, ouabaine produces first a slowing of the heart from stimulation of the cardio-inhibitory mechanism, perhaps also from direct action on the heart muscle. At the same time there is a vasomotor spasm sufficient in most cases to overbalance the slowed heart rate, and to produce rise of blood pressure. Next, there occurs sudden and great increase in pulse rate from paralysis of the vagi, and still further rise in blood pressure, with continued vascular spasm. Lastly, the heart itself is paralyzed, and death ensues. 3. On respiration, the drug probably acts by stimulating the respiratory centre, but only to a slight extent; respiration generally continues for some time after the heart has ceased beating. 4. On the nervous system (*a*) the drug diminishes and finally abolishes reflex action by paralysis of peripheral sensory nerves and nerve trunks; (*b*) motor nerves seem to be only exceptionally paralyzed, unless the drug be applied direct to them; (*c*) on the central nervous system the drug appears to exert no action. 5. Muscles are paralyzed by a direct action of the drug on their tissue. 6. On the dog the drug acts as a very powerful local anæsthetic when applied to the cornea in weak solution, and this without causing any inflammation, in man, however, it has been stated to produce much irritation when thus applied.

THE

MEDICAL and SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

DIRECT COMMUNICATIONS TO

P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor.

(Professor of Physiology, University of Penna.)

BUSINESS OFFICES:

9 to 35 North Tenth Street, Cor. Filbert.

EDITORIAL OFFICE:

Southeast Cor. 36th and Woodland Ave.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00

REMITTANCES should be made payable to THE MEDICAL AND SURGICAL REPORTER, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

—o—

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates).... $1 00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt "**The Medical and Surgical Reporter**" and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts.....$1.50 each.
Bovine Points or Quills..... 1.00 a doz.
Humanized Crusts..... 1.00 small.
Humanized Crusts..... 2.00 large.
Guaranteed in every respect.

Leading Articles.

THE ANATOMY OF THE TONSILS, WITH REFERENCE TO THEIR SURGICAL TREATMENT.

Although we have but little knowledge of the physiology of the tonsils, we have practically to consider them as causes of many disturbances of function, as well as being the seat of acute and chronic inflammation. Their influence in the pathology of the naso-pharynx is especially great, and able observers have shown that many obscure troubles affecting these parts can often be traced to an abnormal condition of these organs. Consequently, it is important that we should have correct ideas of their anatomy, in order that we can intelligently treat them when they are the seat of disease.

The profession is indebted to Dr. Harrison Allen for a recent and very valuable paper upon this subject, which is entitled, "The Tonsils in Health and Disease," in which that able authority on diseases of the throat gives a more satisfactory account of the gross anatomy of the tonsil than is found in any of the standard text-books. The intent of his paper is best described in his own words (*Amer. Jour. Med. Sciences*, p 92, 1892.): "The object of this paper is to harmonize the descriptions of the normal tonsil with the accounts of its morbid conditions. It is an axiom in medicine that the best basis on which the clinical study of any organ can rest is on exact knowledge of its structure. I will endeavor to show that our conceptions of the tonsil are not in conformity with this axiom. Some of the descriptions of the tonsil have been drawn up from hypertrophied glands, some from atrophied glands, while the terms used by anatomical and clinical writers are often at variance with one another. I cannot recall any other structure in the body of which this can be said. This confusion does not arise from lack of

knowledge, for numbers of valuable papers have been written on the tonsil and its plan is understood. But the description of the mass is conventional and clinicians have not seen fit to depart from antiquated and often quite inaccurate methods of expression."

In the above quoted paragraph the author clearly indicates what is actually the case, when the various standard authorities upon anatomy are referred to, viz., that their descriptions of the structure of this clinically important organ vary very much from each other, and that, as a consequence, we do not possess clear ideas regarding the normal structure.

The fact is, according to Dr. Allen, there is considerable normal variation in the form of the tonsil, while its general morphological plan remains more or less constant, except in those cases in which it is completely masked by disease. The form of tonsils most frequently seen by him he describes as follows: "The variation which I have most frequently seen is a rounded or elliptical mass—of which the vertical is the largest diameter—placed in the tonsil space a little above the level of the tongue. The organ is slightly compressed from before backward, and consists for the most part of a pocket or crypt —whose walls are greatly thickened— directed downward. The anterior wall of the pocket is covered with mucous membrane which is every way similar to that lining the pharynx, along the side of which it sometimes extends as far as the tip of the epiglottis. Above the mouth of the pocket lies a mass which constitutes the 'tonsil' of common language. This alone is cryptose." From this it will be seen that the almond-shaped body, commonly described as the tonsil, is really but a portion of the tonsil. In addition to the foregoing, Dr. Allen describes a "second smaller, somewhat nodular body which is quite distinct from the foregoing," situated higher up and slightly back of the palato-pharyngeal fold, which he terms the "velar tonsil." The middle portion of the tonsil, situated above the main pocket as described above is very commonly, according to Allen, channelled by "numerous communicating passages," especially seen in the tonsils of children and which often run deeply into the gland. Haller, Luschka and Asverus also describe these slits and fissures, which in the adult are obliterated by hypertrophy of the connective tissue elements of the gland, with atrophy of the lymphatic follicles, so that the organ is reduced to hard nodular masses, which bear no resemblance to the original structure of the gland.

We need not dwell further upon the anatomical peculiarities which are so ably presented by Dr. Allen, and will refer the reader to the original paper.

Not only must we have a clear understanding of the anatomy of the tonsil to successfully treat the organ when it is in a diseased condition, but also the changes which age effects in its appearance. The tonsils are largest in childhood and atrophy after the age of 25 years. Their development, Dr. Allen thinks, has some relation to the "rate of dental development, and the small size of the jaw." Regarding the enlarged tonsils of children, the same authority lays down the following clinical rule for determining whether the enlargement is physiological or pathological: "No matter how large the tonsil may become, it need not constitute a clinical state unless respiration is impeded. If the child has nasal respiration, a natural form of chest, and roof of the mouth and the teeth regular, the tonsils are in a physiological condition; but if there is snoring respiration, irregular teeth, the habit of mouth breathing established, a high, narrow palatal arch being present, and the child be pigeon-breasted, then the enlarged tonsil may be said to constitute a clinical condition."

When it is necessary to excise the tonsil

there is considerable difference in opinion and of practice about the procedure; some advocate the removal of but a superficial layer of the organ, while others claim that the best results follow when the whole tonsil is removed. The weight of evidence is decidedly in favor of partial exsection, because it is a more simple procedure, the parts heal more rapidly, and it is not likely to be followed by such serious hæmorrhage as sometimes attends the extirpation of the whole organ.

The dangers of excision of the tonsil for acute abscess should not be forgotten, and in view of the frequent occurrence of fatal or alarming hæmorrhage in such cases, it should be carefully performed. Allen advises that the tip of the left fore-finger be inserted behind the tonsil, between it and the pharyngeal wall, and that the point of the knife be directed towards it. Good light and a firm position of the head are requisites.

EFFECT OF MERCURY ON THE BLOOD OF SYPHILITICS.

Bieganski (*Archiv für Dermatologie und Syphilis*, 24, Jahrgang, 1892), from a research upon the alteration of the blood incident to syphilitic infection, concludes that the syphilitic poison has no effect in altering the number of blood-corpuscles; that it increases the number of white blood-corpuscles, particularly the small mononuclear lymphocytes. At the same time the number of the polynuclear white blood-corpuscles diminishes. The hæmoglobin of the blood is distinctly lessened. On the administration of mercury, the blood count is subject to marked changes. These, however, are dependent upon the greater or lesser thickness of the blood, and are not due to any change or alternation in the nourishment of the patient. Murcury lessens the number of white-corpuscles, and renders the relation between the white and red almost normal. It is particularly the mononuclear white corpuscles which are diminished in number, the polynuclear cells again becoming more numerous. The quantity of hæmoglobin is distinctly increased by the administration of mercury.

Book Reviews.

A TEXT-BOOK OF THE PRACTISE OF MEDICINE FOR THE USE OF STUDENTS AND PRACTITIONERS. By R. C. M. Page, M. D. Author of "A Chart of Physical Signs of Diseases of the Chest," "A Handbook of Physical Diagnosis of Diseases of the Organs of Respiration and Heart;" Professor of General Medicine and Diseases of the Chest in the New York Polyclinic, etc. 8vo, 578 pp New York: William Wood & Co. Price, $4.00.

A careful perusal of this admirably concise treatise convinces us that it will be found a useful book for those for whom it was written. In these days of rapid progress in medicine, with the wonderful advances which have been made in the methods of clinical instruction, it is most desirable that the students who go to the great medical centres especially for bedside instruction should possess some reliable medium of information to which they can refer quickly for any needed points—this is the motive which prompted the author to compile the present volume; and it may truthfully be added, is clearly shown in the pages of the book itself. Brevity, conciseness, and clearness of expression characterize it throughout, while the style and arrangement have not been sacrificed in order to attain these results.

The initial chapter upon the normal conditions of the chest, followed by a digest of the diseases of the heart and blood-vessels, is a model of lucidness, and presents the essential facts involved in a consideration of them, and very little more. In the ætiology and pathology of aneurisms we notice the failure to mention the mycotic variety which Eppinger has so well described, and seen by Osler. Another important omission occurs in the space devoted to chorea, in which only the ordinary chorea of childhood is described without mention being made of the adult, hereditary and senile varieties of the disease. In a work of this kind, however, it is chiefly important that the main facts concerning disease should be untrammelled by too frequent reference to unusual or rare conditions, and probably many omissions which occur throughout the book have been intentional, and, in justice, it must be said that but few of them are important.

The chapter on dysentery would have been more satisfactory if the amœbic

variety had received attention, and the connection between this form and liver abscess noted. This condition has of late years received considerable study in certain quarters and is certainly deserving of mention in any work on the practise of medicine.

The author differs from many in advising the use of quinine vigorously for "the first week or two" of typho-malarial fever, for according to the investigations of our Southern physicians living along the Mississippi River we know that a few maximum doses given at the very beginning of the disease are just as efficacious, and that the further use of this drug is sometimes positively harmful.

One of the best portions of the volume is that devoted to the treatment of disease. In that connection with each affection the treatment is carefully reviewed, and many prescriptions of well-known value have been added with the idea that they will be of service to the young physician.

In general terms we think that the author has been successful in condensing in one small and elegantly bound volume the best part of our knowledge of practical medicine, and that his object "to facilitate clinical instruction and enable both physician and student to obtain, in brief, the most practical as well as scientific view of various subjects treated of in a work on medicine" has been attained.

CANCER AND ITS TREATMENT. By Daniel Lewis, A. M., M, D., Ph D., Surgeon to the New York Skin and Cancer Hospital, etc., Detroit, Mich.: Geo. S. Davis,

In this new volume of the Physician's Leisure Hour Series the author has added a most instructive little book. Within the limits of 123 pages he has grouped the main facts concerning the ætiology, pathology, symptomatology, prognosis, and treatment of the different forms of cancer. He does not increase the difficulties attending a comprehensive study of this affection by the use of many terms, and broadly includes under the term cancer all malignant neoplasms. The author has also made use of cases seen at the Skin and Cancer Hospital for purposes of illustration, as well as cases from his private practise.

The opening chapter refers to the medicinal agents which have proven of some value. Among these he mentions Chian turpentine, chloride of aniline and pyoktanin. The chapter devoted to the discussion of the development of cancer from non-malignant affections is interesting. In other chapters cancer of special regions is dealt with, and some interesting statistics are given. Special mention should be made of the part devoted to treatment, since it is wholly modern, well written and in accord with the best principles clinical experience has taught us. The brochure is an exceedingly creditable addition to the Leisure Hour Series.

Periscope.

THERAPEUTICS.

DIURETIN IN INFANTILE PRACTICE.

According to the observations of Dr. R. Demme, Professor of Pædiatrics to the Faculty of Medicine of Berns, diuretin may be administered in the daily dose of .50 to 1.50 grammes (7½ to 22 grains) to children of from two to five years old, and in daily doses of 22 to 45 grains in children of six to ten years. In infants less than a year old the drug is contra-indicated, as it easily provokes gastro-intestinal irritation in these young patients.

Care should be taken in prescribing diuretin, as it is liable to be decomposed by certain substances. M. Demme recommends the following:

℞ Diuretin.....gr. xxij
Distilled water.....M iij
Brandy.....gtt. x
Sugar.....grs. xl
M. Sig. To be taken in the course of the 24 hours in doses of one tablespoonful.

Dr. Demme's observations have convinced him that diuretin is a good diuretic for children, exempt for the most part of all unpleasant influence, and probably acting on the renal epithelium.

Under the influence of diuretin, the dropsy of scarlatinal nephritis disappeared more quickly than by the action of any other medicament. It suppresses very rapidly the anasarca and serous effusions in cases of mitral disease, when the compensation has been previously established by means of digitalis.

The diuretin was generally well supported and it had no cumulative action. However, in one case of generalized dropsy in a child of ten years, suffering from amyloid degeneration of the liver, spleen and

kidney, Dr. Demme has seen a morbilliform eruption with abundant diarrhœa, after the injection of 90 grains of diuretin in the space of four days.—*La Semaine Médicale*, Feb. 24, 1892.

PENTAL AS AN ANÆSTHETIC.

Brener, in a communication to the Royal Medical Society of Vienna, reports having used pental as an anæsthetic 150 times in his dental practice. Loss of sensation is produced before complete loss of consciousness. Usually the patient recovers quickly and easily. The effect is produced generally in one or two minutes, and requires ten to fifty grammes. According to Rogner in the *Wien. Med. Pr.*, 1891, and Hollander in *Nouv. Rem.*, 1891, the loss of sensation lasts about four minutes, and towards the end of the seventh minute passes away. There is no vomiting or other troublesome symptom during the inhalation, nor does headache or sickness occur afterward. The loss of consciousness comes on during the first few minutes with complete loss of voluntary movement. Rogner considers it the best antiseptic to use in minor surgery. In spite, however, of these favorable reports, Brener himself had a serious accident. A girl who required extraction of a tooth was placed under the effect of pental. She had only taken four grammes when alarming symptoms arose—syncope, apnœa, loss of pulse, and dilatation of the pupil. It was necessary to resort to artificial respiration to restore consciousness. This fact, as Basch and Dittel observe, proves that new anæsthetics, and especially those producing rapid narcosis, require great care in their employment.—*Lancet.*

LA GRIPPE.

Epidemic Influenza, according to Dr. C. F. Taylor, *Medical Standard*, spends its force upon the central nervous system—especially the spinal cord. The local manifestations are due to interference with its functions which produces the frontal headache, nasal pharyngeal, laryngeal and pulmonary congestion, cardiac irritability, myalgia, enteralgia and intestinal catarrh, priapism with erotic excitement and temporary paraplegia. Erotic excitement constitutes a well-marked symptom in the earlier period of the attack in a considerable portion of cases. The remedies in this disease are ammonium salts and camphor. By the intelligent use of these, with other indicated treatment, the cure is generally complete, and complications and sequelæ are not likely to occur. The new antipyretics should generally be avoided, except in very robust subjects and in the first few hours of the malady. The first remedy usually indicated is ammonium bromide, as long as there is much acute pain. The next most important is ammonium salicylate if there be fever alternating with chilly and sweating stages. If there be torpidity of the liver, the chloride should be used. If the kidneys require especial attention, the benzoate. If the patient cannot be seen often, he suggests the following, which he has used with satisfaction:

℞ Acid salicylici.....5 ii
Ammonii carbonatis, q. s. ad neutr.,
Ammonii bromidi.....5 ii
Glycerini.....5 xii
Ammonii chloridi.....5 ii
Ammonii benzoatis.....5 ii
Lip. ammon. acet.....5 xvi
Aq. menth. pip. q. s.....5 xlviii
M. S.—One tablespoonful in hot milk or water every two hours, until relieved, then reduce the dose gradually to a teaspoonful, no dose to be taken in less than two hours after eating. Should be made fresh when needed.

This may be beneficially alternated with a good camphor mixture. The heavily loaded tongue is well met with sodium sulphite. Rest should should be absolute and complete, both physical and mental. The busy man who keeps at his work as long as he can stand, then goes to bed to have his correspondence read to him, and to dictate replies is virtually committing suicide. As between rest and no medicine, and medicine and no rest, the influenza patient had far better take the former.

ACTION OF PARAFFINIC NITRITES ON BLOOD PRESSURE.

Professors Cash and Dunstan have reported to the Royal Society on this subject, their knowledge being derived from experiments on cats and rabbits. It was found that the well-known effect of a fall in blood-pressure produced by amyl nitrite is due to the direct action of the drug on the vascular walls causing the vessels to dilate, and not to its action on the vasomotor centre. The experiments which the professor made were of two kinds. In the first the head was cut off from the circulation, and amyl nitrite still gave rise to as great a fall of pressure as when the head

was included in the circulation. In the second series the drug was injected into the carotid artery, but prevented from reaching the general circulation by appropriate ligatures. The fall of pressure did not occur until these ligatures or clamps were removed. Experiments were also made on man with a view to ascertaining the order of activity for various nitrites when inhaled, and the result was the following order: (1) alpha-amyl; (2) beta-amyl; (3) isobutyl; (4) secondary butyl; (5) primary butyl; (6) secondary butyl; (7) primary propyl; (8) ethyl; and (9) methyl. All the nitrites produce a fall of blood-pressure and an accompanying acceleration of the pulse; the latter is not so marked after intravascular injection as after inhalation, and is also less marked in cats than in men. The respiration is affected temporarily during inhalation in various degrees by the different nitrites, and permanently by repeated administration of the same or different nitrites.

ON THE ACTION AND USE OF TINCTURE OF CALUMBA.

Nearly 130 years ago, Dr. Percival of Manchester ("Essays, Medical and Experimental," Vol. II.), drew attention to the value of calumba root in diarrhœa, and recorded five cases, showing its efficacy. He pointed out that the tincture was the strongest preparation, and by experiments on himself showed that it did not influence the circulation.

Schultz (*Thérap Monat.*, Feb., '92) publishes a series of observations on the use of calumba in health and disease, which do little more than confirm the conclusions arrived at by Percival. He notes one or two points of practical interest. Out of the five healthy people to whom he gave a preparation made by extracting one part of the root with ten of alcohol, he found that in one, daily doses continued for a week, and gradually increased from 25 minims to a drachm, were followed by stomach catarrh and a slightly relaxed condition of the bowels. Eventually there was extreme repugnance to the medicine. In a second case, the action of the bowels became very slightly incresaed by large doses of the tincture. In none was the circulation affected; the other three were not influenced at all by full daily doses. The cases seem to indicate that in some even tincture of calumba may slightly disturb the bowels if continued long in full doses.

Schultz records 14 cases in which tincture of calumba seems to have a distinct effect in checking diarrhœa and regulating the action of the bowels. Even in the diarrhœa of phthisis he found it successful. He gave it in doses of from 40 minims to 3 drachms usually once, but sometimes twice daily.

TREATMENT OF SORE THROAT.

It is now generally admitted and agreed that in diphtheria some form of antiseptic or at least aseptic treatment should be used, but for the simpler forms of throat inflammation, and the catarrhal as well as tonsillar troubles, which are supposed to be caused by cold, the treatment remains for certain doctors what it was—that is, chlorate of potassium or other gargles of an emollient or astringent nature—and yet the simple fact that these troubles are frequently seen in the same family, and at the same time as diphtheritic diseases, would seem to indicate a common origin. The infectious nature of tonsillitis and other simple forms of throat and bronchial disease or inflammation seems likely, and once this is suspected, if not proved, it should lead to trying antiseptic methods instead of the old astringents. The following is a formula much used in France:

℞ Acid. carbol., cryst.
Camphor,.....āā gr. xv
Glycerini,
Aquæ destill.,.....āā f ʒii

This is painted on the inflamed part three times a day. It will be found to have a mechanical action as well as an antiseptic one.—*Archives of Pediatrics*, December, 1891.

TREATMENT OF BUBOES BY INJECTION OF IODOFORMIZED VASELINE.

Dr. Le Jollec (*La Semaine Médicale*, No. 55, 1891), a physician in the French navy, has treated several cases of buboes with success by the injection of a 5 to 10 per cent. solution of iodoformized vaseline into the bubo.

TO REMOVE ANILIN STAINS FROM THE SKIN.

Unna recommends washing first with a five per cent. solution of salt in water, then with the same strength of hydrogen peroxide, and finally with alcohol.

MEDICINE.

THE DIAGNOSIS AND PROGNOSIS OF SYPHILITIC DISEASE OF THE BRAIN.

Dr. Otto Harmsen has been induced by the scarcity of information relating to syphilitic disease of the brain to publish particulars of nine such cases, which had remained under observation for a year or more in the Berlin clinic for nervous diseases. The *Archiv. f. Dermat. u. Syph.*, which publishes the account, points out that the meagre statistics of this affection have often been complained of, more especially by Naunyn. The chief symptoms in most instances were headache, vomiting, vertigo, facial paralysis, aphasia, and hemiplegia. In one case polydipsia and polyuria appeared some years after the primary infection, and serious cerebral symptoms quickly followed. In another case the nervous symptoms appeared as early as two years after the initial sore. Nearly all the cases were cured by energetic anti-syphilitic treatment, this being most marked in a patient never before treated with mercury. It should be mentioned that in many instances a temporary disturbance of the reaction of the pupil was the first and only indication of cerebral mischief, as has been pointed out by Oppenheim.

ESSENTIAL PAROXYSMAL TACHYCARDIA.

Dr. J. W. Brannan, in a paper upon this subject, refers to that form of tachycardia in which a very great exhilaration of the pulse, occurring in paroxysms, was the cardinal symptom. The paroxysm might last a few minutes, or it might extend, without interruption, over a period of several weeks. In the intervals between the attacks the heart-beat should be normal, both in force and in frequency, and the individual seemed to be in perfect health. There was no history of rheumatism, nor were any valvular murmurs detected. In 4 cases in which an autopsy was performed no anomaly was found. Dr. Brannan has collected only 27 cases of this rare disease. The attacks are characterized by extreme rapidity of the heart's action, which may attain 250 or even 300 pulsations a minute. It is very much like that produced by section of the pneumogastrics in animals. The pulse is usually regular, often not perceptible at the wrist, but to be found in the carotids and femorals. The attacks occur suddenly, as a rule, and at other times they follow some strong mental emotion or physical fatigue or effort. The face is usually very pale throughout the paroxysm, the pupils are normal. There may be moderate dyspnœa. Anorexia and constipation are present with almost complete insomnia. The subjective sensations are variable, and include epigastic oppression, pain at the precordia and numbness of the left arm or general chilliness. The attack ends sa abruptly as it began; the pulse dropping suddenly from 200 or more to 72 beats per minute: There is extreme cardiac distension as shown by the area of dullness. In discussing the ætiology of the disease, Bouveret has drawn attention to the entire absence of hysteria, or neurosthenia in the cases collected by him, and there was no hereditary neurotic tendency. Of the 25 cases in which the sex was noted, 11 were in males and 14 in females. Over-fatigue, either mental or physical, seems to be the chief cause of the affection.

PRECOCIOUS HEREDITARY CEREBRAL SYPHILIS.

Dr. D'Astros (*Journal de Médicine*, Jan. 2, 1892) in a communication to the Association for the Advancement of the Sciences, spoke on the cerebral localizations in the new-born, to which Fournier has already called attention. These cerebral manifestations present themselves under various aspects: syphilitic meningitis (rare and ill defined); syphilitic arteritis of the arteries of the brain (quite frequent); gummata (rare and often during the second infancy); syphilitic ependymatis or ventricular syphilis, of which latter the author has observed two instances. The onset was quite precocious (one month after birth), and death took place in less than a month. At the autopsy (an acute ventricular hydrocephalus was found with embryonal infiltration in the ependyma and the striated bodies. The functional importance of the corpora striata for the reflex life of the infant is perhaps the cause of this localization. The cerebral gummata and syphilitic cerebral meningitis and arteritis are relatively late lesions, especially the first two; syphilitis ependymatis is the most precocious form and the most characteristic of hered-

itary cerebral syphilis. Its evolution appears to bear a relation to the degree of infectiousness of the syphilis. It is made manifest by a variety of nervous symptoms, convulsions, contractures, tremblings, strabismus, and especially by acute hydrocephalus of rapid development which is characteristic.

DOUBLE CONGENITAL ENTROPION.

Guibert (*Arch d'Ophtal.*, February, 1892) reports the case of a female child, aged 3, with complete entropion of the lower eyelids, the free border with the lashes being entirely hidden; in consequence of the infolding the lids appeared thickened. This condition had been noticed by the mother eight days after birth. The eyes had not suffered from the abnormal position of the cilia, the corneæ were clear, and there was no conjunctival irritation. The operative procedure adopted consisted in cauterzing along the skin surface two millimetres from the ciliary margin of the lid, and penetrating all the tissues down to, but exclusive of, the conjunctiva. The result was quite satisfactory and six months later there was no return of the entropion. A point of interest noted by the author is, that when applying the cautery to the lids, no structure was met with representing the tarsal cartilage (so-called). The absence of this constituent of the lid was looked upon by Panas as the probable explanation of congenital entropion, and Guibert thinks it will explain the condition in his patient. There were no other discoverable congenital defects in his case, and no family history of such.—*Brit. Med. Jour.*

THE SPECIFIC GRAVITY OF THE BLOOD.

A fair amount of literature is extant upon the subject of the specific gravity of the blood, and among those who have contributed thereto may be mentioned Schmeltz, Landois, Lloyd Jones, Roy, and lastly, Peiper, the latter having recently recorded some observations to which reference may here be made. The specific gravity of the blood in healthy human beings varies but slightly—1045 to 1046—with an average which is somewhat higher for men (1055) than for women (1053) or children (boys 1052, girls 1050). In disease the variations may be relatively considerable, that is, from 1055 to 1068. In nephritis, chlorosis, and anæmia, also in maladies associated with much wasting, such as phthisis and carcinoma, the specific gravity is lowered, but in febrile diseases, and in conditions causing marked cyanosis, it is raised. The blood of birds is apparently heavier (1059 to 1075) than in man, while that of frogs is lighter (1034 to 1053). It is evident, however, that not much is to be gained by the estimation of the specific gravity of the blood in disease, as far as diagnostic or therapeutic purposes are concerned. According to the author, "the specific gravity varies considerably in different persons, so much so, that a specific gravity which is normal for one may be a sign of disease in another." Under these circumstances it would scarcely be possible in any given case to say whether an apparently abnormal record was pathological, or the usual physical condition of the patient's blood.—*Med. Press.*

RECURRENT ERYSIPELAS.

Critzman (*Arch. gén.de Méd.*, January, 1892) says that erysipelas is distinguished from other cutaneous infections by its property of extending superficially, and hardly ever into the deep and subjacent layers of the integument. It is caused by the streptococcus erysipelatis. This micro-organism is, perhaps, identical with the S. pyogenes, but the suppuration produced by the latter cannot be identified with the serous inflammation produced by the former. It is disputed whether phlegmonous erysipelas (a complex affection) is due to the exalted virulence of the S. erysipelatis, or is an expression of a secondary infection. Erysipelas is very rarely phlegmonous from the outset, and suppuration is really a complication. The type of recurrent erysipelas is seen in the catamenial form. It may occur as often as ten, twenty and more times. Repeated attacks give immunity against symptoms, but not against the disease. Critzman relates a case occurring in a woman, aged 35, suffering from uterine fibroid. She had the first attack of facial erysipelas at 30, since when she said she had an attack nearly every month. The one observed by him began with shivering. A piece of skin was excised by permission of the patient. The cultivation and inoculation experiments were successful in demonstrating the micro-organism. In sections from the skin the

disease was made out to be a dermato-lymph-angitis, and the streptococci occupied the lymph spaces and vessels. In some of the infective diseases, as enteric fever, syphilis, variola, a second attack hardly ever occurs, but in others recurrence does happen, only to name ordinary tonsillitis. Two conditions only are necessary for recurrence: (1) presence of the micro-organism; and (2) a suitable soil for renewed growth. In recurrent erysipelas the streptococcus exists, as is shown above. After an attack it loses its virulence for a time, but under influences not yet understood this virulence may return, and with it the recurrence.—*Brit. Med. Jour.*

NORMAL TEMPERATURE OF THE AGED.

Kelynack (Manchester) publishes in the *Medical Chronicle* (vol. xv., 1892, No. 5) the results of observations on the temperature of healthy old persons (eighty-two, eighty-three, and eighty-nine years of age), which tend to show (1)that the normal senile temperature, as registered both in the rectum and axilla, is very distinctly below that of healthy children and adults. 2. That the rectal or internal temperature in old age is almost always higher than the axillary, but varying from 0.2° to 1° F.

SURGERY.

TREATMENT OF POST-OPERATIVE INTESTINAL OBSTRUCTION.

Lucas-Championnière (*Rev. de Chir.*, March, 1892) reports five cases in which it was found necessary to perform laparotomy for the relief of internal strangulation following operation on the viscera of the abdomen. In the first of these cases the symptoms of obstruction were presented on the eighth day after ovariotomy, and were found to be caused by old adhesions of the intestine to a mass of the omentum. The primary operation in three cases was for the radical cure of hernia, and in the fifth case for strangulated hernia. The post-operative obstruction was due in three instances to adhesions, and in one to the pressure of a large intra-peritoneal effusion of blood. All these patients made good recoveries after the second operation. Mention is made of a case of fatal obstruction after an operation for the radical cure of hernia, in which, after death, a loop of intestine was found to have been strangulated by a peritoneal band. In cases of this kind it is often difficult to determine whether the patient be suffering from actual strangulation or from simple obstruction of the intestine. If it be clear that the bad symptoms following operation are due to mere obstruction, purgatives, the author holds, ought to be administered. It is not a rare occurrence for laparotomy to be followed by intestinal paralysis with fæcal retention, the paralysis giving rise also to symptoms of occlusion with stercoraceous vomiting. With the view of preventing this bad result, the author makes it a general rule to administer a purgative two or three hours after the performance of laparotomy, thus following, and, indeed, carrying out to a further extent the practice advocated by Lawson Tait. Since he has adopted this line of treatment he has not observed the rise of temperature and the symptoms of gastric disturbance which so frequently result when the patient is subjected to the influence of opium.—*Brit. Med. Jour.*

CARCINOMA OF THE CARDIAC END OF THE STOMACH.

King (*Canadian Practitioner*, Feb. 12, 1892) reports a case, which occurred in a woman, 77 years of age, resembles those just above referred to, in its latency. The patient was a woman who had been admitted to a house, not on account of illness, but to provide her with a comfortable home. Her symptoms were few, and of no special moment; her appetite was fair, and she never vomited. Two weeks before death, however, a severe coffee-ground hæmorrhage from the bowel occurred, and two slight attacks followed in the next ten days, and three days prior to death another. This was regarded as proceeding from the bowel, and so treated; but she died on the third day after. The stomach was fouud to be the seat of carcinoma in the lesser curvature at its cardiac end, where there was a cup-shaped ulcer, the size of a Mexican dollar, with sharp, clear cut edges. There was no involvement of the œsophagus whatever. Large numbers of secondary deposits were found in the liver. Fagge denies the existence of cancer of the cardiac end of the stomach. He thinks that all the cases begin in the œsophagus and spread thence to the stomach; but in this case there can, in King's opinion, be no doubt it was primary. The entire ab-

sence of symptoms, in a case which was evidently of long duration, the situation of the cancer, and the fact that the immediate cause of death was hæmorrhage, all tend to make this case worthy of notice.

ULCER AND CANCER OF THE STOMACH.

Dr. E. Kollmar, of the Medical Klinik of Tübingen, has an instructive paper in the *Berl. Klin. Wochensch.* on the Differential Diagnosis of Ulcer and Cancer of the Stomach. The cases related by Dr. Kollmar show that neither cachexia, nor even a palpable tumor in the epigastrium is sufficient to render the diagnosis certain. Liebermeister placed the greatest reliance on the duration of the disease, and the author is at one with him on that point. If any gastric disturbance persists for years, if there has been vomiting of blood for a great length of time, the case is probably one of ulcer. Cases have been observed in which a cancer has developed in the cicatrix of an old ulcer, but the author considers them so rare that they may be ignored. In one case a tumor was felt, and the history showed illness of thirteen years' duration, and cancer was diagnosed. The abduction, however, revealed an ulcer that had led to attachment to the pancreas, and this formed the tumor in the epigastrium. The second case was that of a woman with a twenty-three years' history of gastric mischief. Here, in spite of cachexia, a palpable tumor, and absence of hydrochloric acid reaction, a diagnosis of ulcer was given, and the patient in fact recovered. In another case in which advanced anæmia with cachexia was present, the long duration of the illness led to a diagnosis of ulcer, which was verified at the post-mortem examination.

OBSTETRICS.

THE TREATMENT OF ASPHYXIA IN THE NEWBORN.

Forest (*Medical Record,* April 9, 1892) describes a method for resuscitating asphyxiated infants as follows: He places the child on its face, its head down, and expels fluids from the mouth by pressure upon the back; the child is then put in a pail or tub of hot water in a sitting posture, supported by one of the operator's hands across its back, its head bent backward. The physician grasps the child's hands with his other hand, carries them upward until the child is suspended by the arms, leans forward himself and blows air into the child's mouth; the infant's arms are then lowered, its body doubled forward, and its thorax pressed between the hands of the physician. Air is thus expelled. Especial advantage is claimed for this method from the fact that the hot water maintains capillary circulation, and tends to assist in promoting the action of heart.—*Amer. Jour. Med. Si.*

CÆSAREAN SECTION IN EXTREMIS AND AFTER DEATH.

Winckel (*Aerztliche Rundschau,* No. 5, 1892) discusses this question, which appears to have been taken into consideration by political and legislative authorities in Bavaria. These authorities have endeavored to ascertain if it be justifiable to enforce upon practitioners the performance of Cæsarean section on women who die during labour. After collecting evidence, Winckel finds that the chances of saving the child are considerable, the gloomy prognosis of Fehling and others being set aside by recent experience. The best results have been seen when the child has been extracted within ten minutes after the death of a previously healthy patient from flooding, or of a woman ill but very shortly before the moment of decease (from convulsions of pulmonary embolism, for example). In these cases the child was delivered at or very near term. Living chiidren have, however, often been delivered by section and reared after the death of the mother from chronic cardiac or pulmonary disease. The longest period after death when Cæsarean section has saved the child is from twenty to thirty minutes (Pingler, Brotherston). Even when thet fœtal heart sounds have become inaudible, rapid section has saved the child. The best success, as might be expected, has been obtained in hospitals, where instruments are always in readiness. Winckel recommends Rung's instructions to be followed when death during labor occurs in private practice. Alter all, Winckel remarks, these cases are still rare, and therefore laws cannot well be framed at present to bind practitioners. All cases should be duly reported, and registration authorities should tabulate them especially and with great care as to notification of the result. When

the patient dies suddenly in the presence of the practitioner or just before his arrival Cæsarean section ought to be done at once with any instrument that is at hand. When the patient is sinking hopelessly from convulsions, apoplexy, etc., preparations should be made as complete as possible for the performance of Cæsarean section as soon as the maternal heart ceases to beat. There remains a grave class of cases where, after due consultation, it may be deemed justifiable to deliver the child by section, the patient being *in extremis*. Winckel refers to cases of severe dyspnœa, anasarca, etc. If the fœtal heart sounds can be heard, it may seem right to deliver the child by Cæsarean section, as the very slow death of the mother is more certainly fatal to the child than her sudden decease. —*Brit. Med. Jour.*

THE BACILLUS OF ECLAMPSIA.

The *Deutsche medicinische Wochenschrift* of May 12th contains the announcement that Dr. Gerdes, first assistant in the Pathological Institude to the University of Halle, has in a severe case of eclampsia succeeded in demonstrating by culture the presence of a short bacillus in the liver, lungs, and kidneys, and also in the blood. The bacillus is extremely virulent when inoculated in rats and mice, causing convulsions in the latter. In all the animals experimented on coma set in, the respiration became shallower, the body temperature became subnormal, and death occurred in a short time. In guinea-pigs convulsions only came on after intravenous injections (the jugular vein was selected for the purpose); subcutaneous and intraperitoneal injections produced no such effect. The bacilli referred to were found in great numbers in the lungs, kidneys, and liver of patients suffering from eclampsia, especially in the form of bacillary emboli, the starting point of which was probably a primary focus in the placenta. Dr. Gerdes promises a preliminary communication on the subject without delay.—*Brit. Med. Jour.*

GYNECOLOGY.

ICHTHYOL IN DISEASES OF WOMEN.

Eschen(*Gynek. op Obstet. Meddelelser*, 1891, vol. viii, p. 192) used this drug in twenty-five cases. Good effects were observed in patients with metritis, parametritis, and inflammation of the ovary, but it is admitted that no extraordinary effects were observed.

REPRODUCTION OF THE UTERINE MUCOUS MEMBRANE.

L. M. Bossi (*Brit. Med. Jour.*, Nov. 7, 1891) gives the results of an experimental study on the reproduction of the uterine mucous membrane after curetting, and after the permanent application of caustics (Canquoin's paste). He first performed laparotomy on bitches and then scraped away the mucosa in the neighborhood of the cervix with a Volkmann's spoon; in other cases the uterus was opened along its anterior surface, and different areas were completely denuded with a bistoury. In the cauterization cases sticks of Canquoin's paste were inserted into the corua and allowed to project a into the uterine cavity. After a varying number of days the animals were killed, the parts hardened in alcohol or in Flemming's solntion, and sections made.

Staining was done by alum and carmine, also by saffronine. Fifty animals were thus experimented on; the results in thirty-five only are relied upon in the following conclusions : 1. The uterine mucous membrane of the dog removed from large tracts and in its whole thickness, is completely reproduced after a time together with true glands.

2. This reproduction may be in some cases a slow process from causes not yet ascertained. 3. The new epithelium is derived from that of the glands at the margin of the wound. 4. Finally, the reproduced glands arise by proliferation of the cells of the new epithelium after it has become cylindrical. As regards caustics, Bossi comes to the conclusion that Tarnier and Polaillon, in their report made to the Paris Academy of Medicine in 1890, are in error in stating that they removed the mucous membrane in its whole thickness by caustics, They judged only from the expelled eschars and not from direct observation of the uterus. In all Bossi's cases there were incomplete stenosis of the cervical canal and complete stenosis of the cornua,and even signs of peritonitis. Microscopical examinations by the author showed the existence of an intense necrotic inflammation caused bv the caustic, which not only destroyed the mucous mem-

brane, but profoundly altered its glandular apparatus, so that it became impossible to say whether complete destruction would follow, or whether, a *restitutio ad integrum* being impossible, or difficult, grave chronic alteration would remain as the result. In contrast to this, in ten cases of removal of the mucous membrane, and in twenty other cases in which the uterus was laid open and the knife used, there were never any even incomplete stenosis, and never signs of peritonitis or grave inflammation of the uterine walls.

Accordingly Bossi emphatically asserts the superiority of curetting to the use of caustics left in situ, as regards both immediate and ulterior results.

PEDIATRICS.

CHRONIC PERITONITIS IN CHILDREN.

Henoch (*Deutsche med. Wochenschrift*, No. 1, January, 1892)does not believe, as has been taught by West, that nearly all cases of chronic peritonitis in childhood are of tuberculous nature. He does not see why the peritoneum cannot take on a chonic inflammation and cause a serous exudation into the abdominal cavity, just as the pleura takes on an inflammation. He calls particular attention to those cases which only show the presence of ascites, which may be very large in quantity. These cases progress as follows: The children are usually over 3 years of age; they seem to be quite well, do not complain of pain, nor is the abdomen tender to pressure. The only thing that the parents have noticed is an increase of the abdomen. An examination reveals free ascites (author has never seen it encapsulated in this form of cases). No cause for the ascites can be found in the liver, kidneys, or heart. Rarely is it traumatism. Tuberculosis can be excluded in many cases, from the general condition of the child and its ultimate recovery, although at times it may be very difficult to exclude this as a possible cause. The finding of tubercle bacilli, in the fluid which has been withdrawn is often a very difficult task, so that, although they are not found, we cannot say that the case is not tubercular, nor does the use of tuberculin help us in making a diagnosis. The majority of cases affected with this simple form of peritonitis are girls. In boys it occurs very rarely. This leads to the thought of a connection between the affection and genital organs, and it has been stated that a vulvo-vacinitis, which occurs frequently enough in children, may travel up to the uterus, thence to the tubes, and so on into the peritoneal cavity. These cases must be differentiated from a cirrhosis of the liver producing ascites, which can only be done after the fluid has been withdrawn and the liver then palpated; and from tuberculosis, which, as stated before, may be very difficult. The treatment of these cases is a purely surgical one. Medicines, puncture, etc., do little if any good. The ascites returns almost as fast as the fluid is withdrawn. Laparotomy, on the other hand, produces a rapid and permanent cure in these cases, as it often does in tuberculous peritonitis.

RICKETS IN AUSTRALIA.

Muskett(*Australasian Medical Gazette*, July 15, 1891.)says, rickets has been considered a disease of rarity in Australia; but that he has found it to be comparatively common, though as a rule of mild type. Acccording to his description there is nothing in the symptoms especially peculiar. The chief point of interest is the fact that this disease is frequently found by one who is watching for it, and who appreciates its symptoms in a locality where it was supposed not to exist. When the conditions are favorable the disease is sure to appear.

THE PROPHYLAXIS OF SCARLATINAL NEPHRITIS.

In more than a hundred cases of scarlatina seen in the course of six years, in in which the patients were for three weeks kept upon milk diet, Ziegler has not once encountered nephritis as a complication.—*La Semaine Méd.*, No. 4, 1892.

HYGIENE.

A DEFENCE OF TOBACCO-SMOKING.

It is considered by many that tobacco-smoking, like ladies' corsets, is indefensible on hygienic grounds, and that the only reasons for its practice, independent of a patriotic desire to aid the State in the consumption of a dutiable article, and so to in-

crease its revenue—are in the first instance the faculty of imitation, then habit, and over all caprice. It has fallen to the lot of a well-known hygienist of Rome, Dr. v. Tassinari, however, to demonstrate that tobacco-smoking fulfils a valuable hygienic function, viz., that of a powerful disinfectant, making it a prophylactic against a number of infective diseases. In order to show that he does not stand alone in his views, he quotes Drs. Miller, of New York, and Vassili, of Naples, both of whom are of opinion that tobacco-smoke prevents the development of pathogenic germs. A large number of independent investigations were made by Dr. Tassinari on the influence of the smoke of the noble weed on the germs of cholera, anthrax, and pneumonia.

His method of research was to line the interior of hollow balls with gelatine containing the germs of the diseases named: tobacco-smoke was then passed through these globes for from twenty to thirty minutes. The surprising fact was then established that at the expiration of the time the bacilli of true Asiatic cholera and of pneumonia were completely destroyed, whatever the kind of tobacco employed for the purpose. The gelatine was absolutely sterilized by the tobacco-smoke. The anthrax bacillus was more resistent, however, whilst the bacillus of typhoid was scarcely acted on at all. It is too much to expect that tobacco-smoke will destroy germs already domiciled in the system, but it will no doubt afford not a little comfort to smokers to learn that as far as it goes the practice tends to prophylaxis in the case of some of the most serious of the infective diseases.—*Med. Press.*

PASSAGE OF TUBERCLE BACILLUS FROM THE MOTHER TO THE FŒTUS.

Birch-Hirschfeld and Schmal have recorded a case which they consider is the first in which it has been definitely shown that in the human subject tubercle bacilli can pass from the mother to the fœtus. The patient was a young woman who, shortly after the commencement of her first pregnancy, began to exhibit symptoms of incipient phthisis; the disease assumed an acute form, and progressed so rapidly that the patient died during the seventh month of her pregnancy. Immediately after the death of the mother the child was removed by the operation of Cæsarean section. A post-mortem examination was made on the body of the mother. Advanced tubercular changes were found in the lungs, and also some miliary tubercles in the liver and other organs. The child had been felt to move after the death of the mother, but by the time the operation had been performed it was found to be dead. The thorax was at once opened, but the lungs appeared to be quite healthy. The body was then removed to the laboratory, the surface of the abdomen washed with perchloride of mercury, and the cavity opened by means of sterilized knives. No evidences of tubercle could be found in any of the organs. Small pieces of the liver, spleen, and kidney were removed with sterilized instruments, and placed in the abdominal cavity of two guinea-pigs and a rabbit. One of the guinea-pigs died in fourteen days; miliary tubercles were found in the peritoneum and large omentum. The second one was killed about six weeks after inoculation, and the same appearances were noted. The animal had appeared ill, it was feverish, and emaciating rapidly. The rabbit lived considerably longer—three months; after death, tubercles were found in the liver and lung. From these experiments it was evident that although no tubercular lesions could be found in the organs of the child, yet the latter were capable of infecting animals; and had the child survived, it would have undoubtedly developed tuberculosis at an early age. It is a point of great interest to read that tubercle bacilli were found in the umbilical cord and in the blood of the umbilical vein.—*Lancet.*

MEDICAL CHEMISTRY.

A NEW DEPARTURE IN FILTERING APPARATUS

E. Martin has recently devised the following improvement in filtering apparatus. An endless traveling band, made of any material suitable for filtering purposes, is so arranged as to assume for a portion of its length the form of an open horizontal trough or cistern. For this purpose the band is mounted in a manner to cause it to make a slight descent at one end, and and simultaneously to have the two sides or edges of the fabric turned up. In this form the band extends horizontally for a certain length, and is then made to rise again on an incline and to spread out flat.

In this manner a shallow traveling cistern is formed between the two inclines wherein the water for filtering is received.

The speed of the traveling band may be regulated in such a way as to allow it to be coated to any desired degree with the matter arrested from the filtered liquid, and on continuing to travel it may be conducted through cleansing apparatus, whence it will return cleaned and ready for the renewal of the operation.

REACTION OF SALOL.

According to *Journal de Pharmacie d Anvers*, the following is a characteristic of salol. A small quantity of salol is added to a few drops of nitro sulphuric acid. The mixture is colored yellow and on stirring with a glass rod it changes to brown and then to green. On diluting with about 50 gm. of water the liquid assumes a rose color, the green color reappearing on adding ammonia. Resorcin treated in the same manner gives a deep blue color; on dilution, red. In the latter solution, ammonia causes the blue color to reappear.

DELICATE TEST FOR ALUM IN DRINKING WATER.

E. H. Richards contributes to *Technology Quarterly* the following, which it is said, will detect 1 part of alum in 1,000,000 parts of water (1 grain in about 17 gallons): To 25 ccm. of water (concentrated from 1 litre or more if necessary,) are added a few drops of freshly-prepared logwood decoction; any alkali is neutralized and the color brightened by the addition of two or three drops of acetic acid. By comparison with standard solutions the amount of alum present may be determined. The logwood chips must be treated with boiling water two or three times before finally extracting for the color, as the first extraction gives a yellow color, the third or fourth a deep red.

A NEW SOLVENT OF CAMPHOR.

From the frequency with which the indications for the subcutaneous injections are met with it is evident that a good and reliable solvent for this substance is a great desideratum.

Ethereal solutions rapidly evaporate. Alcoholic solutions also evaporate and the camphor becomes precipitated, so that injections of such solutions produce severe pain or even abscess. Solutions of camphor in oil are difficult to employ, besides possessing the disadvantage of the liability of becoming rancid.

In the *Zeitschrift für Thèrapie* for September 1st, 1891, Dr. Karl Rosner recommends in the highest terms a solution of camphor in liquid paraffin, which, when slightly warmed, forms a perfectly clear and limpid solution. He states that he has kept this solution for more than five years without its properties becoming changed.

NEWS AND MISCELLANY.

INTERNATIONAL DERMATOLOGICAL CONGRESS IN VIENNA.

The second meeting of the International Dermatological Congress will be held in Vienna from the 5th to the 10th of September 1892.

Many of the most distinguished representatives of dermatology and Syphilography from all countries have promised to present papers and the indications are that the meeting will be a great success from a scientific standpoint.

The committee on organization, through the President, Prof. Kapesi, has extended a cordial invitation to the members of the American Dermatological Association and of the New York Dermatological Society and others interested in Dermatology in this country to be present.

The membership fee (five dollars) should be sent with titles of papers intended for presentation to the Secretary for North America, Dr. Prince A. Morrow, 66 West 40th street, New York, or to the Secretary General of the Congress, Dr. Gustav Riehl, Wien $^{1}/_{9}$, Bellaria Strasse 12.

A successful case of bone-grafting is reported from Allahabad, a solution of continuity in the anterior layer of the frontal sinus having been induced to take on osseous repair by sprinkling the surface with "small fragments" of the hip-bone of a newly killed dog.—*Med. Press.*

SODA.

Caffein 1 Grain, Bromide Soda 30 Grains in each heaping teaspoonful.

USEFUL IN

Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Sea-sickness, and Epilepsy.

Dose and Composition.—A heaping teaspoonful, containing Bromide Soda 30 grains, and Caffein 1 grain, in half a glass of water, to be repeated once after an interval of 30 minutes, if necessary.

ANTI-RHEUMATIC. SEDATIVE.

EFFERVESCENT.
BROMO
(WARNER & CO.)
LITHIA.

EACH DESSERTSPOONFUL CONTAINS:
℞ Salicylate Lith a 10 grains, and Bromide Soda 10 grains.

A REMEDY IN THE TREATMENT OF
RHEUMATISM, GOUTY DIATHESIS, ETC.

Dr. A. Garrod, the well-known English authority on Gout, who was the first physician to introduce the Lithia Salts in the treatment of Gouty Diathesis, states that their action is materially increased by being administered in a *freely diluted form.*

This effervescing salt of Lithia furnishes an easy and elegant way of applying Dr. Garrod's methods.

INGLUVIN

A SPECIFIC FOR VOMITING IN PREGNANCY.
A POWDER:—PRESCRIBED IN THE SAME MANNER, DOSES & COMBINATION AS PEPSIN
In Doses of from 10 to 20 Grains,
AND A POTENT AND RELIABLE REMEDY FOR THE CURE OF
Marasmus, Cholera Infantum, Indigestion, Dyspepsia and Sick Stomach,
caused from debility of that organ. It is superior to the Pepsin preparations, since it acts with more certainty, and effects cures where they fail.

"CURIOUS QUESTIONS."

An Encyclopaedia of the Rare and Curious.

Third Improved Edition Now Ready.

"Curious Questions" fills a niche wholly its own. Its mission is to tell you hundreds of things that you ought to know, and don't; to enlarge your conversational powers; to brighten your intellect, and lead you to further research in the best channels of thought, and to keep you from exposing your ignorance on many questions of daily recurrence.

Do not think you are too wise to profit by it, when Rev. Dr. Andrew Preston Peabody, of Harvard University, says of "Curious Questions:"

> **"I find that some of the questions are such as I could not have answered, or have known where to look for their answers. Such a book will be of inestimable service and value to any intelligent person, young or old."**

The new de luxe editions (25 full-page illustrations) are unexcelled for presentations. Prices, $4 00, $6.00 and $8.00 a set.

Sold by subscription through our regularly authorized solicitors, or supplied direct by the publishers. Illustrated descriptive catalogue and sample pages free. *Agents wanted.* Address the sole publishers,

ECLAMPSIA.

By DR. ROBERT OLSHAUSEN,
BERLIN, GERMANY.

PART II.

(*Continued from page* 5.)

THE PATHOLOGICAL ANATOMY OF ECLAMPSIA.

Gentlemen:—If we now proceed to a consideration of the pathological anatomy of eclampsia, I must first state that changes in the kidneys are found in all fatal cases.

In twenty-two cases of thirty-seven, I found in the kidney evidences of acute or subacute processes, which principally affected the parenchyma of the kidney, and then would either cause an acute fatty degeneration of the epithelium of the kidney substance (so-called "kidney of pregnancy") yet seldom affecting the glomeruli or else it would reveal itself in a severe change of the parenchyma. In two of these cases the pathological changes were only of a slight degree. In other cases there existed simultaneously a chronic interstitial nephritis, to which the acute changes of the parenchyma had been added. Five such cases were found. Four were found in which there was only the interstitial nephritis. In one case there was a chronic interstitial nephritis on the left side, and a recent parenchymatous nephritis on the right side. Usually the parenchymatous changes affected both kidneys. In the majority of cases of simple or complicated parenchymatous changes there were numerous apoplexies of the parenchyma; this also occurred in one case of glomerulo-nephritis.

In two other cases there was only a hyperæmia of the kidneys, although to be sure the patient did not die until the twenty-ninth post-partum day, and then with pneumo-thorax. In this case, the renal symptoms had doubtlessly receded.

In one case only were we unable to discover any pathological change in the kidney. The patient had had twenty-one eclamptic attacks, half of which occurred post-partum, and died on the fifth day after delivery, from pneumonia. Perhaps in this case also the pathological conditions of the kidneys had receded, for during the eclamptic attacks her urine contained large quantities of albumin (¾ of its volume) as well as many hyaline and granulated cylinders, renal epithelium and red blood-corpuscles.

In the last of the thirty-seven cases both kidneys were found diseased in an extraordinary way, and this case is of special importance in reference to the meaning of eclampsia, and of special general interest. The right kidney was a so-called "fœtal cystic kidney," only about the size of a pigeon's egg. The right ureter was of unusual smallness, and thread-like. The left kidney was hydroscopic in a high degree, so that it only consisted of a single pyramid. The left ureter, from the entrance of the pelvis up, was enlarged to the size of one's little finger. We shall return to a consideration further on.

I add to this description of the pathological anatomy of the kidneys that of the ureters. In the thirty-seven cases in which I performed autopsies, the right ureter was found dilated in five instances, but only moderately and without, or at least very slight, hydronephrosis. In one case I found slight right-sided hydronephrosis without dilatation of the ureter. In a seventh case, finally, there was a left-sided hydronephrosis with dilatation of the ureter, and at the same time a right-sided cystic-kidney.

More, even, than the frequency of the attacks, must their character or nature be taken into consideration. In such cases of eclampsia in which the disease appears at the end of birth, or more frequently even during the first hour after the birth, and then ceases after one or two convul sions—in such cases the convulsions are usually of a light nature.

On the contrary, there rarely occur cases of eclampsia, of the most unfavorable prognosis, which occur sometimes intra-partum and sometimes post-partum, in the intensity of the convulsion is the most important feature. In these, the attacks occur, as a rule, in quick succession, and nothing but the most energetic use of morphine will influence them in any way whatever.

Any great increase of temperature must be regarded as a most unfavorable symptom. In thirty-seven cases there was a rise of temperature of 39° C. or over, either during the attacks or in the coma that followed; of these thirty-seven cases, fifteen died, or 40.5 per cent. In twenty-seven cases in which the temperature did not exceed 39.9° C., there were nine deaths, or 33⅓ per cent.

The rise of temperature depends greatly upon the number of convulsions. This may be seen by the following: In thirty-one cases in which the temperature reached 39° C. or over, the average number of convulsions was fifteen, while on the contrary in one hundred cases in which the temperature did not reach 39° C., the average number of attacks was only nine.

Of still greater importance than the temperature, is the pulse. When the pulse increases in poorness, that is in smallness and frequency, whether during the convulsions or after they have ceased, it is always a bad symptom.

In the majority of cases the prognosis remains very doubtful, not only during the continuance of the convulsions, but also during the coma. Subsequent diseases must also be taken into consideration, among these may be mentioned lung troubles (pneumonia) and septicæmia, as playing the most important rôle. From the first cause three of our patients died, and from the last, four.

The frequency of sepsis in eclampsia may be seen from all statistics of the disease. Löhlein, out of one hundred and six cases of eclampsia, reports forty deaths and four cases of sepsis; Brummerstädt out of 135 cases of eclampsia reports fifty-one deaths and thirteen cases of puerperal infection. C. Braun, out of forty-four cases, reports nine of puerperal infection, five of which ended fatally; Schauta out of 90 deaths from eclampsia, reports that twenty-seven were from peurperal infection. In Löhlein's latest statistics, there were to be seen only four cases of sepsis and pyæmia in three hundred and twenty-five cases of eclampsia. Yet it is very possible that in the thirty different reports from which these statistics are compiled, this point may not have received special consideration in some of them. The frequency of septic infection may be explained by the frequency of operative interference, but may also be connected with a certain predisposition to septic infection, on the part of eclamptic subjects, similarly as acutely anæmic subjects are liable to septic infection.

The prognosis for the child is even worse than for the mother.

When we look aside from cases of pure puerperal eclampsia, and also from such cases of eclampsia occurring in pregnancy in which the disease did not terminate the pregnancy (5 cases), further also from such cases in which the death of the mother occurred, ante-partum (9 cases), and finally from those cases in which at the time of the interruption of pregnancy by the disease, the fœtus was not yet viable, there remain still (153) children, of which forty-three were brought into the world dead; giving thus a mortality of 28 per cent.

The number of convulsions and the frequency of their recurrence affects the life of the child even more seriously than that of the mother. After twelve or thirteen attacks the child usually dies, and often even long before this. Yet we have thirteen cases to report in which the children were born alive, although they had endured fifteen convulsions while yet in the mother. But the majority of the children who had lived through so many maternal convulsions, died the next day.

The narcotics which we are frequently compelled to make such free use of, are also undoubtedly deleterious to the child's life. After the use of full doses of morphine we have frequently seen the children born to the world deeply narcotised by the drug. Even when all signs of asphyxia

were absent, the respirations of the child were always shallow and slow, and its movements were few and torpid. Occasionally the pupil was fixed and contracted. Some of these children, although breathing regularly, could not be made to cry, by any exciting means.

A superficial examination of such children would lead one to believe that they were asphyxiated, but a closer view will soon reveal the true state of affairs.

THE THERAPY OF ECLAMPSIA.

The therapy of eclampsia has heretofore been one of pure empiricism. In distinction to the largely used treatment by chloroform anæsthesia, which has been so extensively employed, as it was also at this clinic, I prefer the use of morphine in large doses, as suggested by G. Veit. As an initial I give 0.03 gramme, hypodermically, and if the convulsions do not cease soon follow it by additional doses. In the course of treatment we seldom give over 0.06 gramme, or indeed altogether, although in cases that progressed chronically we have, during the course of several days given much more; in one case giving as much as 0.27 gramme in four days, with good results to the mother.

When the condition of the pupils or of the pulse would indicate that the further exhibition of the drug is not advisable, and in case the attacks still continue, I substitute chloral, by rectal injection, in 2.0 or 3.0 gramme doses.

The use of chloform seems eminently suited in those comparatively rare cases, where the attacks return after pretty regular intervals. In all other cases one must either prolong the anæsthesia for a very long time —which to us does not seem advisable—or else administer an anæsthetic at the first intimation of the approach of an attack; in this latter case, however, the remedy always comes too late to abort the attack.

During the continuance of the eclampsia, we make no use of either diaphoretics, bromides, wet-packs, or baths. Indeed we shun all unnecessary handling of the patient, because this only too frequently will excite an attack. There have been cases in which a careful digital examination of the uterus, the expression of the placenta, a change of the patient's bedding, and even the puncture of the hypodermic needle have been sufficient to excite a convulsion.

When in deep coma, the rattling in the upper air passages becomes continued, asphyxia is imminent. This can be prevented by bending the patient forward over the side of the bed, so that the head is greatly lowered. In this way very large quantities of mucous will be discharged from the mouth, the respiration will become free and the cyanosis will disappear. The mucous may also be removed with small brushes of cotton or small sponges, which are inserted into the flames, one after the other, by the dozen. In this way the same results are obtained. In many cases I feel convinced that we have saved our patients from an immediate death from asphyxia by these means. I also claim the great importance of the watchful care of a physician at the bedside of the patient, so as to be always ready in case of any such emergency. In Löhlein's recent publication on the subject we may read that Schatz recommended the frequent sinking of the head of eclampsties, but apparently not for the same reason.

Regarding operative interferences, v. Herff's* recently recommended practice of rupturing the amniotic sac in order to accelerate the birth, is at all events worth the trial, and in multiparæ may be regarded as a pretty certain means of accomplishing this end. The frequent use of the forceps in cases of well dilated cervix with a deep position of the head, is equally recommended on all sides. Version, for instance, in cases of a contracted cervix, and extraction with the aid of free incisions, does not seem to me to be recommendable. On the contrary, I consider Cæsarean section as practiced by Halbertsma and Kaltenbach—the requirements of v. Herff being fulfilled—as a both justifiable and valuable procedure. The requirements of v. Herff are to the effect that if the child is still alive in a severe case of eclampsia, and a natural birth is impossible, or the dilatation of the cervix is delayed, then this operation is justifiable. Now, when the mortality of the operation has been so greatly reduced, a successful result is very possible.

In how far the use of the forceps and version affect the mortality, I should like to elucidate by giving the following data: Out of sixty-four forcep deliveries, ten

*v. Herff, *Berliner Klinik*, Heft 32, 1891.

died; while in nine cases of version, five resulted fatally.

If we look aside from the ten deaths occurring ante-partum, the mortality table might be arranged as follows:

In 111 spontaneous births, there were 24 deaths, or a death rate of 21.6 per cent.; while in 77 of instrumental deliveries, there were 16 deaths, or a death rate of 20.8 per cent.

Among the last were included at least three cases of sepsis. If those cases in which version was used were to have been excluded from the statistics, the death rates in favor of the operative births would have been still more favorable.

That the termination of delivery beneficially affects the disease—since in a large number of cases the attacks then quickly cease—is denied by both Brummerstädt and Schauta. But all the same the clinical facts undoubtedly point to the beneficial influence of a speedy termination of the birth. If I search through my own cases and see what sort of an answer they would return to such a question, I find the following:

In seventy-three cases of spontaneous births, no attacks occurred after delivery in forty-three cases, and three or over in thirteen patients.

In seventy cases of operatively ended pregnancy, no attacks occurred after delivery in forty-nine cases; one or two attacks in twelve cases, and three or more attacks in nine cases.

In 143 cases, the eclampsia ceased with the completion of delivery in ninety-two cases. It returned once or twice in twenty-nine cases, and more than three times in twenty-two instances.

In about 85 per cent. of cases the eclampsia ceases with delivery, or else soon after.

(*To be continued.*)

CHOREA.

Out of a total of 18,074 children treated in five years at the polyclinic of the Charité in Berlin, Meyer found 121 instances of chorea, or a proportion of 6.6 per cent.; 11 of these cases (nine per cent.) were at the same time rheumatic; 3 had, along with their rheumatism and chorea, an organic affection of the heart; 13 (ten per cent.) had chorea and heart disease without the rheumatism.—*Berliner klin. Wochens.*

THE OPERATIVE TREATMENT OF CLUB-FOOT; THE DIAGNOSIS AND TREATMENT OF HIP-JOINT DISEASE.

By A. M. PHELPS, M. D.,

PROFESSOR OF ORTHOPEDIC SURGERY, N. Y. POST GRADUATE MEDICAL SCHOOL AND HOSPITAL, NEW YORK CITY.

Gentlemen:—I shall first operate upon this case of double congenital club foot. This little baby 7 months old, has a talipes equino-varus of the left foot, and a varus of the right. Instead of treating it for many months by instruments, I propose to divide at once the contracted parts, placing the foot in a super-corrected position, and dressing it with plaster of Paris. We can accomplish more in a few moments in this way, with equally good result than can be done by three or four months of careful treatment with the best machines that have ever been devised. Always remember in operating for club-foot: First, to manipulate the foot thoroughly in order to overcome the contract*ed* parts; this will put the contrac*tured* parts on the stretch; secondly, perform subcutaneous tenotomy on the parts which first offer resistance, and in the order in which they became contracted, beginning with the tendo Achillis. Having severed this tendon, pull the foot as nearly as possible into position; then cut another resisting portion, then manipulate the parts again before cutting any further, and if you find that the skin, is short and resisting, make an open incision, beginning just in front of the inner malleolus, and extending one-third the distance across the foot, putting the deep parts on the stretch by manipulation and then cutting them if necessary. If this fails to relieve the deformity, do a linear osteotomy through the neck of the astragalus; if this fails, remove a V-shaped piece from the astragalus; failing in this, remove the cuboid and scaphoid; and if you are still unsuccessful, perform Pirogoff's amputation. Of course, I am talking to you about extreme cases when alluding to amputative extensive osteotomy.

Having now divided the tendo Achillis in the right foot of our little patient, I shall endeavor to put the foot in a super-corrected position of calcaneus. As this cannot be done, I again introduce my tenotome through the same incision, and di-

vide any contracted bands that may be present. The abductor pollicis and the plantar fascia are next divided, and after further manipulation, I find that the long flexor of the great toe is short, so this is divided, and I am now able to super-correct both the varus and the equinus. To stop short of this, would be a great mistake. The foot is now dressed with Lister's "protective," and gauze, "bunching" it up over the wound on the plantar surface so as to make a little more pressure at this point, and so control the oozing of blood from the divided muscular branches. A gauze bandage, and a plaster of Paris dressing complete the dressing. It is only necessary to cut the plantar fascia in the left foot, and apply the same dressing. Only do open operation when subcutaneous ones are not safe nor efficient.

I shall next invite your attention to the general principles underlying the diagnosis and treatment of hip joint disease, and I shall begin by showing you this little girl with double congenital dislocation of the hip as I shall again allude to it when speaking of differential diagnosis. This child is wearing a machine which I devised, and which consists of a band around the hips, and two perineal straps, with adjustable and even pads so arranged that greater or less pressure may be made over the great trochanters, thus pressing them firmly against the ilium, and overcoming the tendency of the head of the bone to slip up on to the dorsum.

Our next patient is a little girl with true inflammatory disease of the hip joint. The joint is extremely sensitive, and is filled with fluid. Now, what are the general symptoms of joint disease? They are, pain, heat, swelling, pain on joint pressure, limited motion, spasm of muscles, atrophy, and deformity. What are the symptoms of hip-joint disease? All of these eight, and a few others. Patients with hip-joint disease have pain in the *knee*, flattening of the buttocks, obliteration of the gluteal fold, flexion of the limb, and in the first and second stages, abduction and apparent lengthening. If there be true disease of the bone, there is also atrophy of the limb; Barwell of England first called attention to this fact. In the case before us, there is no difficulty in determining an increase of local temperature, the presence of swelling, and the limitation of motion. To ascertain whether or not there is abduction, place the patient on the back in such a position that a line drawn between the anterior superior spines of the ilium will be parallel to another line drawn across the body at a higher level, and then noticing the position of the limbs with reference to the median line. In testing for flexion, we place the limb so that the popliteal space touches the table, when we find that the buttock arches very slightly, showing that there is still in this patient a little flexion. Thomas's method is also a good one. This deformity is due to spasm of the iliacus and psoas muscles. There is also some atrophy of this child's limb. The symptoms, then, would lead you to believe that this child had joint disease, but we would have nearly all these symptoms with sacro-iliac disease, or with disease located in the acetabulum external to the joint. If with your hands pressing firmly both iliac crests towards the median line, pain is not elicited we may know that there is no sacro-iliac disease. If the disease was located external to the acetabulum, or was extracapsular, you would have all the symptoms present in this case, *except pain on joint pressure.* But we have not yet differentiated between disease of the bone and of the soft parts. I know that there is disease of the bone here, because of the rapid atrophy of the soft parts. When the terminal plates of the nerves within the area of disease are pressed upon, the muscles supplying the diseased joint are, by reflex action, thrown into spasm; but when the soft parts are diseased, on account of their elasticity, but little pressure is made upon the nerve plates, and hence there is slight muscular spasm, slight deformity and slight atrophy.

Let us now differentiate between a true inflammatory disease of the joint, which has resulted in destruction of that joint, with possibly a dislocation and a case of congenital dislocation of the hip, or one of intracapsular fracture, or a diastasis of the head. If the great trochanter be above Nelaton's line, namely, a line drawn from the anterior superior spinous process of the ilium to the tuberosity of the ischium, you may know that there is a dislocation, a diastasis, an extracapsular fracture, or hip-joint disease. This child's great trochanter does not project above Nelaton's line. Many cases of hip-joint disease come to you after dislocation has taken place, and you will find from two to four

inches of shortening. How shall you distinguish between them and a case of congenital dislocation of the hip? Let us look again for a moment at the first case, the little girl with congenital dislocation of the hip. You would look for limited motion in every direction in case of hip-joint disease, but on examining this case, I find nearly perfect motion, no history of inflammatory action, and I can both feel and see the head of the bone as it rotates. If the dislocation were due to inflammatory disease, we would expect to find the head of the bone held up against the lium, and probably not smooth, but more or less distorted. Is this a case of diastasis, or a true case of dislocation? I know it is not a diastasis, because I can feel the head of the bone, and because when I rotate the limb, the trochanter rotates in a circle, which it would not do if there were a diastasis. The mother says there has been no injury, hence, the condition must have occurred at birth, or in utero. No method of treatment with which I am familiar will effect any great improvement in the condition of such a case of double congenital dislocation of the hip short of an operation, and the contrivance for making pressure on the trochanters seems to me to be as useful as any yet devised. If there be a difference in the length of the limbs, of course, this should equalized by a high shoe.

Now, in regard to the treatment of hip-joint disease, let me, in the first place, impress upon you that it is a surgical law which no general or orthopedic surgeon should violate, *that when a part is inflamed, that part should be put at rest until it is cured, no matter how long a time may be required to effect this.* Another important rule is, *overcome the spasm of the muscles operating upon the joint*, as this spasm produces *great intra-articular pressure*, and will certainly result in the destruction of the joint if not controlled by traction exerted *against the contracted muscles.* To do this, you must make not only longitudinal traction in the line of the deformity, *but also lateral traction in the axis of the neck to overcome the spasm of the adductors and the abductors.* Another important point is, *when will you begin passive motion? Never.* I care not how long you keep the joint immobilized, *it will not be anchylosed, because of the rest you give it;* but *if anchylosis does occur*, it will be *on account of the duration, severity and extent of the inflammation, and the subsequent cicatricial contraction, and no amount of passive motion will prevent this after this cicatricial contraction has once begun.* Therefore, I say, put all patients with sensitive joints *to bed, and also those having deformity*, because you can overcome the deformity more quickly with them in bed. After the deformity has been reduced, and all tenderness has disappeared, put the patient on a lateral traction fixation splint. *Never allow them to walk upon the splint until cured, for the constant trauma produced by walking will prolong the disease, and more than fifty per cent. of such cases so treated have anchylosis, and hardly a single case will recover without deformity;* hence, *you must use a high shoe on the well leg, and not allow the splint to touch the ground.* These are the principles of treatment, and if faithfully carried out, I think they will enable you to obtain far better results than have hitherto been observed in hip-joint disease. We seldom see anchylosis and our cases are treated as I have suggested. All recovered without angular deformity.

Another important question which will confront you is, when shall you operate upon an abscess? *I answer, just as soon as you are sure pus is present, except when the abscess causes no disturbance, there is no tendency to burrowing, and occasionally also where the abscess is so located, that if opened, the ring of the brace would press upon the wound. "An empty house is better than a bad tenant," and I have never regretted opening an abscess.* Having incised an abscess, you can then *introduce your finger*, and ascertain positively the exact condition present. *You may find the head of the bone separated from the shaft, or you may find positive indications for an incision, at any rate, by opening an abscess, you are made master of the situation.*

In connection with the subject of immobilization and anchylosis, I would like to show you this man, who is *said to have had inflammatory rheumatism*, and whose *entire spine* is *anchylosed*; yet, *his spine has been constantly moved and subjected to all kinds of massage*—the very plan which is supposed to prevent anchylosis, but anchylosis has resulted. *Are you going to*

bow down humbly to established precedent, or are you going to accept these facts, and shape your treatment accordingly? Contrast this with the next patient, a man who had an effusion in the left knee joint, *nine months ago*, and whose limb was put up in plaster of Paris, *first for five months*, and subsequently again *for four months*. The splint has been removed today, and you see that there *is no anchylosis* in this knee joint *notwithstanding such prolonged immobilization*. If you consult Dr. Sayre's book on Orthopedic Surgery, you will find a case of hip-joint disease reported, in which a child was kept in a wire cuirass for a few months, and the child not only came out with anchylosis of the opposite hip, but of the joints of the opposite extremity, and of the entire spine, and this was attributed to the immobilization; yet strange to say, the side in which the disease existed, recovered without anchylosis. A mistake in diagnosis was certainly made. *By all means do not employ passive motion*, but *active motion*, after the patient is cured; let the patient loosen up the joint, his feelings will regulate the degree of motion. Passive motion will probably excite a fresh inflammation, which will probably result in anchylosis.

The last patient I shall show you is a physician, forty-one years of age, who had an extremely severe form of talipes equinovalgus. I could not straighten the left foot, you will remember, after the open incision, or by manual force, but with the aid of a powerful club-foot machine, I succeeded in pulling the heel down, and I think the result will be very satisfactory. You will remember that we divided the nerve; it is always better to cut a nerve than leave it upon the stretch, for sensation will invariably return. In this patient, it is already beginning to return.

Without the machine, some form of osteotomy would have been necessary, but as there is a mortality of from three to five per cent. from osteotomy, it should be avoided whenever possible. If you follow the rules already laid down, you will probably be able to avoid it in about ninety per cent. of all your cases. The open incision has its legitimate place in surgery, between subcutaneous tenotomy and osteotomy. This patient was my two hundredth case, and I have never heard of a single death from this open incision method.—P.S. Three months later the patient was discharged with perfect feet.

THE INFLUENZA WAVE IN EGYPT.

The influenza wave which attacked Egypt on the Mediterranean border of the Delta, after gradually spreading southward, has now reached the Soudan, into which it is apparently disappearing. The influence of the disease on the mortuary returns was first apparent in Lower Egypt in the week ending January 14th last, when the death-rate went up from an average of 41.9 for the preceding six years, to 52.8 per 1,000 in nineteen of the principal towns. The high rate steadily increased up to February 4th, when the rate was given as 71.9, against the average of 42.8. The following week it began to diminish, but it was not until the week ending March 24th that the normal rate of mortality was again reached. During these eleven weeks the deaths of 358 natives and 24 Europeans were reported as directly due to influenza. In the eleven towns of Upper Egypt, from which returns are furnished, the most southern being Esneh, the death-rate did not show any increase till the week ending February 18th, when it rose to 46.9, the average being 37.1. The highest rate reached was during the week ending March 10th, when 55.6 per 1,000 was recorded; but at the date of the last return, that is, March 31st, it was above the average, being 49.8. In these eleven towns the number of deaths ascribed directly to influenza during the period was 45. The military report from Assouan show that between February 14th and 27th 44 cases of influenza were treated among the soldiers, while at Wady Halfa the number was 132, with one death. From the latter date to March 19th, 3 fatal cases occured at Assouan, and 173 at Wady Halfa; and at the latter station there were 5 deaths. There were only 4 cases left under treatment, so the epidemic may be looked on as almost extinguished as far as the military are concerned. In the week ending April 7th the mortality in Upper Egypt fell to 43.9 per 1,000, although there were 5 deaths said to be due to influenza. At Wady Halfa, on April 9th, there was a clean bill of health from the military hospital as far as the epidemic was concerned, but since the date of the last report there had been 3 deaths.—*Brit. Med. Jour.*

Communications.

REPORT OF A FEW LAPAROTOMIES DONE IN THE ALLEGHENY GENERAL HOSPITAL. BY R. STANSBURY SUTTON, M. D., GYNÆCOLOGIST TO THE HOSPITAL.

By MARK A. RODGERS, M. D.

Before submitting the reports of these cases, I shall attempt to describe the operator's technique.

The method employed by Dr. Sutton for the disinfection of the skin, is that which has been described at various times by Mc Lean and Welsh of the Johns Hopkins University, with slight modifications. Without pointing out these modifications I shall describe the method as used by Dr. Sutton:

1. The forearms and hands of the operator and his assistants are vigorously scrubbed with a coarse sterilized nail-brush, warm water and soap, for several minutes; nails pared and cleaned.

2. The hands are then placed in a strong solution of potassium permanganate for one or two minutes, after which the excess of this solution is washed off with distilled water.

3. They are then placed in a freshly prepared solution of hyposulphurous acid until decolorization is effected.

4. They are then immersed in distilled water.

The hyposulphurous acid solution is prepared by mixing just before using, concentrated solutions of oxalic acid and hyposulphite of soda; the result being the formation of sodium oxalate and the liberation of the acid, which has great decolorizing power, and quickly removes the stain of the permanganate.

The remarkable point to be observed in this process of disinfection is the absence of corrosive sublimate. The results as will appear from the following report apparently justify its omission.

As an additional precaution, the surgeon, his assistant, the nurses and all who are in any way engaged in the operation, receive prior to entering the operating room, a bath, after which they are dressed in sterilized wash clothing.

The abdomen having been prepared with all attention to the details of modern asepsis, the patient is placed after anæsthetization on an Edebold table. The abdomen is opened by three incisions, as follows: The first exposes the linia alba; the second the peritoneum, and the third after the arrest of hæmorrhage, opens the abdominal cavity. The time occupied by this part of the operation is usually from ten to fifteen seconds. The incisions are made by a long continuous sweep of the knife, and the length of the incision has therefore not much effect upon the time required. The cavity opened, the operation proceeds, of course, as required by the existing condition. The general points being, that flushing, sponging and drainage are to as great an extent as possible evaded; that chemicals are never used within the peritoneal sack under any circumstances. Hæmorrhage is controlled by the usual methods—torsion, suture, ligature, sponge packing, hot douche or in extreme cases, styptics. Occasionally despite these measures persistent oozing has to be dealt with, and under such circumstances drainage is reluctantly resorted to, combined with extra-abdominal compression after closure of the wound.

Silk, which is completely soluble in a concentrated solution of potassium hydroxide, is the material used for ligature. The abdominal wound is also closed with silk, with if necessary superficial sutures of silk or cat-gut.

The dressings are extremely simple, consisting of eight layers of sterilized gauze, which after removal from a solution of 1:500 bichloride of mercury, have been rung out in three changes of distilled water. On this is placed a layer of aseptic cotton and the whole held in place by a many-tailed binder. This dressing is not molested under ordinary circumstances until the seventh day, at which time every alternate stitch is removed; on the eighth day the remaining sutures are withdrawn. At this time union has usually taken place throughout by first intention. A single layer of gauze is now applied and held in place by adhesive strips, which also serve to support the wound. This is only changed for the remaining few days as cleanliness or the patient's comfort dictate. On the fourteenth day the patient is usually allowed to sit up, and a few days later leaves the hospital.

The operating room is a model. Through the liberality of Mr. D. E. Park, a member of the board of directors of the hospital, an operating room has just been completed for the Gynæcological department, which is probably, both from an esthetic and practical point of view second to none in this country. It is situated on the third floor of the building and is accessible from all floors by a hydraulic elevator, large enough to carry comfortably a bed or operating table and attendents. The room has a southern and eastern exposure, the high elevation besides giving a good quality of air and making ventilation consequently perfect, gives excellent opportunities for lighting, which in the Smoky City is a matter of no inconsiderable moment. But this element has been bountifully supplied by the designer, Dr. Sutton. The entire front is of glass; there is also a large glass plate in the front eastern exposure. The floor is of white Georgia marble and the walls support a six-foot wainscot of the same material. Above the marble the walls are finished in lead of a delicate blue hue, which is tastefully offset by the ceiling in white. On the eastern aspect from before backward are respectively the glass, a large sterilizing gas range embedded in enameled porcelain bricks, and a six-foot horizontal slab of marble, in which are set three basins; the latter is surmounted by a large highly polished copper reservoir for hot water. The plumbing is in brass, making the beautiful contrast which is so familiar.

Adjoining this and connected with it is a room of smaller dimensions, finished by Mr. S. P. Harbison, also a member of the hospital board, in exactly the same manner, with the exception that the wainscoting is here four instead of six feet. This admirable little apartment, is used as an anæsthetizing, dressing and examining room.

The facilities for operating are exquisite. The material of the floor and walls permits the practice of the most thorough measures known for disinfection and the establishment of perfect asepsis.

Since the election of Dr. Sutton as Gynacologist to the Allegheny General Hospital I have had the pleasure of assisting him at the following operations at that institution:

Case No. 1.—Ovariotomy. Diagnosis: Multilocular cyst of right ovary. Admitted to Allegheny General Hospital, March 23, 1892.

History.—Patient Mrs. G., aged 55 years, had given birth to four children, the youngest at that date being something over thirty years of age. Family history negative.

Personal history.—No history of dystocia or menstrual disturbance. About one year prior to admission to hospital, patient's attention was attracted to tumor-like mass in lower right abdomen, which rapidly grew in size until the (then) present time, when she applied for admission to the hospital for purpose of having operation done.

Operation March 26, at 9 A. M. Abdomen was laid open from umbilicus and cyst delivered after the method of Peon. Proved to be cyst of right ovary, multilocular, weighing 16 pounds. Pedicle was rather broad and was ligated with silk. Left ovary was found to be in a state of cystic degeneration and was also removed. Omentum was adherent to abdominal parietes, cyst and intestines had bled freely; hæmorrhage controlled by silk ligatures. Abdomen flushed and closed. Time of operation, thirty minutes.

Patient rallied well; temperature same evening 99 4-5° pulse 104. Rested quietly and passed gas during the night. On the third day uncontrollable emesis set in which became fecal on the seventh day. At the appearance of the latter symptom, no movement of the bowels having occurred, the patient was placed on the operating table and an incision made in the left inguinal region, and a protruding portion of the ileum stitched to the abdominal wall. An incision was then made into the gut, which was followed by a very large watery evacuation, with much flatus. At this time stitches were removed from primary wound, union having taken place throughout by first intention. The opening of the ileum was followed by a temporary improvement in the patient's condition. The emesis ceased and she partook of considerable nourishment and stimulant. Four days after, however, the emesis returned; patient became exhausted, passed into a typhoid state and died on the fourteenth day.

At the post-mortem the ileum, colon and rectum were found to be in a condition of gangrene. There was no effusion or other evidence of inflammation. The

theory is advanced by Dr. Sutton that gangrene was due to embolism of mesenteric arteries. The emboli being derived from a large varix just below Poupart's ligament and connected with the femoral vein.

Case II. Double salpingo-oöphorectomy. Diagnosis: Gonorrhœal salpingitis. Admitted to Allegheny General Hospital, March 5, 1892. Awaiting operation on Dr. Sutton's arrival. Miss O., aged 19. Domestic; family history negative. Personal history: First menstruated at thirteen. Had an attack of gonorrhœa four weeks previous to admission to the hospital. Examination revealed tenderness over both tubes with some enlargement.

Operation March 26 at 10 A. M. Incision about two inches in length. Tubes and ovaries on both sides found enlarged and congested. Slight adhesions. Both removed. No flushing or sponging of cavity. Wound closed with silk-worm-gut. Time of operation, twenty minutes.

Neither temperature nor pulse ever went above 100. Three stitch-abscesses formed during convalescence, but yielded readily to treatment. Patient left her bed on twenty-first day in good condition.

Case III.— Herniotomy. Diagnosis: Ventral hernia. Admitted to Allegheny General Hospital, March 12, 1892. Mary D., aged 27. Married. Domestic. Family history negative.

Personal history:—According to her own statement, had right ovary and tube removed, with nine inches of intestine, in Philadelphia, in the spring of '89, and in '91 at the same place, had been operated on for hernia, result of first operation. Latter operation was unsuccessful.

Examination revealed protrusions of intestine at various points on the abdomen. The patient extremely fat and flabby. Fasciæ atrophied and retracted.

March 26, 11 A. M. Abdomen including peritoneum laid open. Edges of retracted fascia secured with buried silk-worm-gut sutures. Superficial tissue closed with continuous silk-worm-gut suture. Wound healed by first intention, patient discharged on 21st day. Buried sutures afterward suppurated, yielded to bichloride irrigation, and the wound is now in good condition. The hernia at the point operated upon, is entirely reduced—a large protrusion still exists, however, above the point operated upon, which it is the intention of the operator to attempt to close at a subsequent operation.

Case IV.—Double salpingo-oöphorectomy. Diagnosis: Double gonorrhœal pyosalpinx. Admitted to Allegheny General Hospital, March 28, 1892. Operated March 26th, at 10 A. M. Incision about two inches in length. Tubes and ovaries on both sides found enlarged and congested. Slight adhesions. Both removed. No flushing or sponging of cavity. Wound closed with silk-worm gut. Time of operation, twenty minutes.

Operation March 30, 1892, at 2 P. M. After the abdomen was opened the greatest difficulty was experienced in loosening adhesions sufficiently to expose the uterus. This was finally accomplished. The adhesions were excessively dense and the hæmorrhage following their separation profuse. The right tube and ovary were removed first; they were embedded in a solid mass of adhesions which were so firm that they could scarcely be torn apart. After the greatest difficulty they were torn off. A similar condition was found to exist on the left side, but the adhesions if anything were more dense. The ovary was removed and what appeared to be the remains of the tube. Hæmorrhage was very severe but was finally controlled. A drainage tube was inserted and the abdomen flushed and closed. Time of operation forty-five minutes. At midnight temperature was 99°, pulse 104. The drain tube was exhausted at 8 P. M., and f℥iss bloody water removed. Temperature next morning was normal, pulse 108. Tube being empty was removed at 3 P. M. Pulse same evening 108, temperature 99⅘.° About this time the patient became maniacally hysterical. Tossed and fumed, sang ridiculous jargon, etc. Her abdomen became distended, vomiting set in, and after two days of raving which finally became true delirium she became exhausted and died. Temperature at highest point was 100⅘ °F.

The post-mortem revealed a violent peritonitis with small quantity of pus in the pelvis. Died April 2, 4.30 P. M.

Case V. Double oöphorectomy and anterior fixation of uterus. Diagnosis: Procidentia uteri, prolapsed ovaries with chronic ovaritis and salpingitis. Mrs. D., aged 26, married. Admitted to the hospital sometime during February and awaiting operation at time the operator

came on duty (March 26,'92.) Family history, negative. Personal history.—Gave birth to one child which was "still born" probably from the use of instruments. Her pelvis was found to be badly deformed (kypho-scoliosis). At the delivery of this child the cervix and perineum were both severely lacerated. The latter into the rectum. She had as a result procidentia, and coccyodynia with frightful erosion of uterus. An operation was done by a member of the hospital staff who succeeded in closing the perineum. This operation did not affect the procidentia, however, which returned, the uterus again becoming eroded. Treatment with pessaries was tried but only increased the discomfort.

On examination March 36, the ovaries were found prolapsed and tender and a laparotomy was consequently determined upon.

Operation March 31. Ovaries and tubes found enlarged and congested and removed. Uterus fixed to lower angle of abdominal wound by two buried silk sutures. Wound closed with silk. Temperature rose to 101⅘° on fourth day; also an erratic rise on fifteenth day to 103⅗°. Pulse, however, never went above 100. Some stitch abscesses formed and buried sutures came to surface and were removed. Left the hospital May 26 completely cured and in perfect health.

Case VI. Double oöphorectomy. Diagnosis: Chronic salpingitis, ovaritis and pelvic peritonitis. Mrs. P.; aged 29, married. Family history: One aunt died of pelvic cancer. Operation April 26. Tubes and ovaries on both sides enlarged. Looked somewhat suspicious of malignancy. Time of operation 55 minutes. Recovered, convalescence uninterrupted.

Case VII. Ovariotomy. Diagnosis: Multilocular cyst of right ovary. Left ovary diseased. Admitted to Allegheny General Hospital, May 3rd, 1892. Miss M., aged 20. Family history. Patient, a sister of Mrs. P.; operation May 6. Small cyst of right ovary, left ovary cystic. Time of operation 20 minutes Recovered, convalescence uneventful.

Case VIII. Oöphorectomy. Diagnosis: Multilocular cyst. Admitted to hospital May 5. Mrs. W., age 45. No history. Sixteen pound multilocular cyst, pedicle five inches broad and tied in sections. Recovered, convalescence uneventful.

Case IX. Double oöphorectomy. Diagnosis: Chronic ovaritis. Admitted to hospital May 6. Mrs. C. aged 26. No children. Operation May 7. Ovaries as large as a hen's egg. Both removed. Sat up on twelfth day, left hospital on 19th day.

Case X. Double salpingo-oöphorectomy. Diagnosis: Chronic salpingitis and ovaritis. Admitted to hospital May 24, 1892. Miss H, aged 29. Operation for lacerated perineum and cervix performed in spring of 1890. No relief. Operation May 28, both ovaries cystic and large and both tubes inflamed. Highest temperature 100⅘°. Pulse 90. Recovered. Sat up on 14th day, uneventful convalescence.

Other reports will follow from time to time.

ARISTOL AND EUROPHEN.

By DR. A. EICHLER,

PHYSICIAN TO ST. JOSEPH'S HOSPITAL, SAN FRANCISCO, CAL.

When antiseptic methods were first introduced to the notice of the medical profession, there was but little choice among the agents useful to secure complete antisepsis. Carbolic acid and iodoform were about the only ones in extensive use; objections regarding their toxic faculties and still more regarding their odor were barely considered, although often mentioned. Since progressive chemists, however, have furnished us with almost countless other antiseptic agents, and since carbolic acid has been largely superseded by the bichloride of mercury, those objections, which, as already stated, were hardly noticed in former days, have continually grown in magnitude and are now viewed with such seriousness, that the antiseptic which now wants to achieve distinction and success, must satisfy us not only regarding its antiseptic virtue, but also regarding odor and innocuousness.

As iodoform may be called principally an iodine compound, and as its germicidal action practically rests upon the iodine, it was but natural that chemists should, above all, try to form other compounds of iodine, which should possess the advantages of iodoform without its disagreeable features. They succeeded in giving us quite a number of such compounds, which,

however, never rose to the popularity of their congener. The first compound succeeding in a larger measure than all others previously offered was aristol, which was first presented about two years ago. It is composed of iodine and thymol; chemically speaking, it is a di-thymol-di-iodide, obtained in the form of a brownish red precipitate by treatment a solution of iodine and iodide of potassium with an aqueous solution of thymol and caustic soda. Aristol is insoluble in water or glycerine; in alcohol it is almost insoluble, while in ether or chloroform it dissolves very readily. If alcohol is added to an ethereal solution, aristol will be precipitated. It is also very soluble in fatty oils. Olive or almond oil are the oils most commonly used for this purpose. Oily solutions should never be made by heat, as this would produce chemical changes. In its dry state aristol is of a brick red color, which it also imparts to solutions. It decomposes on exposure to heat or light; this decomposition may be readily recognized by the change in color. It should always be kept in a cool place in colored bottles, amber color to be preferred. Its odor is but slight and not at all disagreeable. It adheres readily to the skin, thus adapting it for application in powder form. It is not toxic, and is in this respect decidedly superior to iodoform. If it was toxic, iodine could be detected in the urine of patients to whom it was applied; repeated examinations, however, by means of the starch test, have given negative results. In cases, where iodoform, having produced constitutional disturbances, was replaced by aristol, no unpleasant effects were noticed. Aristol can thus be safely applied to large surfaces.

In practice aristol has been found very useful in diseases of the skin, in which it proves quite effective without producing stains; it is prescribed in much the same manner as iodoform. It may be applied in its pure state as a powder or its strength can be reduced by powdered starch; it can also be made into a paste with starch and it is thus shown, that aristol contains no free iodine and is a stable compound. As it is soluble in ether, it may be added to collodion in varying strength and then applied with a camels-hair brush. The usual strength of such applications is 1 part of aristol in 10 of the vehicle. For ointments, lanoline or petrolatum can be used as a base to contain from 5 to 20 per cent. of aristol. Suppositories, for rectal, vaginal or urethral disease contain usually from 1 to 5 grains of the active ingredient; heat must be avoided in their preparation. It should also be mentioned, that substances possessing strong chemical affinity for iodine and thus decomposing the compound, should not be combined with aristol.

Besides its successful employment in affections of the skin, aristol has also been much used in chronic ulcers, syphilitic lesions, in short in all those cases, where iodoform has been formerly prescribed internally it has been employed very little. Iodoform, however, has also never been found efficacious when internally given.

When aristol was introduced it was also reported that similar compounds might be obtained by replacing the thymol with resorcin or salicylic acid; neither of these combinations have ever been presented in commerce. Instead of them another rival has arisen, in which a cresolate is substituted for the thymol, its commercial name being europhen; this is a typical example of what modern chemistry can accomplish in the nature of antiseptic compounds. It is formed by the action of iodine on isobutylorthocresol, in presence of alkalies. It exists as a fine amorphous, yellow powder, insoluble in water, but very readily so in alcohol, ether, chloroform or fatty oils, the latter taking up almost 25 per cent. Its percentage of iodine in combination is almost 28 per cent. It is more adherent to the skin than iodoform; it is very bulky, so that a small amount by weight will cover quite a large surface, a fact which constitutes quite a saving in expense. It is supposed to be 5 times lighter than iodoform. Its odor is agreeable, actually quite aromatic. Its action is similar to iodoform, depending on the gradual liberation of minimal quantities of iodine. While europhen is a definite chemical compound in its dry state, it begins in presence of moisture at a degree of heat equal to body heat, to liberate iodine, on which its antiseptic action depends; as this process proceeds gradually and as the iodine combines with the albuminoid constitutents of the body, thus rendering absorption very slow, it is almost innocuous. When alkalies are present, the liberation of free iodine is accelerated. Its solubility in oil allows its application in hypodermic medication.

As europhen is thus like iodoform in its physical properties it is only to be expected that their therapeutic indications should be similar also. Owing to its comparative recent introduction, reports regarding its activity are rather few, those published so far, however, show that the remedy may be confidently prescribed.

One of its chief applications, if it is supposed to supersede iodoform must necessarily be to venereal diseases. In contradistinction to other similar agents europhen has proved quite satisfactory. In soft chancre it promotes healing rapidly; as it is especially in this affection that patients object to the odor of iodoform it is quite probable that europhen will be universally adopted as the remedy. An ointment containing europhen 15 grs. to vaseline or lanoline ½ oz will be an application of suitable strength. It may also be used as an internal remedy in constitutional syphilis, instead of other iodine preparations and it can also be injected hypodermically for this purpose. One should then begin with a very small dose, ⅛ of a grain and increase slowly to 1 or 2 grains; when the dose is increased too rapidly iodism in its usual form may manifest itself. For the various syphilitic eruptions it can be applied in the form of an ointment.

In cases of non-syphilitic affections of the skin, especially the parasitic varieties, it has not proved itself a very active agent. Erysipelas, in its milder forms, is often very much benefited by applications of an europhen ointment of moderate strength. In burns and scalds europhen proves itself an excellent topical remedy. It relieves the pain almost instantaneously, stimulates granulations and leads to the formation of an elastic and firm cicatrix.

It should be applied in ointment form, of about 3 to 5 per cent. strength, with either a vaseline or lanoline base. Another, also very effectual mode of applying it is to first cover the surface of the burn with europhen and then with a 2 per cent. solution in oil; the part affected should be then wrapped in sterilized gauze, which is to be completely saturated with the europhen oil; a piece of oiled silk should be laid over this and fixed permanently, with either a roller-bandage, adhesive strips or a water glass dressing, according to the extent and location of the burn. This makes an ideal dressing, which will not require to be changed often and under which exuberant granulations will be promoted. At the same time, as the oily dressing will not adhere to the wound, there is no danger of tearing off the granulations whenever the wound is dressed, and thus delay healing. Quite severe burns heal by this method in a very short time.

Europhen also is of great service in chronic diseases of the nasal air passages, be they caused by hypertrophy or atrophy. It can be readily applied by a powder atomizer, either alone or in combination with inert dry powders.

In urethral surgery it can be used much like iodoform; gelatine bougies may be impregnated with it.

Europhen is especially indicated in such cases, where a stimulant effect and granulations are desired; in the treatment of chronic ulcers, especially of the indolent order, it will probably be still more used than iodoform has been. Fistulous tracts can, when an operation is not desirable be injected with an ethereal or oily solution thereof and thus be healed.

Considering all, we now possess in aristol and especially in europhen two antiseptic agents, which will answer to all demands heretofore of iodoform. They are somewhat less stable than iodoform, as far as the influence of light is concerned; but this is no serious objection: in antiseptic value they are fully equal to iodoform, equally non-irritating, more agreeable and less toxic, on account of slower absorption. They are useful in all affections where a remedy is required to prevent decomposition and destroy the bacteria of disease.

UMBILICAL VEGETATIONS.

In the treatment of umbilical vegetations, Sevestre (*Rev. Génér. de Clin. et de Therap.*, April 20, 1892) recommends: 1. Every morning the vegetations are covered with tannin finely powdered, this being introduced into all the furrows of the growth by means of a stilette. 2. Apply a padding and a small bandage. 3. On the following days, the crust is removed, a warm bath given, and the application renewed. This treatment is to be continued until a cure is obtained, which generally takes place in the course of 2 weeks at most.

A CASE OF AN OLD RIGHT INGUINAL HERNIA, IRREDUCIBLE; OPERATION FOR SAME.

By JNO. B. CRANDALL, M. D.,
STERLING, ILL.

E. J. H., American, age 74 years; married; occupation, proprietor of a livery stable. Have known Mr. H., for the last twenty years; he has always enjoyed good health with the exception of an epithelium cancer of the right cheek, which was removed some eight years since. Some four years later he had a deep abscess under pectoral muscles, which was treated by deep incision and syringed out with a solution of permanganate of potash.

The patient had been troubled with an old inguinal hernia for years and wore a Hubbard truss. Some four or five years ago I gave him chloroform, and with the assistance of Dr. Keifer we had no trouble in reducing the tumor which was then in the scrotum, by taxis. Has had more or less stomach trouble for the last few years, which has been amenable to treatment.

May 15, 1892, was called just after dinner at 1 o'clock. I found a loop of the ileum in the inguinal canal. He said that he felt something give way in the morning as he was making some exertion to drive some fowls from his dooryard. He was extremely nervous. Dr. Keifer assisted me in attempting to reduce the hernia as before, by taxis. We put him fully under the influence of chloroform and tried all positions and conservative methods with no successful results. We then tried the local application of ether over the seat of the tumor for an hour or more with no success. All of our conservative methods failed to relieve him. After explaining the situation to him and his wife, with their consent we called in extra assistants at 4 P. M., and after rendering all of the instruments and dressings microbe proof, we put him again under the influence of chloroform; cut down upon and pulled out the intestine; removed some old omental adhesions; applied some aseptic wash to the strangulated parts until they appeared to be in a natural state, we then enlarged the abdominal opening and replaced the intestine in the natural bed within the cavity, and closed the wound with a double set of juniper cat-gut sutures; cut short the deep sutures and left them buried. We had no trouble from hæmorrhage. The operation lasted some three-quarters of an hour. We dusted iodoform over the wound and applied iodoform gauze and the ordinary retaining bandage. We then placed the patient in a clean bed, and in a short time he came out from under the influence of the anæsthetic, but had more or less nausea. The operation was performed at four o'clock P. M., three hours after first seeing the case. At ten P. M., we gave him a small hypodermic injection of morphine, which quieted him down for the night. For the next three days we kept him in a passive state, feeding him light broths and to quench thirst, which was not excessive, we gave him Apollinaris water. He felt no pain at the seat of operation but was troubled with nausea, and would eject most of the articles taken into the stomach, and, at times mostly clear bile. This we attributed to the fact that just before the operation he took unknown to us a dose of cathartic pills.

Our next move was to get a natural movement of the bowels. We gave him a solution of epsom salts with the different mineral waters, which were retained for some time, but did not act upon the bowels. We then gave him injections of different mixtures and succeeded in getting a passable movement from the bowels after giving a copious injection of ox gall. The pulse did not run over ninety per minute, and the temperature was normal. He could retain nourishment longer, and the wound gave him no trouble. Ten days after the operation we looked for a speedy recovery, as the incision had healed by first intention. But at the end of the two weeks the stomach symptoms reappeared; he complained of a burning sensation upon taking any fluid. Up to this time there had been no apparent tympanites; all of the pain was located in the stomach. He could not retain food. We tried enemas of beef tea, in order to nourish him by the rectum.

During the last week there was more or less gaseous distension of the stomach and the upper part of small intestines. We were unable to get any further movements of the bowels or keep any amount of nourishment in his stomach for any length of time. He had no fæcal vomit at any time during his sickness. He lingered along in the same way. During the last week we

gave him a hypodermic injection of morphine ⅛ gr. at night, which gave him tolerable rest. He died upon the twenty-first day following the operation.

No post-mortem was allowed.

As to the cause for the persistent stomach trouble, we attributed it to the action of the corroding influence of the bile products open the mucous coating of the stomach, developing latent cancerous lesion; or else to an invagination of the lower part of ileum; or from some bands of plastic material encircling the seat of original stricture. Knowing the patient to be of a cancerous diathesis, we have reason to attribute the stomach trouble to that cause.

OLEUM TEREBINTHINÆ AS A REMEDY FOR CROUP, WITH A REPORT OF FIFTEEN CASES; WITH DISCUSSION.*

By E. W. KELLOGG, M. D.,

MILWAUKEE, WIS.

In consideration of this subject, I wish at the outset to disclaim any originality in suggestion or application of the remedy. I have simply followed the suggestion of others and recorded the results.

Turpentine is an old and well known remedy, and yet, little if any used in croup until within the past two years. It was first suggested by Prof. George in 1886. As it has but a limited internal use, I may perhaps be pardoned for giving some of its physiological actions, as detailed in therapeutical works. It is a stimulant diuretic, antiseptic and expectorant. It arrests fermentation and putrefaction, and is very destructive to all forms of bacteria.

It diffuses into the circulation with great rapidity and is quickly recognized in the breath, sweat and urine.

It is secreted by the skin, kidneys, lungs, bronchial tubes and probably in some measure by the mucous membrane of the trachea and larynx.

The bronchial secretions are considerably increased. Its effect in croup is doubtless due to its local action upon the respiratory tract during its elimination from the system.

*Read before the Milwaukee Medical Society, May 10, 1882.

I am well aware that the diagnosis of any or all of these cases may be called in question and for that reason have omitted two cases in which diagnosis was doubtful. I do not care to be classed among those who see diphtheria or diphtheritic croup in every case in which there is a more or less extensive deposit upon the tonsils, pharynx, nasal surfaces, or larynx; but I do believe in a specific contagious disease called diphtheria, and believe that the majority of cases of so called membraneous croup are in reality diphtheria and should be treated and guarded against as such.

Whatever may flourish in other parts of the city, however much follicular pharyngitis may pass for diphtheria in cleanly houses and among people who observe the most ordinary rules of hygiene, the disease with which we have to deal among the lower classes of foreign population is more than pharyngitis and malignant sore throat. It is a disease that kills by the score as the grim health-office reports will show.

It thrives in uncleanly houses as vermin do and is more common among the lower classes of European immigrants packed in filthy tenements than it is generally supposed to be.

Among these people there are many cases to which no physician is ever called, and these are the invisible causes of many more severe cases of pharyngeal and laryngeal diphtheria.

The ætiology and pathology of croup is shrouded in obscurity both in theory and practice. Until 1858 when diphtheria was prevalent in England, the word croup was confined to an acute disease of the larynx believed to be non-contagious, but much has been done in the past two years towards proving its true cause and rational treatment. Recent investigations tend to show that the cases formerly described as true or membraneous croup were in reality laryngeal diphtheria or in other words, the difference is one of locality and not of exciting cause.

In the majority of these cases membrane was visible in the throat for several days before there were any laryngeal symptoms.

Case I.—The first case was a Polish child two years of age. Had diphtheria for four days when croup developed and she grew rapidly worse.

About forty-eight hours after the laryn-

geal symptoms began Dr. Walbridge was called in consultation. The child was cyanotic. The sternum was strongly retracted with each inspiration.

We informed the father that the only hope for the child was in tracheotomy, and that this would be but a possibility.

He refused to have tracheotomy performed and Dr. Walbridge proposed to try ol. terebinthinæ as an experiment, relating a successful case in which he had previously used it with Dr. Schiller. The child was put on drachm doses every four hours and on the following morning was visibly improved though the laryngeal breathing and crowing cough were still marked. On the following day she was still better and in three days the symptoms of croup had entirely disappeared.

The child remained weak and anæmic for a long time but finally made a complete recovery.

Case II.—German boy four years of age. One of four cases of diphtheria in one room. He developed croup on the fourth or fifth day. His pharynx and nose were filled with false membrane. He with the others had been taking corrosive sublimate and iron in alternate doses. This was continued and in addition ol. terebinthinæ in teaspoonful doses every 2 hours. The cough was easier after a few doses. The retraction of the sternum disappeared. Inspiration became normal and he made a complete recovery.

Case III.—A German girl ten months of age. When first seen she had no visible false membrane. She was in the third stage of croup; cyanotic, greatly depressed. She was given brandy and ol. terebinth. in alternate hourly doses. She died in twelve hours.

Case IV.—A Norwegian boy five years old. Had an attack of diphtheria. Membrane was confined to tonsils and pharynx with a small patch at one corner of the mouth. Developed croup on the second day. Characteristic cough and inspiration. Was gixen oleum terebinth. in drachm doses every 2 hours for four days and nights.

The effects of the drug in this case were especially prompt and efficient. Although the laryngeal symptoms were continuous and severe the effects of each dose could be seen in slower, easier respiration, and a stronger pulse. He made a complete recovery.

Case V.—A Polish child four years of age. Had been under the care of another physician for a week when croup developed. A sister died in the same condition the day before. I saw him. When first seen his respiration was very difficult the sternum falling two inches with each inspiration. He was given drachm doses of oleum terebinthinæ every hour for six hours, then drachm doses every two hours. The following day he complained of some stranguary and the turpentine was given every three hours instead of every two. The stranguary disappeared during the day, and on the following day he was so much improved that the family discharged the doctor. He was on the street three weeks later.

Cases VI and VII.—Polish girls. Two of five cases of diphtheria in one room. The treatment was not carried out. Five successive physicians were called in four days and four of the five cases died including the two with diphtheritic croup.

Case VIII.—German girl four years of age. In the third stage of croup. No membrane was visible. Had only been sick twelve hours. Teaspoonful doses were given every two hours alternating with brandy but there was no agreeable effect and she died within four hours, from suffocation. There was no visible sign of diphtheritic membrane in this case.

Case IX.—Three days later was called to see a brother three years of age and found his throat filled with membrane. Four days later it reached the larynx. He was put upon the same treatment and took eight ounces of turpentine during the next few days. Slowly but steadily all symptoms of croup disappeared and he made a complete recovery.

Case X.—German boy six years of age. Diphtheria followed by croup. He was given drachm doses every two hours for nearly forty-eight hours, but there was no effect. He grew steadily worse and died from suffocation.

Case XI.—A Polish girl two years of age. Four children in the house had diphtheria and her throat was covered with false membrane. When first seen she was breathing with the greatest difficulty, and with each inspiration the sternum was retracted enough to make a hollow the size of a man's fist. The parents positively refused to have further medical attendance as she was expected to die, but they

promised to keep up drachm doses of turpentine every two hours. For four days and nights they gave her a teaspoonful every two hours. She made a slow recovery.

Case XII.—A Polish boy four years old. One sister with diphtheria followed by croup had died within a week. Every inspiration could be heard in any part of the house or out on the walk. His face was cyanotic and his extremities cold. He was given drachm doses every hour during the day and every two hours at night. He grew no worse but the improvement was but slight for two days when he began to improve and made a rapid recovery.

Case XIII.—Was an Irish girl four years of age. Treatment began about twelve hours after laryngeal symptoms developed and was steadily kept up for twenty-four hours but with no benefit. She died from exhaustion.

Case XIV.—German boy two years old. Diphtheria for six days followed by croup. Drachm doses were begun early and given regularly but there was no visible effect. He died in about forty hours.

Case XV.—Polish child one year old. Diphtheria followed by croup. Strong retraction of the sternum, crowing cough, and difficult respiration. He was given half drachm doses every two hours and improved from the beginning. The laryngeal symptoms disappeared in three days and he recovered.

To recapitulate. Of the fifteen cases, eight recovered and seven died. In all of the eight recoveries croup was the sequel of diphtheria of the pharynx.

Of the seven fatal cases two were not given the treatment, in two others there was no visible diphtheritic membrane, in the three remaining fatal cases, croup was the sequel of diphtheria of the pharynx

In but one case was there any disagreeable effect from the remedy, and that was a temporary stranguary when 15 drachms were given in 24 hours to a boy four years of age.

In all cases it was given in milk.

In no case was it rejected after it was once past the epiglottis.

It must be remembered that they were cases of a disease of which ninety per cent. die.

DISCUSSION.

Dr. French: I am very glad that a remedy has been found that will hit what is termed diphtheritic croup, because I have generally bid such cases good-bye as soon as I have heard that crowing cough. I would like to ask in respect to the use of this turpentine, have you given a whole teaspoonful to a child a year old?

Dr. Kellogg: Yes, sir.

Dr. French: Did it have any effect on the bowels?

Dr. Kellogg: No, sir.

Dr. French: It is hard work to give six drops to an adult and have them keep it down. I would like to ask another thing: What effect has it upon the other membranes outside of the larynx?

Dr. Kellogg: I could not see any effect.

Dr. French: Hence it would seem to me that it is somewhat peculiar in its action. It would seem that if it had an action in stopping the formation of a membrane of the larynx or stopping the swelling of the larynx, at least that it should produce the self-same effect on the other membranes; but Dr. Kellogg, do you think that all cases of croup that come under your hands are diphtheritic, don't you believe that there is such a thing as a true membraneous croup from a catarrhal difficulty?

Dr. Kellogg: There may be, but I believe the majority of them are diphtheritic.

Dr. Walbridge: I only want to ask one question. I don't know whether I understood the doctor properly in reference to two of his cases that are included in those fifteen. As I understood him in the recapitulation, in two cases the treatment was not carried out.

Dr. Kellogg: Yes, sir.

Dr. Walbridge: Then it seems to me that a report of thirteen cases would be much more appropriate and much more accurate, and that would make the statistics very much better; and in fact I do not think those two cases belong with the cases treated by the method suggested.

Dr. Kellogg: The children only took two doses. Dr. Walbridge saw that first case with me. I would like his substantiation of the child's condition.

Dr. Walbridge: Certainly if there ever was a case that looked as though an opening must be made somewhere, either through this membrane or below it to give the child a chance to breathe that was one. The time was very short when that must be done. The retraction of the sternum was very marked and the expiration was

as difficult as inspiration, and as the doctor remarked in relating the case, it seemed as though nothing except intubation or tracheotomy would be of any avail; but having seen a case with Dr. Schiller in which he suggested that we try the turpentine before adopting surgical means, I concluded that that was the last hope, as any surgical operation was not admitted in this case.

Dr. Hayes: I feel very glad to hear that some remedy is found that will help those cases. Some years ago I had some experience in this line; I never saw a case of diphtheritic croup that recovered; I have performed ten cases of tracheotomy and every one of them has died; I have used intubation and corrosive sublimate and never saw a case recover; neither have I heard of any case in the county in which I had practiced and where diphtheritic sore throat was prevalent. I never heard of a case that recovered with an operation in my own or any one's practice. So I am glad to hear that a remedy has been found that will offer some hope of recovery in those cases. Certainly it is a desperate condition, and my experience has been very discouraging.

Dr. Shimonek: I would like to ask the doctor to state what effect turpentine had on the membrane itself?

Dr. Kellogg: It came off in a dissolved condition.

Dr. Shimonek: I have had quite a little experience with tracheotomy and with intubation, but I am sorry to say the patients are all dead. I have had six intubations since I have been in the city and every one of the patients died; I have had seven or eight tracheotomies, but every one of the patients is dead; I have had quite a number where I used turpentine and every one died but one, and that one died from complication. The child expectorated the membrane whole, forming a complete cast of the trachea; the membrane was not reproduced, but there was an immense expectoration of purulent and very offensive matter; the child was thirteen years of age and died. I have used bi-chloride until the gums have become sore and in some cases bloody diarrhœa ensued; with no effect on the membrane.

Dr. Walbridge: Please tell us the dose and frequency of it that you employed.

Dr. Shimonek: One teaspoonful not oftener than every four hours.

Dr. Walbridge: I believe the secret is to give enough turpentine.

Dr. Burgess: Would you give the common turpentine of Merck's?

Dr. Walbridge: Merck's is the best.

Dr. Wurdemann: If my question is in order, I would like some explanation of the term croup. To what are we to apply it; is it a symptom or a disease? It seems to me I have seen some cases of simple laryngitis in children in which there are unmistakable croupy symptoms, that is to say stridulous breathing. Can we not have croup in simple laryngitis?

Dr. Kellogg: I do not intend to bring forward a cure-all for croup. I know it is a terrible disease, and I have made a practice until we gave this first child turpentine, if I found a child with strong contraction of the sternum, crowing cough and difficult respiration, to tell the family I could not do any more for the child; and I never had a single case, I think, when I was sorry I made that prognosis; but I believe that if enough turpentine is given, that there are cases in which it is of immense benefit. I believe I have sat and watched children die that might have been saved if I had given them enough of the drug; and it does not pay to give it for a few hours and then stop, but give it in large doses and give it continually. In one of those cases I went every morning and expected to find the boy dead when I got there; you could hear his respiration plainly outside of the house, a long drawn inspiration; he was cyanotic, his extremities (both hands and feet) were cold; his heart was weak; but he was kept on turpentine for between three and four days before there was very much benefit, and then he made a rapid recovery. The membrane came off in flakes, mixed with saliva and foam.

Dr. French: I have performed tracheotomy and I have performed intubation. I did have one case recover of intubation, a girl of 14; and she got nothing internally but the old mixture of iron and potash. The formation of the membrane seemed to stop as soon as intubation was introduced and never returned; I never saw the membrane afterwards; previous to that, however, I could pick it out of the larynx with the laryngeal mirror; but it formed so fast that I saw it was no use in bothering any longer and I therefore performed intubation.

Society Reports.

STATED MEETING OF THE MEDICO-CHIRURGICAL SOCIETY OF LOUISVILLE.

Stated meeting May 27th, 1892.

The President, Dr. Wm. Cheatham, in the Chair.

DISTURBANCE OF CIRCULATION TREATED WITH STRYCHNINE.

Dr. Turner Anderson:—I wish to call your attention to this patient. He is a teamster and has been doing a good deal of hard work for the last two years or more. The point I want to call especial attention to is the irregularity in the circulation. His health all the time has been quite good; there has been no apparent disturbance of the heart, but recently he has been suffering very much from headache. I thought that possibly the trouble might be central in the brain, but an ophthalmoscopic examination by Dr. J. M. Ray reveals no evidence of a brain lesion, and I have not been able to detect any lesion of the heart. The patient states that he does not use tobacco to excess, smokes probably two or three cigars per week, does not chew at all. Drinks largely of coffee. The very marked disturbance in the circulation has been present for about two months. The only treatment has been strychnia in one-sixtieth grain doses three times per day.

PULSATING TUMOR.

Case No. 2—This little girl about five years ago was struck a blow upon the cheek with a hickory stick, which was followed by a great deal of contusion. I did not see the case at the time. After the swelling, contusion, etc. had passed off it left this pulsating tumor. When I first saw the case about a year ago, I could stop the pulsation of the tumor by pressing the finger upon the blood vessel. There seems to be no change in the form or size of the tumor since the patient first came under my observation, except possibly it is a little larger.

ACQUIRED HYDROCEPHALUS.

Case No. 3—The next case I want to show you is a case of acquired hydrocephalus. This case shows that troubles in families never come singly. A little girl in the family sustained a fracture of the lower extremity of the humerus, then about four weeks ago at the time I was called to attend the case of fracture, this child (the case presented) who had always been perfectly healthy, developed symptoms of cerebral disease, began vomiting, constipation, crying, etc., and the vomiting has continued. The cause of the trouble is intracranial effusion, and is simply a result of meningitis that is chronic in character and comes under that head which would be considered acquired hydrocephalus. I have watched the progress of the case, and it is one of considerable interest to me.

LACERATED CERVIX.

Case No. 4—The next case I will show you is a woman upon whom I operated on the tenth of April last for lacerated cervix. The history of the case is that she was married in November, 1890; about six or seven months later she had premature labor—a very serious, hard labor—and did not get up afterward with any degree of satisfaction. In a short time she was able to be about the house, but did not regain her health. Four months after the miscarriage, laceration of the cervix was diagnosticated and an operation performed by her attending physician for its relief, which however was unsuccessful. She then took to her bed three weeks after that and remained in bed from that time until the tenth of April when I performed this operation for laceration of the cervix. It was a unilateral laceration and there was a great deal cicatrical tissue shown in the angle of the tear; her symptoms were of the gravest kind. She suffered from serious reflex symptoms, among others great disturbance of respiration. She had suffered so much from disturbed circulation, respiration, and was so greatly depressed that a profound impression was being made upon the nervous system, and she was losing her memory; it was thought that she was losing her mind. She was greatly depressed, not being able to get out of bed at all; had to be carried from bed and placed upon the table for operation. Dr. Roberts was kind enough to come in and look at the operation, and Dr. Pierce administered the anæsthetic. Four silver wire sutures were used and one silk-worm gut. The silver wires were allowed to remain in for three weeks.

The union is solid and everything is as perfect as it could possibly be, gradually one symptom after another having passed off. She has gained very much in flesh, and can now walk about without any trouble. Before the operation there was great difficulty in her co-ordinating powers. Menstruation has been restored, she has now passed one period satisfactorily. The only symptom remaining is a little unsteadiness in her walk, which you will notice.

MYOSITIS OSSIFICANS.

Dr. A. H. Vance: This patient I saw for the first time yesterday. It is a very rare case, and one of a great deal of interest. I take it that it is a genuine case of myositis ossificans; the girl is now seventeen years of age; had acute pain in the muscular system, commencing when she was quite young. I find the ossific change has occurred in the following muscles: Quadriceps extensor, left thigh; biceps and triceps, right arm; both pectoral groups; both latissimus dorsi and the vertical muscles of the back. There is also a bony growth of ossified muscles about the larynx. I have only seen one other case of this kind, and the ossification in that was not nearly so extensive as this. I told this patient if she would come here and allow us to examine her, that we would consult together and try to devise some treatment, either surgical or otherwise to benefit her.

DISCUSSION.

Dr. Wm. Bailey: From the casual examination I gave the young man presented by Dr. Anderson, the heart does not reveal any valvular lesion whatever. I believe the trouble is cerebral. Such conditions occasionally arise from the use of tobacco, but I doubt if his use has been sufficient to cause it. I believe there is no history of rheumatism or endocarditis, and I think the trouble is of nervous origin.

Dr. D. T. Smith: I quite agree with Dr. Bailey as to the nervous origin, but am inclined to doubt that it is central in the cerebro-spinal system. I think that the case will go on gradually to a fatal termination.

Dr. W. O. Roberts: Referring to the case exhibited by Dr. Anderson, the little girl with tumor on the side of her face: We, of course, all recognize this as aneurism; aneurism involving some of the branches of the anterior temporal artery. It is the second case of the kind I have ever seen, the first being that of a railroad engineer who had his head bumped against the window of the cab. I do not remember just how long this case had been in existence before I saw it; pulsation, however, was not nearly so distinct as it is in the case presented by Dr. Anderson. I operated upon the man and he got well without any trouble. I think Dr. Anderson's case will have to be operated upon soon, or it will burst. The tissues over it are getting very thin.

Concerning the other case—that of lacerated cervix—I was fortunate enough to witness the operation, and the woman's condition is now very different from what it was when the operation was performed. At the time the operation was done, she was exceedingly nervous and hysterical. I have never seen such marked results follow an operation for laceration of the cervix. It was a very large tear, the tissues were greatly indurated. Dr. Anderson did the most thorough operation that I have ever seen; the parting of the edges and approximating of the lips of the wound were perfect. He followed the method of leaving the stitches in for a long time. I think a great many cases of failure in this operation are due to the fact that the stitches are removed too early. The best operators are now leaving them in two to three weeks. I think the result in this case is largely due to the length of time the stitches were allowed to remain in.

Dr. Turner Anderson: I will state that recent works on this subject advise that it is better to leave stitches in for at least three weeks. The last stitches are often taken out at the office of the doctor, the patient being sufficiently improved to come to his office. This case has shown excellent results all through, restoring the woman, who was bedridden for nine months, to the care of her house, to her home and friends.

Dr. E. R. Palmer: Referring to the case exhibited by Dr. Vance, I would suggest that the best thing for this woman to do would be to hire out to some circus and exhibit herself as "the ossified woman,"—that would be a phase of Gold cure that I could most heartily indorse. In my opinion no treatment either medical or surgical would be of any benefit.

Dr. W. O. Roberts: It is an exceedingly rare affection. I saw something on the subject not long ago in the *British Medical Journal*; also saw a case about two and a half months ago that presented conditions very much like this, excepting that none of the growths were movable. This condition appeared in both lower extremities and I think in one arm.

Dr. D. T. Smith: The case presented by Dr. Vance is certainly very interesting. In the lower animals we find this condition known as myositis ossificans is not very rare. The Clydesdale and other heavy horses of that character, frequently have bony growths in the muscles of the legs, and I think the cause is some misdirection of the forces in the relation between bone and muscle formation elements, that has not yet been traced up.

Dr. A. M. Vance: I would like to have somebody suggest some treatment, probably it would have to be surgical.

Dr. H. A. Cottell: I have a distinct recollection of attending a show some two years ago in Cincinnati, and among other things they exhibited what they called an ossified man; to all appearances every muscle in this man's voluntary system (leaving out the occular muscles) was in the condition I take it this woman's muscles will be if the process continues. It seems to me that a case of this kind is hopeless, unless we can arrest the progress.

Dr. J. G. Cecil: I would like to ask Dr. Vance the history of this case, that is, how fast it has progressed, etc.

Dr. A. M. Vance: I do not think you could get the correct history. About six months ago while pumping water she experienced pain in the right arm. I suppose some shifting of the muscles caused this and they date the hardening process from this time. The mother, however, says the trouble has existed for a number of years.

ACUTE ASCENDING MYELITIS.

Dr. J. B. Marvin: I will read a short history of a peculiar case, which history was prepared and handed me by a roommate of the patient:

"Mr. R. H. M., aged thirty-two years. After his fifteenth year, was a man of delicate health though he took extremely good care of himself, except that he was a constant drinker of whiskey, but not to excess. When he was about fifteen years of age he was thrown from a horse and sustained an injury which confined him to his bed for a number of weeks, and also caused partial paralysis of the lower extremities. He made a very good recovery from the injury, though co-ordination was never fully re-established. Ever since the injury was received he has at times complained of pains in the small of his back and hips.

About five years ago, an eczema, as he called it, appeared on his body, and, from scratching, he caused a lesion on his leg, which developed into a chronic ulcer, lasting two years and healing finally but with much trouble. Treatment for the ulcer I do not know.

He had had, according to his own statement, two attacks of gonorrhœa, the first five or six years ago; second while attending lectures here during 1891, from which he had not recovered at the time of his death. He came to this city February first, 1892, appearing to be in very good health and continuing so until three days before the final attack of paralysis. During these three days he complained of pain in the small of his back, and of soreness and stiffness of the muscles of his hips and legs with increased loss of co-ordination. On the night of the third day he had a paralytic attack, while asleep, of the lower extremities, and partial paralysis of the upper extremities, which gradually became complete, except sensation. He was able to move his toes for about two days, and could move his fingers for a little longer. He did not lose his speech until about ten hours before death. He lived four days after he was paralyzed. He died from loss of respiration.

His grandfather and two uncles died from paralysis, also one of his aunts. His father and mother are still living. His connections on mother's side were all stout, healthy people, though nearly all died from paralysis. None of his father's people died in that way. His father is a weakly man, and has a chronic sore leg.

I saw him in the morning with history that he had attended lectures the day before, but felt a little dizziness in going up the steps. That night he waked up and could not move his legs. The next morning early I saw him and he had perfect sensation, but loss of motion in both legs, and partial loss of motion in the muscles of the body; still he turned himself on his hips and moved his arms, though they did

not move as freely and easily as normal, it appeared to me. The paralysis rapidly extended, and he complained of a sense of oppression about the chest. His urine was passed normally. At first he had constant desire to pass the fæces, but later lost that feeling. The intellect was perfectly clear, and about all the pain he complained of was a heavy aching sensation about the back, which he thought was due to lying in bed in one position. This is about the history of the case. The paralysis rapidly extended involving the respiratory muscles, and causing death.

I succeeded in getting an autopsy, but was only allowed to take out the cord. Dr. Frank performed the autopsy. In the lower lumbar region the canal was very bloody, there were also under the membranes two or three segments looking like hæmorrhage. After several weeks hardening of the cord sections were made, which upon microscopical examination revealed evidences of meningitis, probably chronic and more recent diffuse myelitis.

This case seemed clinically to be one of Landry's paralysis, though the autopsy proved it to be a case of acute ascending myelitis, but myelitis that is central generally runs a different course from this and is attended with much more phenomena.

HEMIPLEGIA.

Dr. W. L. Rodman: I saw a case this afternoon in which I am in doubt as to the diagnosis, and would like to have some light thrown upon it. I saw the patient who is about fifty-nine years of age, with a physician of Jeffersonville, Ind., about six o'clock this evening, with the following history: A year ago last Febuary I saw the same gentleman two or three times during an attack of hemiplegia of the right side. The hemiplegia was rather complete, but he made a good recovery in the course of two or three months. He has been uninterruptedly well since that time, and it is now nearly a year and a half since he recovered from the attack of hemiplegia. Yesterday morning his wife left him in bed when she got up to go and see about the breakfast; in about half an hour he came into the dining room; she asked him how he was—said there was no particular reason for asking this as he was perfectly well the day before. He stood perfectly still and stared at her, and said that he thought he was going to die after she left him in their room. He was not able to walk, but his wife and daughter helped him to a chair and finally put him to bed. In a short time he had a convulsion which lasted about three minutes, shortly afterward he had a second convulsion; about eleven o'clock he had a very severe attack, it being the third, After this he became comatose, remaining perfectly unconscious for two or three hours. There have been no convulsions since; he could use both arms and both legs to-day perfectly well. He vomited all yesterday and last night; to-day he has not been able to retain anything on his stomach; until about noon when he drank a little mint water. The patient has been out of his head since the severe convulsion; he did not recognize me when I called, although I have known the man very well. He has no heart trouble, and there seemed to be no particular evidence of atheromatous degeneration in the blood vessels. There is no arcus. Left eye was slightly turned inward. Urine was passed freely, a sample of which I brought home and had an examination made, but no albumin was found. The patient had no fever; pulse was 140 per minute when first seen by his physician; it was 80 soft and regular when I saw him.

I would like to have an expression from the members of the Society as to the diagnosis—if there is a clot in his brain, where is it located?

Dr. Wm. Bailey: I have nothing especial except to say that I doubt about there being a clot, else I think from pressure there would have been paralysis somewhere. It may possibly have been simply meningitis. I saw mention made of this case in the daily paper, stating that he had been unusually taxed for days past. The paper gave the amount of work performed by him for the last few days. It would seem to me to be meningitis, notwithstanding there has been no variation of temperature. In Bright's disease we have a low temperature notwithstanding other conditions that would produce fever. Fever is not always an essential element in the symptomatology of inflammation; there may be counteracting influences which prevent the variation of temperature.

Dr. J. B. Marvin: It would seem to me that diagnosis would lie between one of two things. The first attack was probably embolus rather than clot. The sud-

denness with which recovery occurred and the completeness of the recovery would rather indicate to my mind a small embolus instead of clot. The second attack would seem to me to be cerebral congestion rather than meningitis. The suddenness of the attack would in my mind be against the idea of meningitis. I would not be satisfied with a single examination of the urine. Indications are strongly in favor of the kidneys being the seat of the trouble.

Dr. D. T. Smith: I perfectly agree with Dr. Marvin—of course we must all admit that we can only guess at the diagnosis in this case.

Dr. W. L. Rodman: The case is by no means clear to me. I do not agree with Dr. Bailey that it is in all probability meningitis; the attack was too sudden for anything of that kind. Furthermore, the history of the case makes it rather improbable for the attack to have been meningitis. I think the former attack was very likely due to a small clot rather than embolus. I believe that the present attack is either due to congestion as suggested by Dr. Marvin, or possibly to a clot not in the same situation as the former one, because it would produce paralysis, either of motion or sensation. Further examination of the urine will, of course, be made.

LAPAROTOMY.

Dr. A. M. Cartledge: I have a very interesting case to report, it being a little unusual in the way of ovarian trouble: On the fifteenth of March I was called to see a young married woman, twenty-five years of age with about the following history: Three days before that time her sister living in the country had married, and in preparations for the wedding, she (the patient) had done a great deal of work, lifting some very heavy vessels, and various other things. She had suffered from considerable pain in the left side of the pelvis, a bearing down sensation, ever since the wedding occurred. However she came to the city with the wedding party, was put up with some of her relatives, and one night in going down the steps of the stairs she was stricken with severe pain in the lower pelvic region, and was put to bed which was the occasion of my being called to see her. I found her in the greatest pain, all evidences of marked shock, etc. I was at a loss to ascertain the cause of it. Simply had to practice the expectant plan and gave her a little morphine. The next day found her more comfortable; I examined her at this time by the bi-manual method, but could detect nothing excepting that the pelvic structures seemed more or less indurated, and there was great tenderness. She finally became sufficiently well to go to her home in the country. When her menstrual period came on about the fourth or fifth of April, she had a repetition of all this suffering, only it lasted longer; for three or four days she had to be kept under the influence of opiates in order to get any relief. The pain now was principally in the left side. After this menstrual period, she was unable to move in bed, could not turn from one side to the other. I examined her very thoroughly this time and detected an induration to the left of the uterus rather high up. I concluded to treat her in bed and see if there would not be a decided improvemont in another month, or until the next period. This was done, and she was never able to sit up more then fifteen minutes without the pain becoming so severe that she would have to go back to bed. The menstrual period came again and it was simply a repetition of April, again she had to take the opiates in order to control the pain. After the menstrual period the early part of May you could detect by manipulation a hard induration in the left pelvis, there was also intense pain in that region. A laparotomy was performed at the Norton Infirmary about twelve days ago, and we found that the right ovary was entirely on the left side, behind the left ovary, very much swollen, twice the size of the left. Both the right and left tubes were very much enlarged and thickened, and a great deal of serum in the tubes; uterus was sunken and more or less retroverted, also very much engorged. Both appendages were removed. The patient has done well since the operation, sleeping better the first night without an opiate than she had with opiates for several months,

Dr. C. Skinner: I would like to ask Dr. Cartledge if there was any pus.

Dr. A. M. Cartledge: There was no pus. The tubes were very much enlarged, but, I took it, from mal-position.

Dr. C. Skinner: I am inclined to think that the elongation and displacement were caused by hydrosalpinx.

Dr. J. A. Larrabee: I simply rise to ask a question for information. It would seem that the displaced ovary gave rise to all the trouble. I want to ask the surgeon whether it would not have been proper, if it could have been done, to have replaced the ovary without removing it; that is, if that were the cause of the trouble, why would not relief have followed correction of the position of the ovary without its removal?

Dr. A. M. Cartledge: I will say in regard to Dr. Skinner's remark: It is very probable that there was some hydrosalpinx. The tubes were very large, and very long, and quite red in appearance. Probably hydrosalpinx had something to do with the trouble at the beginning. The question asked by Dr. Larabee would suggest itself: I did not think we were justified in doing a conservative operation, trying to replace the ovary on account of the apparent disease. The safest plan was to get rid of the appendages entirely.

SULPHONAL POISONING.

Dr. J. B. Marvin: I would like to ask for information: I saw a case a few days ago, a gentleman who had taken one afternoon and the following morning, in divided doses, two doses the first afternoon, and three the next morning, sleeping pretty well the first night, two-hundred and forty (240) grains of sulphonal. I know very little about this agent, have never given it in larger doses than twenty grains. This man went to sleep but he never woke up any more. I have been able to find out nothing about the toxic effects of this drug, nor the antidotes. I did not see the patient until some time after he had taken the last dose. Found him sleeping very heavily; pulse was normal and I said let him sleep and we will see what will be the result. I did not know at that time the enormous quantity he had taken. He had taken it on his own prescription, telling his wife that it was absolutely harmless, that he could take half an ounce at a dose. I found out afterwards that he had taken this dose. In the evening at six o'clock his pulse was under 100, respiration 32. I could not rouse him from the first, pupil responded readily to light. He would yawn and stretch himself like a man dead asleep, move his hands, lift his head up and turn himself in bed. I said to his wife that he could not die as long as he was in that condition, that we would just await developement. Early the next morning, much to my disappointment, he showed no evidence of coming from under the influence of the drug, pulse quicker, respiration quicker, circulation poor. Still had reflex movements, pupils responded to light drawing legs up in bed, and would still yawn. During the day this became less and less, and the pulse went up to 140 or more. He passed urine freely until an hour or two before he went to sleep. Kidneys seemed to secrete until the last. I drew off about a pint of urine by catheterization. The only treatment was nitroglycerine given hypodermatically.

THE TREATMENT OF TABES DORSALIS BY THE METHOD OF BONUZZI.

In the *Revue de Thèrapeutique Gènèrale et Thermale,* 1892, No. 2, p. 25, we find a clear and concise statement of this method, which it is hoped will yield results as satisfactory as those attributed to suspension, without, however, exposing the patient to the same danger, nor indeed requiring the use of any apparatus whatsoever. The experiments upon the cadaver have shown that the mechanical distention undergone by the spinal cord is three times as great in this method as in suspension. The patient lies upon the back, head maintained in an elevated position by means of a bolster. The lower extremities are flexed upon the body through a semicircle, the knees being placed upon the chest of the patient, the legs being held straight; the operator, seizing the diverging ankles, carries them strongly toward the floor. The result is, that the vertebral column is strongly flexed forward. This position must be attained with care, for it gives rise to backaches and swellings of the posterior aspects of the thighs, due to intra-muscular hæmorrhage. Benedikt reports a case where attacks of syncope and vomiting for many hours, with adynamia for several days, followed this treatment. It also has a greater effect upon respiration and circulation than does suspension; but the distention to which one subjects the trunk and limbs can be readily graduated, and if necessary, it can be immediately terminated. Benedikt reports that the gait of the patients was greatly improved, and the neuralgias markedly and constantly relieved.—*American Journal Medical Science.*

Selected Formulæ.

THE CYANIDE AND TRICYANIDE OF GOLD IN PHTHISIS PULMONALIS.

Dr. Oesterlen (*Pharmaceutische Zeitschrift für Russland; Le Bulletin Médical*, No. 101, 1891) recommends the following formula of the cyanide of gold in the treatment of phthisis:

℞ Cyanide of gold..... cgms. 18.
Chocolate..... gms. 45.

The cyanide of gold presents itself under the form of a yellow powder, insoluble in water, alcohol or ether. The crystals are only recognizable under the microscope. This preparation was proposed forty years ago by Chretien as a remedy for the treatment of pulmonary tuberculosis, scrofulosis and amenorrhœa. Later being forgotten, it recently has been proposed as a therapeutic resource in phthisis. The dose is from four to sixteen milligrammes several times a day. The tricyanide of gold comes in the form of large colorless crystals, which are soluble in water and alcohol. It has also been prescribed recently as a remedy in a phthisis.

SPECIAL TONIC (BELLEVUE HOSPITAL).

℞ Sulph. quinine..... 30 grains.
Tinct. nux vomica.....160 minims.
Tinct. chlor. iron.....160 minims.
Dilute phosphoric acid..... 1 fluid ounce.
Syrup to make..... 4 fluid ounces.
M. Dose, a teaspoonful.

POMADE FOR CERVICAL CYSTITIS IN WOMEN.

℞ Camphorated lanolin.....30 grms.
Ext. belladonna..... 2 grms.
M. Sig.—Introduce, morning and evening, into the vagina on a wad of cotton.

TREATMENT OF LUPUS ERYTHEMATOSUS OF EYELIDS AND FACE.

Brocq (*British Journal of Dermatology*, 1891) recommends in this disease:

℞ Salicylic acid..... ʒss.
Lactic acid..... ʒss.
Resorcin..... gr. xlv.
Zinc oxide.....ʒij.
Vaselin.....ʒxvij.

The following is also usually well borne:

℞ Salicylic acid..... 1 part.
Pyrogallol..... 2 parts.
Vaselin.....20 parts.
This is to be rubbed in at night. During the day the first named may be applied, the two being thus used conjointly.

TONSILLITIS.

Dr. Eloy (*Medicinische Neuigkeiten*, No. 8, 1892) recommends the local application of salol in the treatment of tonsillitis, and as follows:

℞ Salol.....gms. 2 (grs. xxx).
Alcohol, q. s., ad. sol.
Glycerine.....gms. 40 (fl. ʒjss).

For the painfulness in swallowing, gargle with:

℞ Cocaine hydrochlorate.....mgm. 1
(gr. 1-64th).
Glycerine.....gms. 10.
(ʒijss).

Or use Huchard's mixture:

℞ Bromide of potash.....gms. 5.
(ʒj¼).
Cocaine hydrochlorate..... mgms. 5.
(gr. ⅓)
Glycerine..... } āā gms. 10.
Peppermint water..... } (ʒijss).

TREATMENT OF ASTHMA.

℞ Potassium iodide.
Lobelia tincture.
Senega tincture..... āā 2.00 grms.
Opium extract..... 0.02 grm.
Distilled water.....180.00 grms.
Sig.—Tablespoonful, mornings and evenings, in a wineglassful of water.

—Huchard, *Revue Générale de Clinique et de Thérapeutique; Merck's Bull.*

ANODYNE LINIMENT.

℞ Camphor.....120 grains.
Chloral.....120 grains.
Chloroform..... 120 minims.
Ether.....120 minims.
Tincture opium..... 60 minims.
Oil sassafras..... 60 minims.
Soap liniment to make..... 16 fluid ounces.

FOR DYSPEPSIA.

For pain in the chest which comes on half an hour or an hour after food, take the following:
Take of

℞ Tincture of nux vomica.....10 drops.
Acid hydrochloric dilute.....10 drops.
Chloroform water..... ½ ounce.
Mix, and take immediately after meals.

LOOMIS' TONIC.

℞ Sulph. quinine..... 15 grains.
Tinct. chlor. iron.....120 minims.
Spirit chloroform.....180 minims.
Water..... 1 fluid ounce.
Glycerin to make..... 2 fluid ounces.—M.
Dose, a teaspoonful.

DANDRUFF.

Dr. Stephen (*Lo Sperimentale*, No. 18, 1891) praises the following:

℞ Resorcin..... } āā gms. 10.
Ol. olivar..... }
Ether..... }
Alcohol rectificat..... gms. 200.
Shake well and apply with a stout brush.

PURGATIVE INJECTION.

Dr. Porter (*Le Progrès Médical*, No. 50, 1891) recommends the following:

℞ Extr. bil. bovis.....gms. 25.
Glycerin.....gms. 100.
Ol ricin.....gms. 50.
Aquæ.....gms. 25.
Mix with one pint of warm soap and water.

DIABETES.

The following mixture is praised by Vigier:

℞ Lithii carbonat.....30 grains.
Sodii arseniat..... 1 grain.
Ext. gentianæ.....15 grains.
M. et div. in caps. no. xx.
Sig.—Take one capsule morning and evening.

INJECTION FOR OZÆNA.

The following is Sidlo's formula:

℞ Potass. chlorati..... 6.
Glycerini..... 30.
Aquæ destillat.....300.
M. To be injected, several times daily, in ozæna. Small rolls of cotton wet with a solution of glycerin (1 in 3) are also introduced thrice daily, and allowed to remain for one hour each time.

PRURITUS ANI.

Dr. Joseph M. Matthews has obtained excellent results from:

℞ Benz. oxide zinc oint.
Campho-phénique.....āā ℥ss.
M. Apply as often as necessary.

The campho-phénique may likewise be used pure, without detriment to skin or mucous membrane.

ECZEMA OF SCALP.

In inveterate eczema of the scalp Dr. Bedford Brown (*Maryland Med. Jour.*) found the following lotion by far the most certain:

℞ Ol. ricini.....f℥iv.
Bay rum.....f℥ij.
Acid salicyl.....℥ij.
Resorcine.....℥i.
Quinine sulphat.....grs. x.
This very active parasiticide is to be applied over the scalp night and morning and rubbed into the skin. He believes that perseverance in the use of this remedy will not only relieve most cases of this kind but will promote the growth of the hair.

OINTMENT FOR HÆMORRHOIDS.

℞ Hydrochlorate cocaine.....gr. xvj.
Sulphate of morphine.....gr. v.
Sulphate of atropine.....gr. iv.
Powdered tannin.....gr. xvj.
Vaseline.....℥j.
Essence of rose, q. s.
Make an ointment and apply to the affected parts after each movement from the bowels. It is necessary to have the discharges of soft consistency.
—*Journal American Medical Association.*

FOR THE PAROXYSM OF ASTHMA.

℞ Morphinæ sulphat.....gr. ¼.
Atropinæ sulphat.....
Nitro-glycerini..... āā gr. $\frac{1}{100}$—M.
Sig.—Add to sufficient sterile distilled water, and inject hypodermatically at the onset of the paroxysm.

REMOVAL OF EXTRAUTERINE FŒTUS FIVE MONTHS AFTER TERM: RECOVERY.

Delaissement (*Annales dé Gynec. et d' Obstèt.*, May, 1892) operated on May 7th, 1889, on a single woman, aged 20, who had become pregnant after the cessation of the menses in Febuary, 1888. On December 13th, 1888, labor pains came on two days later the fœtal movements; were plainly distinguished, and the heart sounds were audible. The cervix was like that of a virgin. By December 17th the pains had ceased. Afterwards the catamenia returned, the fœtal cyst remained as a tumor, resembling a large fibroid, and extending to the left hypochondrium. The tumor did not press down into the pelvis, the uterus was distinct and pressed forwards, and to the left. On May 7th the operation was performed. The fœtal cyst was not adherent to the abdominal walls; there was a fluctuating area on its upper part. In order to cut off all communication with the peritoneal cavity, sutures were passed through the cyst wall on each side of the wound. A brownish fluid escaped through the two uppermost suture tracts. The cyst was opened between the sutures. The fœtus lay aransversely, with the head to the left. The placenta, very thick, was attached anteroinferiorly; it was as tough as though macerated in alcohol, and was not vascular. The cavity of the cyst was washed out with hot water containing chloroform, and dresesd with carboltzed gauze; a large drainage tube was inserted. High temperature, with alarming symptoms, followed, and did not abate until the fifth day, when the placenta began to separate. Delaissement believes that the fever was due to infection of the peritoneum by the two upper sutures, and observes that sutures so applied should be made to pass along the substance of the fœtal cyst wall, and never across the cavity of the cyst. By June 5th all the placenta had come away. A year after the operation the patient was seen by Delaissement: She was in excellent health, and the catamenia were regular. There was a slight hernial protrusion inferiorly.—*British Medical Journal.*

THE

MEDICAL and SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

DIRECT COMMUNICATIONS TO
P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor.
(Professor of Physiology, University of Penna.)

BUSINESS OFFICES:
29 to 35 North Tenth Street, Cor. Filbert.

EDITORIAL OFFICE:
Southeast Cor. 36th and Woodland Ave.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00

REMITTANCES should be made payable to THE MEDICAL AND SURGICAL REPORTER, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

—o—

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates).... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt "**The Medical and Surgical Reporter**" and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts..... $1.50 each.
Bovine Points or Quills..... 1.00 a doz.
Humanized Crusts..... 1.00 small.
Humanized Crusts..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

☞Please accompany orders with the money, and address all communications to

Leading Articles.

ETHER VERSUS CHLOROFORM AS AN ANÆSTHETIC.

The subject of this article is truly a hackneyed one, yet one in which every practitioner of medicine must always feel a keen interest. It has not been long since every medical periodical both in this country and abroad was teeming with articles on the merits and demerits of chloroform—this unusual and general interest having been excited by the labors of the Hyderabad Chloroform Commission under the able leadership of Dr. Lauder Brunton, of England.

The preference given to ether in this country and to chloroform in Germany are acknowledged facts. The position occupied by surgeons in other countries has been varying, each of these great anæsthetics having in turn been credited with the greater advantages outweighing their disadvantages. Both, unfortunately, have their disadvantages and dangers, but until the ideal anæsthetic has been discovered we must be content with what must prove the "lesser evil."

Poignant didactic arguments, based upon experimental researches, are always both interesting and instructive; and, therefore, a brief consideration of one of the most thorough and recent contributions on this subject may not be without good. The writer, Professor Julliard, of Geneva, published his paper in a recent number of the *Revue Medicale de la Suisse Romande*. "Ether," says Julliard, "is almost exclusively used by the surgeons of the United States and of Lyons, who never cease in extolling an anæsthetic so much less dangerous than chloroform."

The statistics gathered show a ratio of one death in every 3,258 cases of chloroformization, and one death in every 14,987 cases of etherization. The innocuity of ether—innocuity compared with that of chloroform—is incontestable, and all that

hinders its universal adoption as an anæsthetic are the several inconveniences that accompany or follow its use. In order to justly weigh the merits and demerits of ether, Julliard discusses these singly and without bias, and the result is markedly in favor of ether.

What are the disadvantages of ether ?

First, it is disagreeable to the patient. The inhalation of choloform is far more acceptable. Yet who, exclaims Julliard, would be guided by a question merely of pleasantness when it means the employment of a drug four or five times more dangerous to life? There is undoubted force in this argument, but the nausea, retching and vomiting so frequently induced by ether must still be regarded as a serious objection, capable of not only delaying the operation but also of weakening the patient, and not infrequently jeopardizing an ultimate good reaction from the operation.

Second, there is more difficulty in the administration of ether, and generally a more or less complicated apparatus is required. This objection, according to Julliard, is really without foundation. In truth, while ether inhalers in vogue are generally more complicated than the simple chloroform inhaler, yet their comparative complexity neither renders them awkward nor cumbersome in the hands of an experienced anæsthetizer. But apart from this, any complicated apparatus can be dispensed with.

Third, ether is less active than chloroform, and its action is considerably slower. While acknowledging this to be a fact, Julliard does not regard it as an objection, but rather as an advantage. In the first place, he has observed that even ether induces anæsthesia within five or six minutes in the majority of cases—surely satisfactorily rapid. Again, in such cases in which anæsthesia is not as quickly induced, naturally a larger quantity of the anæsthetic would have to be used, be it ether or chloroform, and in this event the use of the more slowly acting and less powerful poison should surely be given the preference.

Fourth, another objection to ether that may be raised, and which has frequently been offered by the supporters of chloroform, is that the complete insensibility obtained by chloroform cannot be produced by ether. The experiences of Julliard and other writers, however, fail to confirm this objection. On the contrary they have been able to produce a condition of insensibility equally as profound as with chloroform.

Fifth, it has also been claimed that the period of excitation is longer with ether and occurs more frequently. This has long been regarded by many as a most serious objection, but Julliard's experiments fail to show any appreciable difference in the periods of excitement of the two drugs.

Sixth, an objection to ether is its inflammability. In this respect chloroform has undoubtedly an advantage over ether. Still, if the lights are well placed above the patient, there is nothing to fear when the use of artificial light is demanded. Julliard has also used the thermo-cautery upon the thorax during anæsthetization with ether without harmful results.

Finally, another objection urged against ether is its irritating action upon the mucous membranes; producing cough, salivation, and an increased bronchial secretion. These unpleasant phenomena, while occuring occasionally, are not of a serious nature and may frequently be greatly lessened or entirely overcome by the proper administration of the drug.

The conclusions of the author, based upon fifteen years' experience with chloroform and fourteen years' experience with ether, may be briefly summed up as follows:

First, that ether is far less dangerous than chloroform.

Second, that the anæsthesia produced by ether is equally as complete and profound as that occasioned by chloroform.

Third, that the inconveniences of ether, absent in chloroform, may be greatly lessened by a proper administration of the drug.

Fourth, that the only contraindications for ether are its inflammability, and its action upon the respiratory mucous membranes in cases where these are diseased or are in bad condition.

The mask used by Julliard for the administration of ether resembles the simple chloroform mask with the following modifications: the outer portion is covered with some impermeable cloth, either mackintosh or rubber, to prevent the too rapid evaporation of the drug; it is also sufficiently large to permit of free respiration. The inhaler or mask is 15 centimetres long, 12 wide and 15 deep.

So much for Julliard's experiences and experiments. But he is not alone among Swiss and German surgeons in advocating the use of ether. Among German physicians in particular, who for a long time almost exclusively used chloroform as an anæsthetic, the gradual change of feeling is most marked. Garré, in the *Münch. Med. Wochenschrift*, gives the results of his experiments with both anæsthetics in a large number of cases, and heartily endorses the use of ether as a surgical anæsthetic in preference to chloroform. In 400 surgical cases in which ether was used as an anæsthetic, he observed that in those patients suffering from an organic lesion of the heart the drug was well borne and even exerted a beneficial action upon the affected organ; while in cases of respiratory troubles the irritative properties of ether rendered its use very objectionable. He concludes, therefore, that ether is preferable to chloroform in patients suffering from cardiac troubles; but on the contrary that chloroform is preferable to ether in cases of bronchial catarrh and similar affections. Garré found that anæsthesia occurs on an average in about four minutes, and that about 80cc. are required to maintain anæsthesia for a half an hour.

Dr. Frieter, in a recent issue of the *Deutsche Zeit. für Chirurgie*, also pleads the cause of ether as a general surgical anæsthetic; and Dr. Butter, in the *Archiv. fur Klin. Chirurgie*, speaks most highly of ether as a substitute for chloroform in general surgery.

A great advantage of ether over chloroform, as recently pointed out by these investigators, is the rapidity with which patients recover from the effects of ether as compared with chloroform. Death from anæsthetization syncope, they also claim, will almost be unknown should ether be used instead of chloroform.

Thus an anæsthetic, the superior merits of which have long been recognized by the surgeons in this country, is now only gradually asserting its claims among our professional brethren abroad.

ACETONÆMIA.

From a clinical and experimental study of the subject, Boesi (*Riv. di clin. et terap. Rev. Intérn. de Bibliog. Med.*, April 25, 1892) has drawn the following conclusions: 1. Acetonæmia exists in the physiological state, as has been sustained by Jacksh, Baginski, and others, its amount fluctuating from 12 to 15 milligrammes. It does not become a pathological process until it has passed this quantity. 2. An experimental acetonaemia can be produced by the administration of agents which especially destroy the blood, such as pyrodine. A lack of oxygen in the blood is an auto-intoxicating cause of acetonæmia. Pathologically, the condition is observed in malarial anæmia, in catarrhal icterus, in the febrile acetonæmic state whose cause resides in the destruction of the blood-cells and the albumin of the tissues themselves. 3. The acetonæmia of intestinal origin is not dangerous, but it has of late been exaggerated. The diminution in the alkalinity of the blood is not the cause of acetonæmia, but a phenomenon belonging to the order of the auto-intoxications.

Book Reviews.

DISEASES OF THE EYE. A Hand-book of Ophthalmic Practice for Students and Practitioners. By G. E. de Schweinitz, M. D., Professor of Diseases of the Eye in the Philadelphia Polyclinic; Lecturer on Medical Ophthalmology in the University of Pennsylvania; Ophthalmic Surgeon to the Philadelphia Hospital, and to the Children's Hospital and Infirmary for Nervous Diseases. 216 illustrations and 2 chromolithograph plates. Philadelphia: W. B. Saunders, 1892.

No one who is at all interested in the study of ophthalmology can fail to appreciate this latest contribution to the standard text-books on this subject. Close observation, a keen sense of appreciation, an association with the best minds engaged in the study of ophthalmology in Philadelphia, a rich practical experience, together with careful study, have eminently fitted the author of this admirable work to give us the best American text-book that has been published in this special field of medical science.

A critical reading aided by a comparison with other standard works of the kind convinces us that it is destined to fill a prominent place among the standard works upon diseases of the eye. It is pre-eminently a book for those wishing a clear yet comprehensive and full knowledge of the fundamental truths which underlie and govern the practice of ophthalmology. The author has kept well in view his purpose in preparing the book.

It is seldom that we find greater clearness of expression, combined with a graceful and pleasing style, than is here shown in the elucidation of general optical principles, methods of examination, symptomatology and diagnosis. Everywhere the text has been systematically arranged; this is particularly true of the description of the symptom-groups, which include under minor headings the variations caused by the different grades or types of the same pathological state. The section devoted to the consideration of general optical principles is excellently adapted for the use of students; being clear, concise and finely illustrated by appropriate diagrams.

The chapter upon refraction is contributed by James Wallace, M. D., and it is of such excellence that it creates a wish that it had been expedient to make it more extended. The author's long experience in the eye department of the University of Pennsylvania Hospital is itself evidence that this portion of the work has been in competent hands.

The section upon retinoscopy was contributed by another able ophthalmologist, Dr. Edward Jackson, Professor of Ophthalmology in the Philadelphia Polyclinic. It is needless to say that this part of the book is also exceedingly well done.

Taken together we think that with such a clear and most excellent exposition of the principles of ophthalmology, written by such entirely competent men, there will be little need for European text-books upon this subject; for while symptomatology, diagnosis, and technique of the examination of the eyes have received the largest consideration, neither pathology nor treatment have been neglected. It justly may be pronounced a complete statement of the essential facts of ophthalmology.

Periscope.

THERAPEUTICS.

FACIAL NEURALGIA.

Dr. Stewart thinks hypodermic injections of ergotin in facial neuralgia to be superior to aconite or gelsemium. Generally one injection is sufficient, but sometimes two or even three may become necessary.—*The Medic. Anal. Gaceta Medica Catalana,* 10, 1890.

MICROCIDINE IN URINARY ANTISEPSIS.

Although there are many antiseptic remedies useful in the treatment of disorders of the urinary tract, Mabboux (*Lyon Méd.*, April 3, 1892) prefers, in the application of direct and indirect antisepsis, the employment of *microcidine*, which, as is well known, is composed of naphtol and caustic soda. The solution of this remedy is, according to the author, sufficiently efficacious for all manner of surgical antisepsis. It does not produce pain in the urethra nor in the bladder. In cases of cystitis, washing with microcidine are more advantageous than those in which boric acid is employed. The medicament is easily tolerated by the stomach, in doses of 2 grammes a day, producing good results. In direct antisepsis microcidine is not superior to salol, but it may be employed in patients suffering from albuminuria and other diseases of the kidneys, without causing untoward effects.

POISONING BY ATRACTYLIS GUMMIFORA.

This plant belongs to the order of the Compositæ, and is supposed to be of an edible nature. It has bitter and narcotic properties resembling those of poisonous mushrooms, and, like digitalis, is said to possess cardio-vascular powers. Two fatal cases of poisoning by atractylis are reported by Courcenet (*Arch. de Med. Milit.*, April, 1892). The symptoms observed were as follows: Pain in the stomach; great, burning thirst; vomiting; profound depression; muscular relaxation; loss of consciousness, and death by coma, but without convulsions. At the autopsy, there were found ecchymosis on the walls of the stomach, and hæmorrhagic foci in the kidneys; the blood was of a dark color and of a liquid consistency; sanguinous stasis in the abdominal viscera, the liver, and the cortical substance of the kidney. There were no lesions of the respiratory organs or of the nerve centres. The author points out the necessity, in medico-legal cases, of looking for the poison in the contents of the digestive tract, and especially in those of the stomach and the intestines.

GLYCERINE IN HEPATIC COLIC.

At a meeting of the Paris Academy of Medicine on March 8th (*Sem. Méd.*, March 9th, 1892), Ferrand read a paper on the treatment of hepatic colic by glycerine. The following are his conclusions: (1) Glycerine given by the stomach is absorbed unchanged by means of the lymphatics, especially by those passing between the stomach and the hilum of the liver and the gall bladder. (2) It is a powerful cholagogue and a valuable remedy in hepatic colic. (3) In relatively large doses—20 to 30 grammes—it brings an attack to an end. (4) In small doses—5 to 15 grammes—glycerine taken every day in a little alkaline water prevents fresh attacks. (5) Without being a lithontriptic, glycerine is the remedy *par excellence* for biliary lithiasis.—*Brit. Med. Jour.*

THE DANGER OF COUNTER-IRRITATION IN LOCALISED TUBERCULOSIS.

According to Parrachia Anacleto, counter-irritation in localised tuberculosis is attended with great danger. Miliary tuberculosis spreads so rapidly from one organ to another by way of the veins and lymphatics that any irritation set up at the seat of the primary mischief cannot fail to increase the tendency of the disease to become general. Four cases which have recently come under his notice show this in a remarkable degree. Tuberculosis progresses slowly, but it allows of no violent remedies, and he thinks, until some method of treatment more successful than either the injection of tuberculin, or cantharidate of potash, or the application of blisters has been discovered, the danger of causing general infection by their adoption will still remain.—*Lancet.*

ACTION OF CAMPHORATED OIL.

At a meeting of the Società Lancisiana degli Ospedali di Roma on February 13th (*Gazz. d. Osp.*, March 8th, 1892), L. Taussia stated that he had used camphorated oil with good results in many cases of influenza in which collapse from cardiac paralysis appeared to be imminent, and in pneumonia, typhoid, etc. He gave the drug dissolved in oil of sweet almonds in the strength of 1 to 2, and sometimes 4 to 5 per cent. Essence of peppermint was useful in disguising the taste. Liberal doses (2 to 4 grammes *per diem*) were always given; the remedy was always well borne, and no disagreeable effects were observed. The remedy should be given before the patient is *in extremis*, when an active stimulant and expectorant is required, and when it is not contraindicated by the existence of great cerebral excitement. In cases of pneumonia, bronchopneumonia, and typhoid fever, the drug produced increase of arterial pressure, freer expectoration, and a feeling of physical well-being which lasted a considerable time. Taussia insists that only the best Japanese camphor should be used, the artificial preparation having, according to him, no therapeutic value.—*Brit. Med. Jour.*

PHENACETIN IN GONORRHŒAL RHEUMATISM.

Dr. Rifat (*Norsk Magazin for Lœgevidenskaben*, No. 5, 1891) relies upon phenacetin in large doses when the salicylate of soda, iodide of potash and antipyrin fail. The first day one may give one gramme three times daily, then increase the dose

until six or eight grammes (1½–3 ʒ) are taken in a day. The patient must be watched for signs of poisoning—dyspnœa, cyanosis, vomiting, etc.

A NEW TREATMENT OF ACUTE GONORRHŒA.

Cotes and Slater (*Lancet,* London, February 27, 1892) describes a new treatment for acute gonorrhœa. The patient is first made to micturate, and thus remove as much discharge from the urethra as possible. The endoscope tube, warmed and oiled, is then passed into the urethra, the patient lying on a couch. As a rule, the passage of the instrument gives rise to but slight pain, but occasionally, in sensitive patients, a ten per cent. solution of cocaine, previously injected into the urethra, will be found useful. The urethra is then thoroughly mopped with dry cotton-wool, fixed in a stilet, and examined by the electric light. The exact limit of the inflammation can be clearly seen. It is, as a rule, quite five inches from the meatus; it may be four as early as the third day. The implicated surface is at once to be recognized by its swollen, bright-red appearance as contrasted with the rosy color of the healthy urethra. It is important not to pass the endoscope needlessly far back of the posterior limit of the inflammation, which is usually sharply defined. The diseased membrane should now be carefully mopped again so as to remove every vestige of secretion. A mop of cotton-wool, on a stilet, charged with a solution of nitrate of silver (10 grains to the ounce), should be pushed through the endoscope tube and out the distal end. The tube and the mop are then simultaneously withdrawn. For the two inches of urethra near the meatus a fresh mop is used, so as to completely saturate this part, where the disease commences, and the inflammation is most intense. Patients generally complain of slight pain afterward, which, however, passes away in the course of ten minutes. The patient is recommended to take a hot bath that night and remain in bed the following day. A saline purgative and an alkaline or copaiba mixture are given internally. From four to six times daily the patient should use a simple cleaning injection—say Condy's fluid, (one drachm to the pint). The forty-cases treated in this manner have been cured in a little over twelve days; a few cases had lasted for some days, and some were associated with chordee.

The principal points of this treatment are:

(1) The urethra can be cleansed so that the application comes directly in contact with the diseased membrane.

(2) The extent of diseased surface may be seen.

(3) The remedy is applied when the urethral walls are stretched, so that all furrows are obliterated.

They think that nitrate of silver is the best of all injecting fluids, from the fact that, in the strength of 1 to 2,000, it kills the organisms and produces very little irritation, and at the same time exerts a healing influence on the inflamed membrane.—*Univ. Med. Mag.*

MEDICINE.

INFLUENCE OF STOMACH WASHINGS ON THE ASSIMILATION OF NITROGENOUS ARTICLES OF FOOD.

In a very interesting thesis, J. A. Ouaroff, (*Wratch*, No. 51,1892, *Bull. Gen. de Therap.*, March 30, 1892) discusses this important practical point. The observations were made in five patients; 3 of whom were suffering from chronic catarrh of the stomach, and two with catarrh accompanied with dilatation of the organ. Five other observations were made on healthy individuals. Each experiment lasted 16 days, and comprised 2 periods of 8 days each, one of these *with*, and the other *without* the washings. Upon healthy persons the washings improved the assimilation of the nitrogenous substances in the following proportions: maximum, 3.75 per 100; minimum, 0.47 per 100; medium, 2.21 per 100. In 3 patients the assimilative powers were increased also, in the proportion of 2.79 per 100, for the maximun: 1.67 per hundred for the minimum, and 2.39 per 100 for the medium. In 2 patients the assimilation was diminished; in one, 1.13 per 100; in the other, 1.33 per 100. This diminution depends upon the retention of the liquid in the stomach. According to the author, the washing out of the stomach improves the function of the organ, diminishes

stagnation and fermentation, and increases, reflexly, the activity of the biliary and pancreatic secretions. Under the influence of the treatment, the bodily weight and the forces of the patient increase, showing the favorable action which the stomach washings exercise on nitrogenous assimilation.

HYSTERICAL ARYTHMIC CHOREA.

From an interesting thesis, published this year, by Dettling (*Rev. gener. de Clin. et de Therap.*, April 20, 1892), the following conclusions are drawn: 1. The theory regarding the co-existence and simultaneous development of Sydenham's choreas and hysteria, may hold good in certain cases, but exceptionally so. 2. The hypothesis which makes of common chorea a modification of hysteria, and which is based on very uncertain points, is rejected by the author. 3. The theory admitted by the French observer is that by which hysteria may simulate the arythmic movements of common chorea, producing a pseudo-chorea of a Sydenham type, and which he calls a hysterical arythmic chorea; but there is no such a thing as a Sydenham chorea of a hysterical nature. The hysterical arythmic chorea may, therefore, be placed under the same category as that of the pseudo-scleroses and hysterical pseudotabes. Hysteria may give rise to the production of a quite marked common chorea, but this arythmic chorea is to be differentiated from Sydenham's chorea. Its onset is sudden, and exhibits a variety of hysterical symptoms. Its duration is similarly various; it always gets well, spontaneously often, and frequently relapses if it occur. It ought to be looked upon as a prolonged attack of paroxysmal hysteria. The treatment should be of a tonic nature. Antipyrine has given good results in many cases.

MERCURIAL GASTRO-ENTERITIS.

In an experimental research, P. de Michele (*Rivista Clinica et Terapeutica*, Naples, XIV, No. 2, 1892) has endeavored to determine the nature of the lesions produced in the digestive tract, under the action of mercury, and which of those lesions are the least dangerous. The experiments were made on rabbits, and the modes of administration of the drug were such as are serially pointed out presently. No lesion was observed in the first series of experiments, while in the rest, the drug was found capable of producing a rapid and serious fatty degeneration of the mucous glands: 1. Hypodermatic or parenchymatous injections of calomel, according to the method of Sarenzio. 2. Albuminate or tannate of mercury by the stomach. 3. Injections of the albuminate, according to the formula of Miahle. 4. Internal administration of the protiodide of mercury. 5. Injections of corrosive sublimate. 6. Van Sweiten's solution or simple solution of corrosive sublimate by the stomach.

TEMPORARY DYSPNŒA CAUSED BY A TUMOR OF THE NECK.

The following case is reported by Pergens (*Archivos Internacionales de Rinologia*, No. 14, 1892): A country farm-boy, 16 years of age, had a tumor situated on the superior portion of the right side of the neck. He complained of aphonia every time a current of air struck him, and also of a sensation of constriction in the throat. On examination there was observed a distention of the skin at the superior part of the right side of the neck, and at the maxillary angle about two centimetres from the protuberance of the chin. The laryngeal mirror revealed nothing abnormal. During the condition of aphonia there was no change noticed externally, but in the larynx only the left vocal cord could be seen; the right cord was hidden behind a rounded protuberance, covered by a normal mucous membrane. After a few days, this condition disappeared; the voice came back and the intra-laryngeal swelling was greatly diminished. By an operation, the glands and the hypertropied submaxillary gland were raised. After this, a cure was effected and the symptoms of aphonia never returned. These symptoms were attributed to an inflammatory process, being produced by the action of cold upon the diseased ganglions.

DILATATION OF THE GLOTTIS IN LARYNGISMUS STRIDULUS.

Dilatation of the glottis, a valuable means to combat the spasm of the organ, should be employed in the symptomatic treatment

of the malady under consideration. The procedure consists in the introduction into the orifice of the glottis of a dilator with parallel branches; pressure should be made three or four times, and when the mucosities have been expelled the instrument should be removed. In a case reported by Constantin Paul (*Societe de Therapeutique,* February 10, 1892) the spasm ceased immediately. For a few moments the sibilant respiration and the access of oppression were noticed; but the child was able soon after to suckle.

SURGERY.

THE SURGICAL TREATMENT OF GRANULAR LIDS.

Darier, the chief of Abadie's Clinic in Paris, contributes an article in the *Archiv. d'Ophthalmologie*, February, 1892, concerning the treatment of granular lids, which has been found efficacious in this service. The following points are insisted upon:

(1) Anæsthesia with chloroform is indispensable in every case. (2) One of the most important conditions for the success of the operation is the complete eversion of the eyelids by means of special forceps, so that all points of the conjunctival cul-de-sac may be laid bare and submitted to grattage. (3) In order to attain this object it is very often necessary to enlarge the palpebral slit by incising the outer canthus and thus facilitating the exposure of every portion of the conjunctival cul-de-sac which is in the least affected with granular infiltration. (4) Scarifications are performed with the object of making the contents of the granulations apparent with the least destruction of the conjunctiva. (5) By means of a sharp scraper, and then of a brush composed of short, hard hairs, all morbid tissue is scraped and brushed as completely as possible. (6) An energetic and painstaking cleansing of the surface with a plug of cotton dipped in a sublimate solution, 1–500, ends the operation.

During the first day, iced compresses are applied and frequent lotions of sublimate solution, 1-2000. The patient should be examined daily, the eyelids everted, any sloughs detached, and the whole surface thoroughly cleansed with a sublimate solution, 1-500. At the end of fifteen days the conjunctiva presents a smooth, though somewhat tumefied, appearance, but granulations are invisible and there is no longer any secretion. In the event of the previous pannus, or other corneal complication, the improvement, dating from the first day of the operation, is stated to be surprising, and in the judgment of the reporter there is no treatment which has given such good results in so short a time. He attaches great importance to the regular use of a strong solution of sublimate, and recommends that the patients be watched for a month or two after the operation, and prompt interference be undertaken in case the smallest trace of the former disease should reappear.—*Ther. Gaz.*

HERNIÆ OF THE LARGE INTESTINE.

Gangolphe (*Lyon Mèd.*, January 17th, 1892) describes a case of hernia of the large intestine, from a consideration of which he makes the following generalizations: (1) Herniæ of the large intestine may be accompanied by an appendicitis in the hernial sack. (2) The localization of the inflammatory troubles to the hernia, the appearance of the fœtid suppuration without issue of gas or of solid matters, without serious functional troubles of the intestines, may perhaps in the future help in the diagnosis of this complication. (3) The radical cure, undertaken after a sufficient delay, is rendered particularly difficult, both by the adhesions which form and also by the difficulty experienced in recognizing the presence of the intestine. (4) As a general rule the necessary incision should be made along the antero-internal parts of herniæ, for in this way wounding the large intestine, should this be present, will be avoided.—*Brit. Med, Jour.*

OBSTETRICS.

DETERMINATION OF SEX.

The *Dublin Journal of the Medical Sciences* for March, quoting from *La Sperimentale*, says that "Dr. Serrano Montanel, of Valparaiso, read a paper before the last Chilian Medical Congress on the pro-

creation of either sex at will. After four years' observation, he had satisfied himself that we can pronounce upon the sex of an unborn fœtus if we know the number of menstruations which had occurred between the preceding delivery and the present pregnancy. If between the birth of one baby and the conception of the next an even number of menstruations have taken place, the second will be of the same sex as the first; if an uneven number, of different sex. This theory assumes the identity of menstruation and ovulation, which few accept, and also that ova discharged are of alternate sexes.

PHOCOMELOUS INFANT.

Martin Saint-Ange (*Jour. de l'Anat. et de la Physiol.*, No. 5, 1891) records a case of phocomelous monster with internal anomalies; the notes and description were found by Duvernet, and were published posthumously. The mother, aged 33, had previously given birth to two well-formed children. During her third pregnancy she had suffered from syncopal attacks and excessive irritability, alternating with melancholia. Fœtal movements were first felt at the sixth month, and were always very feeble. Labor occurred spontaneously at the ninth month, the breech presented, and delivery soon followed. There was some fibroid thickening of the placenta. The infant, which was living during labor, was born dead; it was of ordinary dimensions with the exception of the limbs, which resembled those of an embryo of a few months. There was symmetrical phocomely; each extremity terminated in six digits, which were very short and webbed; the bones of the carpus and tarsus formed an irregular mass; the two leg bones were united; the femora were nearly shapeless, and the humerus was normal in form but fused to the bones of the forearm. The heart was situated transversely, the foramen ovale was very large, as was also the ductus arteriosus, and there was a left superior vena cava, as well as the usual one on the right side. There was a large cleft of the palate, and the tongue, which was very small, was firmly fixed by a very short frænum. There were curious mammillated projections on the margins of the jaws. The right testicle was in the iliac fossa, the left in the scrotum. The penis was very small, and consisted of an imperforated glans and a divided prepuce. The urethral canal did not exist, but a duct passed from the inferior and posterior part of the bladder to the anal extremity of the rectum. This arrangement resembled that found in the monotrematous mammalia. A maternal impression was alleged as the cause, but, as it occurred late in pregnancy, this theory could not be entertained.—*Brit. Med. Jour.*

GYNECOLOGY.

RESECTION OF OVARIES AND TUBES.

A. Martin gives his (*Verhandl. d. Deutsch. Gesellsch. f. Gynäkologie*, 1891) experience of resection of ovaries and tubes, and expects that the operation will soon be recognized generally as a proper one. It is designed for the purpose of retaining for the woman her functional capacity. When, on removing one ovary or one set of adnexa, the other is found only partially involved in the disease, it need not be wholly removed. The diseased part of the ovary or tube is resected, and the remaining part is left, an artificial ostium abdominale being formed in the case of the tube. His results of resection of ovaries are—21 cases, 1 death from peritonitis. Of the 20 survivors, 5 have become pregnant, one operated on in May, 1888, having had 3 children. He has had 24 cases of resection of tubes,—1 death from general infection of the peritoneum by gonococci. Of the 23 survivors 1 became pregnant, but aborted in the third month.

ASCITES IN WOMEN, UNASSOCIATED WITH CARDIAC, HEPATIC, OR RENAL DISEASE.

Gusserow (*Centralbl. f. Gynäk.*, No. 19, 1892) opened an instructive discussion on this subject at a recent meeting of the Berlin Obstetrical Society. He for many years has always made an exploratory incision in these cases, being ready to take away any removable morbid growth that may be discovered. The conditions which give rise to this form of ascites are, according to Gusserow: (1) tuberculous peritonitis or "peritonitis nodosa" where no tubercle bacilli can be found; (2) pa-

pilloma of the surface of the ovary; (3) carcinoma and sarcoma of the ovary, usually with similar disease of the peritoneum; and lastly (4) rare cases where ascites exists in association with small non-malignant uterine and ovarian tumors or with tubal disease. In all these cases there is absence of œdema of the integuments and no signs of disease of the liver, heart, or kidneys. He rejects exploratory puncture, whether by means of a hypodermic syringe or the old trocar. Schäffer said that the ascitic fluid in cases of dropsy from inflammation or irritation of the peritoneum is of a specific gravity always exceeding 1015; whilst in cases of dropsy from stasis—including hepatic cirrhosis compressing large veins, and tumors or aneurisms pressing on the vena cava, diseases which may for long show no other symptom—the specific gravity of the fluid seldom exceeds 1012. Hence puncture is sometimes preferable to incision. The apparent cure of many cases of suspected "tuberculous peritonitis," when the ascitic fluid has been evacuated, suggests a non-tuberculous "peritonitis nodosa" imperfectly recognized by pathologists. Mackenrodt believes in this distinction, and declares that he has never known a case of cure after incision where true tubercle of the peritoneum was detected. He has frequently seen a diffused vesicular disease of the peritoneum associated with ascites—"herpes peritonei." This affection was not malignant and the ascites did not return after incision. Ascites is sometimes caused by enlarged non-malignant retroperitoneal glands; incision seems to cure these cases. Mackenrodt objects to puncture, as it may involve hæmorrhage or damage to internal organs; in incision these accidents are rare, and when they occur cannot be overlooked. Winter has not entirely rejected puncture; it allows of bimanual exploration of the pelvic organs. Incision is not without danger, and hastens death in cases of carcinoma. Gottschalk believes in a distinct peritonitis nodosa, but incision, he stated, sometimes cures true tuberculous peritonitis. Jaque related a case of severe hæmorrhage following puncture. In reply, Gusserow said that a low specific gravity of the fluid does not necessarily signify that the cause of disease is not removable by operation. Puncture does not allow of so perfect exploration as does incision.—*Brit. Med. Jour.*

PEDIATRICS.

TREATMENT OF CHOREA.

From a study of this important subject, Jumon (*La Medicine Moderne,* No. 9, 1892) has formulated the following conclusions: 1. In common choreas, the best results are obtained from the use of antipyrine and arsenic. 2. In the rheumatic choreas, or with rheumatic manifestations, antipyrine is still indicated, but to this drug may be associated the salicylate of sodium and sulphur baths which are certainly useful. 3. If there should be a large amount of hysteric element, the bromides, according to Dujardin-Beaumetz and Ollivier, are to be employed; 4. Finally in cardiac choreas, instead chloral and hydrotherapy both of which are dangerous, the iodide of potassium and especially that of calcium should be used, 5. In all cases physical exercise is to be recommended; especially at the gymnasium, this being often of great advantage.

TYPHOID FEVER IN CHILDREN.

A. Moussous (*Arch. Clin. de Bordeaux.* No. 4, 1892) states that in a series of fifty consecutive cases of typhoid fever in children under the age of 15 years he had only three deaths. He fully accepts the opinion that the disease is less serious in childhood than in adult life; there is less prostration, less hebetude, and seldom much diarrhœa or pneumonia. At the same time the fever presents the same characters as in the adult, and is often high—104° and even more; the pulse rate is often also increased to 140, but this rapidity has not the serious significance which it would have in the adult, nor are complications so often observed. The disease, however, is more severe in infants under 2 years than in children above that age; this fact is called in evidence to support the view that one of the reasons of the comparative mildness of the disease in children is the activity of their digestive secretions, which tend to inhibit the growth of the pathogenic organism. Another reason he finds in the greater functional activity of the liver and kidneys leading to a more perfect elimination of the poisonous bodies produced within the organism during the fever. On this head Moussous presents some new observations. Bouchard and others have

shown that the toxicity of the urine is increased by typhoid fever, and that this toxicity persists for a varying period after defervescence, for as much as four or five weeks when the disease is treated by the expectant method, for still longer if antipyrin is used. With the cold bath method the toxicity of the urine is very high during the fever, but ceases quickly when defervescence has taken place (Roque and Weill); naphthol diminishes the production of the poisonous substances both during the fever and during convalescence. Moussous finds the toxicity of the urine in children suffering from typhoid fever is sometimes increased during the pyrexial period, sometimes at its close, but that in either case it becomes normal after a few days of freedom from fever. The elimination of the poisonous substances, therefore, in children who are treated by the expectant method very nearly resembles their elimination in adults treated by baths. Moussous does not recommend resort to baths in the case of children, and notes one case in which serious syncope followed cold sponging. He advises the administration of laxatives every other day, a copious milk diet and small doses of quinine. —*Brit. Med. Jour.*

HYGIENE.

VACCINATION STATISTICS.

There still are found numerous opponents of protective vaccination and no amount of evidence seems sufficient to convince their biased minds. Yet the following statistics, capable of but one interpretation, may prove of interest: In Riga, a city of 180,000 inhabitants, there were some 6,500 belonging to a religious sect living by themselves in a certain quarter of the town. These people opposed the practice of vaccination on conscientious grounds. Between the years 1882 and 1887, the average mortality from small-pox in the city was 108 annually. From December, 1886, to the end of March, 1887, about four months, there were 155 deaths from this cause, owing to a slight epidemic during that period. Of this number 71 occurred among the orthodox population, equal to 109 per 10,000, while the deaths among the remaining inhabitants numbered only 84, equal to 4.8 per 10,000. Down to the year 1887, as stated above, the average number of deaths annually from small-pox was 108. After this epidemic vaccination and revaccination were largely enforced, with the result that from 108 the annual number of deaths due to this disease fell at once to 8.

NUTRITIVE VALUE OF MILK.

A child brought up on milk alone, and weighing at birth 3,200 grams, will gain in weight as follows:

During the	1st	three months	.....	23.35 gr. daily
"	2nd	"	.....	18.35 "
"	3rd	"	.....	13.5 "
"	4th	"	.....	8.00 "

Making the increase of weight during the first year about 6 kilograms.

During the 2nd year the increase in weight will be about 2 k. 000 gr.
During the 3rd year the increase in weight will be about 1 k. 200 gr.
During the 4th year the increase in weight will be about 1 k. 700 gr.

Making up to 5 years, a total increase of 12 k. 570 gr.—M. P. Cules, *in Rep. de Pharmacie.*

THE TRANSMISSIBILITY OF CARCINOMA

At a meeting of the Académie des Sciences, Duplay and Cazin (*La Mèdecine Modérne*, 1892, No. 8, p. 113) reported the results of investigations as to the inoculability of carcinoma. In a first series, comprising twenty-two observations, they inoculated, either subcutaneously into the peritoneum or into the blood, rabbits, guinea pigs, and dogs, with carcinomatous material obtained from man, in all instances with positive results. In a second series of experiments they inoculated animals with carcinomatous material obtained from dogs, but without producing more than a local inflammatory lesion, which underwent absorption. Attempts to transmit carcinoma from dog to dog also failed.

MEDICAL CHEMISTRY.

EGGIO.

This is a commercial article, presumably made from the yolks of eggs, the whites of which have been used for preparing egg albumin. An analysis recently made by C. S. Boyer, and reported to the Chemical Section of Franklin Institute, gives its composition by analysis as water, 53.75 to

56.91 per cent. ash, 9.47 to 19.25; fatty acids, 14.66 to 16.00. The yolk of egg examined by same method gives water, 51.8 to 53.72; ash, 1.0; fatty acids, 20.0. The conclusion is that the ash indicates the presence of sodium salts to prevent putrefaction, the presence of a little more water, and a little less of fatty acids than the egg yolk itself.

REAGENT FOR TANNIN.

Bæmes (*Monit. de la Pharm.*, 1891, 1006) uses as a reagent for tannin a solution containing in 10 cc., 1 gm. sodium tungstate and 2 gm. sodium acetate. This yields with tannin in acid or alkaline solution a straw-colored precipitate which is insoluble in water. The reaction is said to be very sensitive.

LITHIUM NITRIDE.

By heating lithium in a current of nitrogen gas, Ouvrard (*Comptes Rendus*, cxiv-120) has obtained a product containing 38 to 56 per cent of nitrogen, and his analysis leads him to conclude that the compound formed may be represented by the formula $Li_3 N$, or ammonia in which the hydrogen is replaced by three atoms of lithium.—*Pharm. Journ.*

ANTIPYRINE AND EUPHORINE.

When these two bodies are triturated it becomes difficult to obtain a powder that will admit of subdivision into papers. To overcome this, J. Mindls in the *Prag. Rdsch.* adds a little sugar and mixes with a spoon or spatula. A better powder may be obtained by rubbing the sugar first with a little bicarbonate of sodium before adding the medicaments. Powdered licorice root answers even better than sugar.

EXODYNE.

Exodyne (*Odyne*, pain) marketed by by the Orange Chemical Co. as the greatest analgesic and antirheumatic, consists, according to F. Goldmann (*Pharm. Zeit.*) of approximately 90 per cent. acetanilid, 5 per cent. sodium salicylate, and 5 per cent sodium bicarbonate.

NEWS AND MISCELLANY.

BOTTLING UP CHOLERA BACILLI.

A significant commentary on the question of interment in city cemeteries *v.* cremation is suggested by the incidents connected with a proposal in the Leeds Corporation Bill to drive a street through St. Mary's Churchyard, where a great number of cholera cases were interred, and Dr. Spottiswoode Cameron, in reporting against the proposed improvement, says: "The whole of the district is shale and clay. The corpses have, therefore, been bottled up for these sixty years in a practically impervious casing. I find there has been no epidemic in that neighborhood within memory of my present inspectors, and I find no record of any whatever. My own feeling about the matter is that I should be inclined to let well alone. Although the chances are strongly that, during the sixty years that are gone, the coma bacilli have died of inanition, there is a possibility that it may not be so, and that the opening of these graves might lead to disaster." The clause will be withdrawn and the clay-conserved bacilli left at rest.—*Brit. Med. Jour.*

TRICHINOSIS OF THE TONGUE.

A curious and interesting case, albeit somewhat difficult to understand, is recorded by Dr. Oitiz of Toire. The patient was a man, æt. 50, a robust countryman, with no history of syphilis nor of tuberculosis, who came for advice with an ulcerated growth of his tongue. The disease had been in progress about a year, and presented the characters of an epithelioma. Some misgivings, however, were expressed about the precise diagnosis, inasmuch as the ulceration was not of that foul nature such as usually occurs in connection with malignant disease. No improvement having followed the treatment adopted after a trial of a fortnight, it was decided to amputate the tongue. This was successfully performed, and on examination of the organ subsequently, the disease was found to be trichinosis, ulceration of the thickened tissue around the cysts having taking place.—*Med. Press.*

CH. MARCHAND'S

PEROXIDE OF HYDROGEN.

(MEDICINAL) H_2O_2 (ABSOLUTELY HARMLESS.)

THE MOST POWERFUL BACTERICIDE AND PUS DESTROYER.
ENDORSED BY THE MEDICAL PROFESSION.
UNIFORM IN STRENGTH, PURITY, STABILITY.
RETAINS GERMICIDAL POWER FOR ANY LENGTH OF TIME.
TAKEN INTERNALLY OR APPLIED EXTERNALLY WITH PERFECT SAFETY.

Send for free book of 72 pages giving articles by the following contributors:

DR. E. R. SQUIBB, of Brooklyn, N. Y. "On the Medicinal Uses of Hydrogen Peroxide." *Gaillard's Medical Journal*, N. Y.

DR. J. H. DeWOLF, of Baltimore, Md. "Medicinal Peroxide of Hydrogen and Glyco-zone." *Southern Medical and Surgical World* of Baltimore, Md.

NOTE.—Avoid substitutes—in shape of the commercial article bottled—unfit and unsafe to use as a medicine.

Ch. Marchand's Peroxide of Hydrogen (Medicinal) sold only in 4-oz., 8-oz., and 16-oz. bottles, bearing a blue label, white letters, red and gold border, with his signature. Never sold in bulk.

PHYSICIANS WILLING TO PAY EXPRESS CHARGES WILL RECEIVE FREE SAMPLE ON APPLICATION.

PREPARED ONLY BY

Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

SOLD BY LEADING DRUGGISTS.

Laboratory, 28 Prince Street, New York.

FRELIGH'S TABLETS,

(Cough and Constituent).

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{50}$ gr.), Atropiæ Sulph. ($\frac{1}{500}$ gr.), Codeia ($\frac{1}{10}$ gr.), Antimony Tart. ($\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{50}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonial from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of the profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that the applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

36 Maiden Lane, **New York City.**

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL & NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

ECLAMPSIA.

By DR. ROBERT OLSHAUSEN,
BERLIN, GERMANY.

PART III. (CONCLUSION.)

Continued from Page 46.

THE THEORY OF ECLAMPSIA.

We now come to a consideration of the theory of the disease. For a long time there have been two main views taken of this question. The one accepts the hypothesis of intoxication as a cause of the disease, while the other view looks for this in a change in the brain caused by anæmia and œdema.

The last named theory, which is usually designated as the Traube-Rosenstein theory has from the very first stood upon a very weak support, because it has been neither anatomically nor clinically proven, and also because the experimental support, which it received from an experiment on an animal by Oppler, was entirely valueless. This experiment was a single one, and so complicated, that just conclusions could not be gathered therefrom. The theory lacked in anatomical support for the reason that in the majority of all fatal cases any very great changes of the central nervous system are not recognized. Instead of the referred to anæmia of the brain, on the contrary a condition of hyperæmia is more frequently found, and also in only a part of the subjects, a slight œdema of the brain, or more frequently of the piamater is found. This œdema of the brain on which the coma is said to entirely depend, must be present in every case of eclampsia, according to the Traube-Rosenstein theory. Yet, I have seen as many as dozens of cases, in which even after long continued coma there was not the slightest vestige of œdema. Indeed, in the already mentioned case of eclampsia in which there were 104 attacks, the brain was so dry, that my colleague, who was performing the autopsy for me, said that one could speak of the presence of sclerosis with far greater justification than œdema.

The theory lacks clinical support, because it disregards the almost always present kidney symptoms. It only explain the rare exceptive cases in which there is no albuminuria. A theory which is expected to carry weight must above all things explain the rule rather than the exception. Further, the theory renders the presence of labor pains an almost absolute necessity for the existence of the disease; for the contracting uterus is supposed to compress the abdominal aorta, and to increase thus the pressure of blood in the upper half of the body and thus lead to cerebral œdema. The great frequency of premature births, (40 per cent.) however, which we have shown to occur in eclampsia, is a patent proof of the fact that the disease frequently begins during pregnancy. Also the frequent occurrence of the disease among primiparæ and in twin births, is unexplainable by means of this theory.

The poisoning or "intoxication" theory has, on the contrary, indisputable advantages over the former.

It accepts an intoxication by means of some excrementitial matter, which directly or indirectly is eliminated through the kidneys.

It therefore predisposes a hindrance to the renal secretion, or in other words, a renal disease, which in fact is almost always the case. What noxious substances, when retained, cause this intoxication, it cannot at present be said. That it is neither uric acid nor carbonate of ammonia

is certain. No one at present looks upon this disease as an uræmia in the true sense of the word. Whether we are dealing with a collection of kreatin, kreatinin, or urate of soda—as Stumpf suggests or with acentonæmia, or finally whether we are dealing with still other poisonous substances cannot as yet be determined. The clinical evidence in support of this view is so strong that its correctness is rendered most probable.

Before all, it must be determined as to what form of renal disease must be taken into consideration. Formerly in essaying to answer this question one's thoughts naturally reverted to chronic parenchymatous nephritis. As a fact, this disease can cause eclampsia, but only the fewest cases of eclampsia are due to such a chronic renal trouble. On the other hand, one can also say with correctness, that where chronic nephritis has existed before or during pregnancy, eclampsia only occurs exceptionally (in about ¼ of the cases). In such cases severe œdemas may often occur, such as anasarca, peritoneal or pleural dropsy, often interrupting pregnancy, and still more frequently a detachment causing the death of the fœtus. The mother also not infrequently succumbs at its subsequent birth, after a pregnancy of great suffering, but as has been said in such cases eclampsia occurs with relative rarity.

Especially through the investigations of Leyden and his pupils, we have come to learn that eclampsia is usually due to quite another and acute renal process, in which the principal feature is an acute fatty degeneration of the renal epithelium, in the tubulis contortis. The further results are the appearance of albumin in the urine, usually in an extraordinary amount, and a most severe and acute suppression of the secretion of urine, which is all the more severe since usually both kidneys are affected. If the process occurs gradually, as in chronic parenchymatous nephritis, and especially when one-sided, compensation is established by the action of the other kidney, or of the affected kidneys themselves. In acute disturbances, however, such a result is difficult, the poison is absorbed and the patient is intoxicated.

The rapid course of the eclampsia in favorable cases harmonizes well with the rapid course of the kidney affection in the same cases. No sooner has the eclampsia ceased than in the shortest time imaginable the renal troubles have also disappeared. In two days the amount of albumin will be reduced to a remarkable extent, no matter how large it may have been, and in four to eight days more all traces of it have disappeared. Simultaneously the previously greatly depressed diuresis becomes more free, and consciousness again returns.

The condition of the patient and the function of the kidneys, remind one forcibly of the *stadium asphycticum* of cholera, as in the latter, one may regard the appearances of free diuresis as a probable indication of ultimate recovery.

The proof of the fact that in Leyden's so called "kidney of pregnancy" we are dealing with an acute process, seems to me to be the most important point of the discovery. Now, all can readily understand the acute nature of the entire affection, both the eclamptic as well as the other symptoms.

The next question that comes to our mind is the manner of the development of the kidney symptoms, and their nature. Leyden is of the opinion that the condition is primarily one of acute anæmia, resulting in ischæmic necrosis of the renal epithelia. According to my own opinion the anatomical findings do not seem to accord with this view. On the contrary, apart from the fatty degeneration of the epithelia, the formation of cylinders in the passages of the inner substance of the organ especially, infiltration of the outer substance, and more frequently a hyperæmic condition, at least of the cortex, or outer substance of the kidney.

And now we come to a consideration of a more remote question, or the ætiological moment of the disease.

For a long time the changed pressure exerted upon the various organs in pregnancy has been blamed for these morbid processes, and as a fact good causes for such an opinion exist. The fact that seventy-five or eighty per cent. of eclamptics are primiparæ, and that among these, there are many with firm muscles, and therefore firm abdominal walls, and finally that twin-births and hydramnios are especially frequent in cases of eclampsia (among our 200 cases there were sixteen twin-births, instead of the nominal proportion of two to three)—all these facts seem to elucidate, and indeed to leave scarcely any room for doubt, but that the increased

intra-abdominal pressure plays an important part in the production of the disease.

The theory of Löhlein, Halbertsma, and others, to the effect that this pressure causes a compression of the ureters, and in this way checks the secretion of the kidneys, can assuredly not be set aside or disregarded.

Years ago, Stadtfeld called attention to the frequency of the dilatation of the ureters during pregnancy and parturition, and we have had opportunity enough to frequently verify this fact on the autopsy table. Stadtfeld* found in sixteen parturients, dilatation of the ureters nine times, either of one or both ureters.

In our records of the autopsies of 103 parturients, who died from diseases other than eclampsia, the condition of the kidneys is only referred to in seventy-five cases. In nine of these the ureters were not dilated, in twelve cases the ureter of one side was dilated (ten times the right side and twice the left); in four cases both ureters were dilated, but usually the right more than the left. The dilatation always began at the entrance of the small pelvis. That portion of the ureter lying in the lower or small pelvis was not dilated. Stadtfeld, who observed this, attributed it to a pressure on the ureter by the common iliac artery. In some instances this may be the case, in others it more probably is a pressure between the uterus and the bony ring of the pelvis. The predominence of the dilatation of the right ureter accords well with the frequency of dextro-version, and displacement of the uterus towards the right.†

That, however, the compression of the ureters and the renal disturbances resulting therefrom, constitute the usual, or even a frequent clause of eclampsia, is disproved by the post-mortem findings. Löhline in his thirty-two autopsies of eclamptic subjects found the ureters only dilated in eight cases. We found the right ureter dilated five times, the left once, with simultaneous intense hydronephrosis sinistra, in thirty-seven autopsies on eclamptics. Once we also found a slight hydronephrosis of the right side, but without dilatation of the corresponding ureter.

Here I agree with Schauta, in maintaining, that one most assuredly cannot blame the compression of the ureters with being a frequent cause of eclampsia. It is indeed most improbable that the compression of one ureter, even if continued and causing dilatation, would under ordinary circumstances cause such a disturbance of the renal secretions in general as to produce an uræmic intoxication. On the contrary, we do acknowledge that this may exceptionally be the case, and moreover consider that it was so in one of our cases.

In the case referred to the right kidney was a so-called "cystic-kidney," while the left ureter was considerably dilated, and the hydronephrosis was so intense, that in the report of the autopsy is read that- "the left kidney consisted only of a pyramid." This peculiar and rare complication must have occasioned a considerable disturbance of secretion, which might well have been productive of eclampsia without any other renal disease being present.

I hold that this case is vastly interesting and important, since it proves that a severe disturbance of the renal functions can result in eclampsia; independently of the way or means by which this disturbance, or rather obstruction, is brought about.

When, therefore, the compression of the ureters only plays an exceptional rôle in the production of eclampsia, and the intra-abdominal pressure seems to be a matter of importance, it can be asked whether or not a deleterious pressure is exerted upon the renal vessels. Leyden's views would lead one to think of a pressure upon the renal artery. I have already mentioned that the anatomical findings do not concur with this view, because of the frequent presence of a hyperæmia rather than an anæmia. An isolated pressure upon the artery, without affecting the vein, is scarcely to be thought of, since the two vessels lie so close to one another. A pressure upon the vein alone, or upon both vessels is more probable than upon the artery alone. That it is by no means an anatomical impossibility for the gravid uterus to exert a pressure upon the renal hilus, any one will acknowledge who has, either at autopsies or at laparotomies, noticed how the posterior walls of the soft uterus is flattened against the spinal column and other organs, in such manner

*Hospital's Tidende, June 26, 1861 ; see *Monatschr. f. Geb'k'de,* Vol. XX, p. 69.

†The fact that in 78 out of the 103 parturients, no notice was taken of the condition of the ureters, counts for naught, since many of these were admitted with peritonitis or pyæmia, often not until some time after the birth of the child.

as to seem spread out against the posterior abdominal wall.

The theory has been also advanced that the renal affections are only secondary, and occur after an infection or intoxication through some other channel. According to this view, the kidneys become affected and diseased, similarly as in scarlet fever, diphtheria and other diseases, in that the products of infection are eliminated through these organs, which cannot occur without occasioning a disturbance of the tissue and functions of the organs in question.

The attempts, which have been made by Doléris and others to demonstrate the infectious origin of eclampsia must be regarded as complete failures; and there is no probability of any explanation of the ætiology of the disease coming from this direction.

Then it has been endeavored to reconcile the theory of the products of tissue change (stoffwechsel) in the fœtus, which are absorbed into the maternal circulation, and thus causes eclampsia. This theory was supported by fact that in cases of eclampsia in which the course of pregnancy has not been interrupted; with the death of the fœtus the danger of a return of the eclampsia at its subsequent birth, is removed. This seems right enough, but it seems to me, besides the above, that in every case of eclampsia of pregnancy which has been checked without occasioning the birth of the fœtus, the disease will fail to return at the time of delivery, whether the child is dead or alive. I have seen two such cases (not included in the two hundred cases upon which this article is based), in which the pregnancy proceeded after the cessation of the eclampsia, and ended finally in the birth of a living child.

The one case was that of a duopara, twenty-eight years old, who had four eclamptic convulsions, and five days later, a fifth convulsion, and after the lapse of ten days more, was delivered of a living, although perhaps premature child, weighing 1760 grammes and 44 centimetres in length. The second case was that of a primipara who had thirteen convulsions. These ceased after the hypodermic exhibition of 0.05 gram. morphine, and the patient's consciousness fully returned. Twenty-four hours later labor began, and thirty-four hours after the last attack she delivered a living child.

C. Braun, also, in his work,* saw a living child born fourteen days after the cessation of eclampsia, and after the albuminuria had also disappeared.

In the yearly report of the Obstetrical Department of the Charité Hospital (Berlin) for 1888-89, there are four cases reported by Hensoldt, of eclampsia of pregnancy, in two of which living children were born three and seven days after the discontinuance of the eclamptic attacks, and without causing their removal.

Brummerstädt† has also reported that in thirteen cases of eclampsia occurring during pregnancy, between six hours and twenty-one days later, six dead and seven living children were born; and only in one case did the convulsions, which had ceased for six days, return.

Also the fact already referred to, that eclampsia not infrequently occurs long after the death of the fœtus, only tends further to prove the incorrectness of the theory in question.

So long as it has not been proven, that the death or life of the fœtus makes the least difference, the theory that eclampsia is due to an intoxication emanating from some fœtal secretion, has not the least weight.

I will now turn to a theory recently advanced by Herff‡ regarding the theory of eclampsia. According to this auther eclampsia is due to a peculiar excitability of the psychomotoric centres of the brain —for instance the subcortical centres. This excitability develops during pregnancy through the basis of an inherent psychopathic condition; yet that the physiological irritation produced by gestation does not usually suffice to cause the disease, but is augmented by other exciting causes, notably a slight *uratin* intoxication.

This explanation of the disease, so far as the psychological condition is concerned, seems to us to be an entirely unproven one, although it may seem justifiable to the views of modern neuro-pathologists who always look for some hereditary or neuropathological cause. Otherwise the theory, seems to contain only a round-about description of the facts of the case.

Among the means, which are at the

*C. Braun, *Lehrbuch d. gebh.* 1857, page 489.

†Loc. cit., p. 100.

‡*Münchener med. Wochenschrift*, 1891, No. 5.

service of investigators to enable them to clear away what is obscure regarding the disease, those made use of by Fehling and Stumpf, which deal with an examination of the secretions and blood, seem to us most justifiable. The experiments upon animals which have been undertaken in the endeavor to produce an artificial eclampsia have so far revealed nothing; and if they ever expect to, they must surely be undertaken in some different manner.

At this point, I would take the opportunity to say, that there is an intoxication, which is capable of producing convulsions, such as no experiments upon animals have equalled, and which resemble eclampsia convulsions to the most minute point. I refer to the intoxication, or poisoning producible by bichloride of mercury. The convulsions caused occasionally by this drug, are in every respect exactly like those of true eclampsia. They occur after short intervals, and may be easily mistaken for eclamptic convulsions.

This deception, as a fact, occurred in a case of ours. The patient was a septapara, in whom on account of a narrow pelvis, an abortion was contemplated, and with this end in view a bichloride solution (1 to 15,000) was injected between the fœtal membranes and the wall of the uterus. She was shortly after delivered of a dead child without assistance and eight days later had two eclamptic attacks. The temperature of the patient went up to 40. 30° C., and the pulse 116. The attack was considered to be eclamptic, and it was only the autopsy that revealed the truth. Besides the nephritis, there was diphtheritis of the large intestine, especially intense in the ascending colon. Both kidneys were enormously enlarged or, at a later examination (not undertaken by us) were found to be affected with necrosis of the epithelia, with a deposit of phosphate of lime in the passages of the organ.

The very late appearance of the eclampsia, at the eighth day of the puerperium, proves the correctness of this ætiology.

We can draw an instructive lesson from this case; namely, that in puerperal eclampsias which occur very late, the possibility of a bichloride of mercury poisoning (presupposing that the drug has been used) must be considered. In an exactly similar way, I observed eclamptic attacks in an old woman, which were not but a symptom of bichloride of mercury poisoning. One case, similar to ours, has been reported by Löhlein* The patient was a primipara, thirty-eight, who during the child-birth, had received several uterine injections of carbolic acid solution. Afterwards the acid appeared in the urine, and fifteen days after the birth of the child, the patient had five eclamptic attacks. The patient recovered.

It cannot be denied, however, that rarely cases of true puerperal eclampsia occur some time after delivery. In 1869 I saw such a case. The first attack occurred fifteen days post-partum, and the patient died after the fourth convulsion. The urine contained neither albumin nor cylinders. In the report of the autopsy, both kidneys were described as being in the "second stage of Bright's disease."† A few other cases have been reported by Löhlein.‡

Between this kind of toxic eclamptic convulsions and eclampsia gravidarum there is a decided analogy, which consists in a more or less acute obstruction of the secretion of urine, and it can also occur that both will have the same effect and cause the same pathological process. So, it can be very possible that in searching for the cause of the convulsions in bichloride of mercury poisoning, we may be able to throw additional light upon the cause of the true eclamptic convulsions. In order to tersely express my own theory as to the ætiology of *eclampsia gravidarum et parturientium,* I will briefly repeat what I have said at length in this article:

The disease consists in an intoxication, caused by what as a rule consists in a rather acute obstruction to the functions of the kidneys. The latter consists in the majority of cases in an acute or subacute pathological change in the parenchyma of the kidney, and especially also of the epithelium of the passages in the kidney. More rarely chronic parenchymatous nephritis (morbus Brightii), or interstitial nephritis can be the cause of the disturbed renal secretion; or, it may go as far as a chronic interstitial nephritis, and an acute fatty degeneration, in which case a deleterious result can be occasioned with greater ease. Exceptionally, entirely different changes in the kidneys can give rise to an acute suppression of the secretion of urine; for

**Zeitschr. f. Gebh.*, Vol. VIII., p. 537.

† See Maye, *Dissertation*, Halle, 1869.

‡ Löhlein, *loc. cit.*

instance, in especially favorable cases (such as previously impaired function of one kidney), acute suppression of the secretion of urine by compression of the ureter, and hydronephrosis or a pathological change of the renal parenchyma by toxic substances (bichloride of mercury or carbolic acid). These last add by far greater weight to the theory of intoxication.

If an attack of eclampsia ceased without interrupting the course of pregnancy, then at the birth which occurs later there is scarcely ever a repetition of the disease. That this is due to the death of the fœtus has not been proved.

For the prognosis of eclampsia the possibility of quickly terminating the delivery must be taken into consideration, as well as the number of convulsions and their intensity. A high temperature and a bad pulse indicate the worst possible prognosis.

The *sensu strictori* puerperal eclampsias seem to offer a favorable prognosis, if they occur within one or two hours after delivery. If they occur some time after delivery they offer a most unfavorable prognosis.

Numerous cases of eclampsia (30 to 40 per cent.) occur before any appearance of labor, during the course of pregnancy.

In a very few cases there is a warning or *aura* before the first eclamptic attack, or else it seems that the consciousness of the patient is retained during the first part of the convulsion.

The absence of albuminuria is a most rare occurrence, and also the absence of pathological changes of the kidneys (found at the autopsies) is very rare.

Regarding the therapy, I recommend morphine in large doses and when on account of the small pulse and greatly contracted pupils, no more may be given; then chloral by rectal injection.

In multiparæ the amniotic sac should be ruptured as soon as possible in order to induce, and accelerate the birth of the fœtus. So soon as the size of cervix no longer offers any opposition, the forceps should be resorted to. Version and incision of the cervix, is a practice that should be restricted as far as possible.

In exceptional cases, for the sake of the mother, or if she is moribund, for the sake of the child, Cæsarean section is indicated; but it is never quite impossible to give any precise indications as to when it is justifiable.

TRANSLATOR'S CONCLUSION.

In presenting this most exhaustive and admirable article on *Eclampsia* the translator feels convinced that the REPORTER, has made a valuable addition to the literature on this subject in the English language.

In translating, very little change from the original has been made, other than frequent amplification for the sake of clearness and a weeding out, as far as possible, of abstruse scientific terms, with which the original abounds, and then substitution of plain English. The writer's facile style has been reproduced as closely as possible. The quotations from other works have been verified as far as possible.

The following literature has been made use of in this work:

ON A GENERAL INFECTIOUS COMPLICATION IN LUPUS VULGARIS.

V. Lespinne (*Le Mercredi Mèdical*, 1891, No. 35) believes that there may be produced in the course of the evolution of lupus a special general complication due to absorption of toxic microbes taking place from the surface of the ulcer, this poisoning announcing itself by a sharp increase of temperature, with typhoidal state, catarrhal phenomena of the mucous membranes. This complication may be the signal for the period of invasion of the whole organism, general tuberculosis taking the place of the local tuberculosis of the skin.

HYSTERIA AND FÆCAL IMPACTION IN A NEUROTIC CHILD.

By PROF. CHAS. G. STOCKTON,
MEDICAL CLINIC, BUFFALO GENERAL HOSPITAL.

This little patient I have not seen before but I understand that the case is one of fæcal impaction. The history is as follows: H. S., aged 12, born in N. J., entered Hospital Sept. 29; parents, two brothers and two sisters living and well, none dead. The boy says that when a baby three weeks he was sick but his parents have never told him what the trouble was. From this time the abdomen began to increase in size. There is no history of traumatism. The patient can remember that the abdomen was considerably distended when he was four or five, and the bowels were very irregular, passage occurring at intervals of from three days to two weeks, and then unusually, because pills had been taken. After free movement of the bowels, the abdomen has diminished in size. No passage for three or four weeks till the day previous to entering hospital.

It is a good plan always to examine a patient carefully in a general way before beginning the special examination of the region supposed to be affected. The patient is a bright looking boy, though rather neurotic apparently. On raising his hand and arm, he holds the limb elevated for two or three minutes without moving. He lies unnaturally quiet for a child of his age, suggesting the state of trance. There is a peculiar tremor of the eye lids which is quite characteristic of hysteria. Children, even males, we must remember, are apt to be hysterical as well as women. The tongue is coated, rather broad and somewhat indented by the teeth. The gums appear fairly healthy and neither here or else-where is there evidence of anæmia. The breath is exceedingly unpleasant. The boy says his appetite is usually good though he ate no breakfast this morning.

The chest is cone-shaped as it usually is in young children who have punchy abdomens from accumulation of gas or fæcal matter, or from any enlargement of the viscera which causes encroachment on the thorax and stretching out of the lower ribs. If this child should maintain the stretching of his lower ribs until they have hardened from the deposition of lime salts, the chest would remain permanently in this shape. The crooked and variously distended chests which you so commonly see, date back in most cases to infancy and are due to abdominal distention or chronic cough, the result of bronchitis, emphysema, etc., particularly when rachitis is present.

Such an enormous abdomen might be due to distention of the stomach or intestine, to enlargement of the liver or spleen, or ascites. The liver is, of course, pressed upward, even if not enlarged, and we find on percussion that dullness begins just under the nipple. The area of dullness is not extensive, reaching barely to the edge of the ribs, but even there there is resonance due to the condition of the intestine. There is no indication of enlargement of the spleen, by percussion. The abdomen is tympanitic. So there cannot be ascites. The trouble is due to the distention of the intestines or stomach, or both.

Why should fæcal matter accumulate in the intestine of a child of this age? The causes of fæcal obstruction are usually to be studied in connection with the causes of chronic constipation. Chronic constipation in children must be due either to lack of innervation, and therefore loss of motility on the part of the muscular coat of the bowel, or to a lack of secretion, both of which elements facilitate the evacuation of the bowel. At the caecum there is a certain obstruction to the current of fæcal matter in the small intestine, and normally the consistency now increases gradually till it reaches the sigmoid flexure, which is a sort of valve, where the fæcal matter is held until the act of defecation. Sometimes, however, it is retained in the rectum, but normally above the sigmoid. Anything that will for a long time lead to imperfect secretion or imperfect motility of the bowels, will also cause constipation. The trouble more often occurs in the large intestine than in the small, and more often in the sigmoid region than in the rectum. Weakening of the motility of the intestine is a kind of paresis, and it may, in an extreme degree, almost amount to a paralysis. This lack of motility is apt to come about through negligence of the bowels; a person who does not respond to the demand of the bowels for evacuation, blunts the sensibility of the part and leads

to its sluggishness, and this is the most common way in which chronic constipation is acquired. Those who are disturbed in intellect and blunted in their sensibilities generally, are almost always affected with sluggishness of the bowels. The neurotic comes into this class and here we must place this boy. Again, the muscular coats of the intestine may be weakened from inflammation, the mucous membrane secreting less abundantly, and therefore furnishing less lubricating matter for the movement of the intestinal contents. Inflammation of the serous covering of the intestine—that is peritonitis—also causes weakening of the muscular power of the bowels. In chronic enteritis, the normal secretions are changed, mucus may be secreted in considerable quantities, but at other times, even that secretion is scanty. We therefore have diarrhœa followed by constipation, and again diarrhœa. With these cases of chronic catarrh we often find the accumulation of large scybalous masses which cannot be expelled, although around them the thinner fæcal matter passes and there are evacuations of the bowels while the hard masses remain in place. Sometimes these scybalæ become so hard that it is difficult to indent them except with a sharp instrument. This condition is rare in the small intestine, happening most frequently in the transverse colon and sigmoid flexure, but also in the caecum and the rectum. Persons thus affected may say that there is a regular movement of the bowels every two or three days, and on examination we may find the rectum filled with a hard mass, which no power of the the patient can expel, but the irritation may set up an increase of the secretion around it, and thus there will be periodical diarrhœa. This mass should be dug out with a spoon-handle, the spatula, or whatever happens to be at hand, and it may be softened with an emetic of warm water, assisted, it may be, by oxgall or Epsom salts.

In this case, on account of the neurotic element, the child has neglected to empty the bowels and a lack of motility has been developed. From the retained fæcal matter, gas is evolved which he belches up through the mouth. The foul breath and the coated tongue are very natural accompaniments. One would suppose that there would be sufficient toxæmia from the long retention of fæcal matter to make the boy sick but his general condition seems good and he has no fever. I should advise giving him in the first place calomel to stimulate the secretion of the bowel, with it might be given small quantities of ipecac. I should then give him castor-oil in regular doses, perhaps half an ounce every two hours repeated till the bowels are empty. Meanwhile the bowels should be cleaned out from below, by the finger and spoon if necessary, in order to empty the rectum, and following this an enema and then a soft tube should be introduced 24 to 30 inches and a solution of ox-gall ℥ij. to a quart of water should be carried high into the colon. This is usually the most efficient means of softening such a hard fæcal mass.

Note.—Ten days later the boy was presented at the clinic, when he was apparently well. This change resulted from the treatment described to you, with the addition of half a pint of the milk of asafœtida, in divided doses daily.

Further observation showed that the boy was in the highest degree hysterical and, undoubtedly, for his improvement we are largely indebted to the asafœtida.

A NEW VARIETY OF TROPHO-NEUROSIS OF THE SKIN.

Mm. Hollopeau and Larat (*La Semaine Médicale*, 1891, No. 47) describes a condition of the skin characterized by dyschromia and lichenoid eruption. Reference is made to the various dyschromias due to nervous origin which have been described by authors, and to the concomitant phenomena, consisting of disturbances of sensibility and of the vascular system, and disorders of secretion; to which may be added, as shown by a case of the author's, impaired nutrition of the hairs. A case recently observed shows that lichenoid papules may also be produced by the same causes. They make a résumé of their observations as follows: There exists a dermatosis characterized by achromatous patches surrounded by a papular border and by increased pigmentation. This dermatosis is probably a cutaneous manifestation or hysteria. The papules, lichenoid in kind, may be of a tropho-neurotic origin. They are not necessarily akin to pruritus. Cutaneous electrization in the form of bath, with the faradic current, seems to be indicated.

Communications.

DISCUSSION ON ELECTRICAL EXECUTION.*

By A. D. ROCKWELL, M. D.
NEW YORK.

While I do not believe that the best use to which a man can be put is to kill him, yet all will agree that if the law will kill, let it kill decently. It is evident that the sentiment against hanging and in favor of some method quicker and less repulsive is strengthening and that other methods will sooner or later replace the rope everywhere. Mr. Edison while in Paris during the exposition gave his opinion so positively in regard to the efficiency of electricity that the Medical section of the French Academy of Sciences aided by Marcel Duprez, a prominent electrician, have had the matter under careful investigation. There is always opposition and friction attending changes for the better, and this change has been no exception to the general rule. The whole tendency of our civilization is however in the direction of humane methods in dealing with criminals and that form of execution which is quickest and least repulsive should be adopted. It is a mathematical impossibility that any human being receiving in proper form an electrical current of lethal energy should appreciate even for a fraction of a second the slightest pain. It has been ascertained that the brain is one-twenty-fifth of a second in recognizing an impression, and one-twenty-eighth of a second in telegraphing that an impression has been received, and as nerve force travels only about 100 feet a second, while the velocity of the electric current is millions of times greater than this, the brain has absolutely no time to appreciate a sense of pain. As between electricity and certain other methods of capital punishment it is not altogether clear that the former is the best that could be suggested. The guillotine and the garote are practically instantaneous and painless in their action and attended with only a fraction of the paraphernalia and expense of the method now adopted in New York State. There is however an apparent brutality attending both these methods that repels, and a mutilation and shedding of blood, which public opinion in this country seems unwilling to tolerate.

The action of poison is open to none of these objections, and it seems somewhat singular that it has not more strongly commended itself to the philanthropic mind seeking simpler and more humane methods in the legal taking of human life. But as between electricity and the rope there can, it seems to me, be no question. Let us suppose that it had been customary to execute by electricity instead of by hanging, and that some one in the supposed interests of humanity should suggest that the former method be abolished, and the latter substituted; that a method practically instantaneous and painless, unattended by mutilation and without any distressing outward manifestations of pain, be replaced by one which usually fails to extinguish life for ten or twelve minutes, which in many cases it is reasonable to believe is attended with torture, and where the convulsive manifestations are horrible to witness—such a suggestion could not have the slightest claim for serious consideration, and as a matter of fact would never be offered.

After the passage by the legislature of the state of New York of the law substituting electricity for hanging in the execution of criminals, there arose a terrible storm of opposition that apparently had for its basis extensive commercial interests. It was claimed by the opponents of the new method, that electricity was by no means certain to destroy life without the infliction of great pain, and the popular mind was agitated by repeated assertions of the possibility and probability of repulsive disfigurement by the heat and chemical action that would necessarily be developed in the use of currents of such great power. To determine these points and to advise the state as to the best methods of procedure, a commission was appointed consisting of Dr. Carlos MacDonald, Chairman of the State Commission in Lunacy, Prof. L. H. Lady, of Columbia College, and the writer, who both at the Edison Laboratory and at the various prisons of the state, experimented largely upon animals, and tested many devices and methods for the application of the current. There could be no charge of cruelty in these investigations

* Read before the Neurological Section of the American Medical Association, Detroit, June 8, 1892.

for in no single instance was there any evidence that the slightest pain was inflicted.

The largest animals such as horses and a bull instantly succumbed to an electric pressure of one thousand volts, while dogs and calves were as readily destroyed by five and six hundred volts.

But one impact of the current was found necessary, for death was instantaneous in every case.

Immediate examination after the opening of the circuit invariably failed to elicit the slightest respiration or heart beat, and careful and persistent efforts at artificial respiration conducted by Dr. Fell, of Buffalo, with the latest and most approved appliances were without avail.

In view of the fact thus satisfactorily demonstrated that one thousand or at the most fifteen hundred volts would instantly kill any animal large or small, we very naturally inferred that any human being would succumb even more readily, but to make assurance doubly sure, it was recommended that not less than 1,500 or 2,000 volts be employed in the execution of criminals. To our great surprise therefore it was demonstrated at the first electrical execution and confirmed in every subsequent attempt, that it was far more difficult to kill a man by electricity than any ordinary domestic animal however large. In the only execution which the writer attended, when four criminals were successively subjected to the electric stroke, the first contact of twenty seconds with a voltage of 1,700 left its victim apparently lifeless, with the exception of a slight fluttering of the pulse and what appeared to be a slight expiratory effort.

Because of these faint evidences of vitality it was decided then and has been customary since to repeat the shock once and sometimes twice. That the victims were however in every instance so thoroughly devitalized by the first shock as to preclude the possibility of resuscitation, and that every vestige of consciousness was instantly obliterated, admitted of not a shadow of a doubt. In these cases a man's brain acts in two ways and I should say that the reasons for this increased strength of current necessary in the case of a human being were both physical and psychical. In the first place, the man knows what is coming and every nerve and muscle is tense with involuntary resistance. There is a mysterious likeness between nervous force and electric force; not a resemblance exactly, but a something about each which science has yet to fathom.

I have no doubt that this nervous tension operates directly to impede the action of the electricity, while the secondary effect is physical. The body conducts electricity by virtue of its saline solutions.

Now, fright drives the blood away from the surface to the central portions of the body.

When a man is placed in the chair he is necessarily terribly frightened, and the result is that the surface tissues are unnaturally dry, and hence inferior conductors. With an animal these influences do not prevail, but the most striking confirmation of the probable truth of this suggestion lies in the fact of the greater readiness with which life is extinguished in men from accidental contact with electrical energy.

Even where the contact has been incomplete and imperfect, linemen have been instantly killed with electrical potentials no greater than those employed in judicial executions. When a man thus accidentally comes in contact with the current, his will or nervous force is in a passive state and offers no resistance to the action of the current, while the surface of the body is usually flushed with the exertion of work and in the highest state of conductivity. Notwithstanding the efforts of a united press to exaggerate results, no one who has once witnessed a properly conducted execution by electricity can fail to commend it as a most humane method as compared to hanging. Aside from the fact that a human life is being taken by violence, there is little in connection with the execution that is revolting to the senses. After the first convulsive movement as the current is received, every muscle is simply tense and motionless until the current is broken when relaxation takes place and the man is to all intents dead.

It will be recollected that the press raised a great outcry against the use of electricity, not only because of its supposed inefficiency, but because of what was described as repulsive mutilation by burns and scalds. While the degree of heat generated and the influence exerted upon the superficial tissues, varied in the different cases, according to the position

of the electrodes and the density of the current near the points of contact, in no instance was there any such repulsive disfigurement as has been intimated, and in all but one or two the effects produced were so superficial and slight as to be unworthy of comment. It cannot be denied however, that owing to the limited area through which the tremendous voltage required has to operate, and the immense resistance offered to its passage there occurs a remarkable drop in potential and an astonishing development of heat, which, without the exercise of the most intelligent and careful supervision, might result in such severe burning as to bring under public condemnation a method which thus far commended itself to all eye-witnesses.

But it is not voltage alone that kills, but its rate of expenditure in the body as expressed by amperes, and the time consumed in its expenditure as expressed by the volt, ampere seconds indicating the measure of the heat developed during the action of the current. As stated by the distinguished electrical expert, W. J. Jenks: "None of these factors are well settled as yet in their relation to the energy actually required to cause instant and painless death. By death, I mean now not alone cessation of consciousness of a perfectly healthy human being in an interval too brief for thought to measure and the establishment of conditions which produce gradual and final expenditure of the stored nervous energy of the brain and the subordinate centres of distribution of vital force—such as the pneumogastric nerve and the spinal cord—I mean also, total paralysis of all the vital organs and of the nervous centres by which they are directly or indirectly vitalized, and by which the muscles of the extremities are actuated, so that when the current is broken there can be no reflex action of the muscles, such as would indicate the presence of residual life energy, or a possibility of its resuscitation."

The question which physicists must determine is how with a comparatively low voltage the same number of amperes that are expended upon the periphery and therefore in a measure lost—could be made to act exclusively on the centres of life and nervous activity, instantly devitalizing them while leaving no outward manifestations of the terrific power employed. It has been asserted that the subject of executions by electricity is one with which the physician should have nothing to do, and vigorous protests have been made against the propriety of allowing the subject of legal executions to be discussed in our medical societies.

In arguing that the function of the physician is to save life and not to be in any way connected with devices that destroy, it is forgotten that in one of the departments of our art, our noblest efforts are enlisted in taking, for the purpose of saving life; and when death is inevitable the physician is at hand to soften the transition from visible time to invisible eternity. When the law therefore decides that some new and better method be adopted in the disposition of those against whom its heaviest penalty has been decreed, who but he should be selected to advise the state as to the proper technical methods of procedure.

Whatever is worthy in action, is proper in discussion and as one of the advisory commission appointed by my state in the interests of the best methods of execution by electricity, I have felt that our work was never along more truly professional lines or more in the interests of humanity.

THE TREATMENT OF HÆMORRHOIDS.

At a meeting of the Medical Society of London, Lauder Brunton (*Lancet*, No. 3576, p. 583) dwelt upon the influence of cold and over-eating in the development of hæmorrhoids. Mercurials, followed by mild salines, are useful in preventing hepatic congestion. Aloes, in large doses, may conduce to the development of hæmorrhoids by over-stimulation of the muscular coats of the rectum. Small doses, on the contrary, exert a beneficial influence. Hepatic congestion due to cold may be relieved by the application of hot-water bags to the nape of the neck and over the liver. Patients subject to hæmorrhoids should become accustomed to emptying the bowels at night, so as to secure rest in the recumbent posture. When there is much irritability at the anus it is preferable to use a soft sponge and water instead of paper more or less harsh. A pledget of animal wool dipped in hamamelis and introduced into the rectum will act as a mechanical support and as an astringent. In obstinate cases an anal pad may afford great relief.

ACUTE RHINITIS WITH RETENTION OF SECRETION.*

By C. E. PERKINS, M. D.,

SANDUSKY, OHIO.

In taking up a small portion of your time, to-day, I desire to call your attention to a case which has been very interesting as well as somewhat perplexing to me, and I hope that the narration of this case may bring to your minds similar ones which you have met in your experience. And if it does, I would like to ask you to narrate them for our mutual profit, as in trying to find some elucidation of this subject, in text books and articles in medical journals, I have been greatly disappointed. We know that but very few cases, comparatively speaking, of acute catarrhal rhinitis are accompanied with symptoms of sufficiently severe character to lead the patient to consult a physician, but that these do occur in which the diagnosis is very difficult and the symptoms severe, I think will be shown from the following case:

Miss M. K., aged 30, unmarried, consulted me on Feb. 9th, this year; her family, as well as personal history, was negative as to tubercular, rheumatic and specific disease; unless we might be inclined to consider an attack of measles (so called) occurring in January, '91 as a syphilitic manifestation; but I cannot do so as some four or five other members of the family had the same trouble at the same time and all recovered without treatment of any kind. Up to the commencement of this trouble she had been exceptionally healthy and robust, having never required the services of a physician.

In the latter part of October last she was taken with what she considered an ordinary cold. There were the ordinary symptoms of acute catarrhal rhinitis, viz: malaise, dryness and heat of the nose followed by discharge, etc., etc., but she had in addition to all these a severe neuralgia on the right side of the face, which persisted for about a month. Early in December complete stenosis of the right side of the nose developed and the left was partially occluded. At this time there was a swelling across the nose, frontal and nasal pains, and slight epiphora, and there was very little running from the nose and that of a watery character. About these same symptoms continued until just before Christmas when she consulted her physician. I am quite certain that he considered the case as one of nasal syphilis, for he prescribed mercurial inunctions and insufflated iodoform daily. She continued under his care for six weeks. At one time in January she had a hoarseness for one week. The right nostril continued occluded and the left became completely so, although he was adopting rigorous antisyphilitic treatment. Not making any improvement she consulted me on the 9th of February. I found her weak and anæmic and somewhat emaciated. There was complete loss of appetite, and swelling, redness, and pains across the nose.

These pains were so severe as to interfere with sleep; there was complete stenosis of both nasal passages which caused the characteristic voice of nasal occlusion. This, upon inspection, appeared to be due to thickening and infiltration of the turbinated bodies and septum; they were in contact about one fourth of an inch from the anterior nares. Having benumbed the parts with cocaine, I introduced a probe, wound with cotton, beyond this point of contact and brought out some cheesy matter of disagreeable odor. I was unable to get a thorough view of the nasal cavities at that time so I directed her to return on the following day; then I found the œdamatous swelling somewhat subsided and saw that there was a polypoid enlargement of the middle turbinated bodies which acted as a valve to imprison the decomposing material.

This I removed with cold wire snare. And thus opened up a regular cavity on each side, from which I removed at least an ounce of foul-smelling cheesy pus. I might add that this accumulation was above the middle turbinateds so far as I could make out. As the parts were thus opened, and the discharge was enabled to make an exit, it gave rise, by running down into the throat, to a very distressing nausea. This I succeeded in relieving by daily removing these secretions and spraying the nares with a solution of peroxide of hydrogen, "Marchand," one to four of water, and a mixture, taken internally, of pepsin and bismuth; I also prescribed champagne. Under this treatment the

*Read before Ohio State Medical Society at Cincinnati, May 6th, 1892.

patient soon began to improve. She regained her appetite, the stenosis was relieved, fœtor stopped, and she began to gain in flesh and strength, and on the 4th of March I permitted her to go home, some ten miles, to report occasionally; she continued to improve until the 24th of March, when she returned complaining of obstruction in the right nasal cavity. Then I removed the last bit of decomposed mucous, which had become very much hardened; since which time she has remained well. I examined her on the 26th of April and found the nasal cavities as nearly normal as we are accustomed to see them: there was no ulceration, nor was there any perforation of the septum, or anything to suggest to one that a syphilitic process had been going on.

This case has been a very perplexing one to me as far as the diagnosis is concerned. I cannot regard it as syphilitic, as the effect of antisyphilitic remedies was of no avail, but positively hurtful, and the case got well without any of the results, such as perforation of the septum, exfoliation of bone, etc., which we should expect to result from such a severe syphilitic manifestation.

I am perfectly convinced that it was a case where the patient was taken with acute catarrhal rhinitis and as a result of the swelling of the mucous membrane, the discharge was retained and becoming decomposed gave rise to the train of symptoms occurring in the case. There might have been implication of some of the accessory sinuses, but I think that there was not to any extent at least. In looking over the literature of this subject as far as I have had an opportunity, it is surprising how little is to be found. The only contribution is from the pen of Middlemass Hunt, of Liverpool, which occurs in the journal of *Laryngology, Rhinology and Otology,* page 1, vol. 6, there under the head of "Serious Symptoms Arising from Retention of Nasal Discharge," he relates two cases. The first was a girl aged 23, who had had the trouble for a year with complete stenosis of the right nostril. Before coming under his care the case had been diagnosed as one of malignant disease. He destroyed the folds of mucous membrane which held the secretion in the nose, and "scooped out the putty like material." The case resulted in a cure. The second case was a widow aged 45. She had about the same symptoms except that the neuralgic pains were more severe. Her medical attendant had diagnosed syphilis and had salivated her without effect. The same foul smelling cheesy material was found in the nasal cavity of the right side. He adopted the same treatment except that he snared the hypertrophied turbinated valve, as it were. In his cases, owing to the length of time the disease had persisted, the fold which had obstructed the exit of the discharge had become almost the same as granulation tissue, while in mine, from the short length of time, about five months, it was mucous membrane infiltrated with serum greatly resembling true myxoma. His also differs in being unilateral, whereas, mine was on both sides. His conclusion is this, and I quote in his own words: "The sequence of events, in the above cases seem to be as follows: An acute nasal catarrh, extending to one of the accessory cavities, most probably the frontal sinus, with swelling and inflammatory hypertrophy of the mucous membrane. Leading to gradual occlusion of the nostril and retention of the discharge, which gradually filled the nasal cavity, became inspisated, and, through pressure gave rise to pain and deformity. Disease of the antrum is excluded by the cessation of all symptoms after removal of obstruction."

I wish to say that my patient was well before I saw Dr. Hunt's article, but if I had seen it sooner it would have been a great help to me as well as a relief. And now in conclusion, I wish to add that I reported this case more because I have considered it my duty than for any other reason, and I hope it will impress upon your minds that cases do occur where there may be a foul-smelling cheesy accumulation in nasal cavities without syphilis or ulceration of the mucous membrane, notwithstanding what some of our best authorities on nose and throat disease may hold in their writings.

VENTRAL HERNIA RESULTING FROM ABDOMINAL SECTION.*

By D. TOD GILLIAM, M. D.,
COLUMBUS, OHIO.

The safeguards against ventral hernia are the slippery and vaulted parietal peritoneum which continually shifts the pressure, the fascia, the interwoven commissural fibres, the arrangement of the fibres of three sets of muscles. The factors contributing to ventral hernia are a roughened and sacculated peritoneum concentrating the pressure, scar tissue which has not the power of resistance of normal tissue, and the disturbance of relations of the parietal components.

In long standing cases with large and pendulous pouch, the viscera become displaced, the mesentery prolapsed, and the cavity properly contracted. This adds greatly to the difficulties of the operation, because the cavity can no longer accommodate the viscera.

The ideal operation would be to restore a smooth, regular peritoneum, and the normal relations of the superimposed structures to enlarge the cavity and to strengthen the visceral supports. This as a rule is impracticable, and the intra-peritoneal operation is fraught with so much danger as to condemn it.

The operation of cutting down to the fascia on one side the median line, reflecting it to an equal distance on the opposite side, dissecting up the muscles from the middle line outward in both directions, overlaping and securing them by suture, is full of difficulties, and while offering many advantages over the direct median section, is not likely to come into general use.

The operation of election must be simple, safe, easy of execution and lasting in its results. A preliminary treatment is necessary to enlarge the cavity, restore the viscera and strengthen the muscles. This will consist in keeping the patient recumbent, regulating the bowels, massage, the Trendelenberg posture, and the use of remedies to combat flatulence. The utmost care is necessary to secure asepis, for the efficacy of the operation depends upon the avoidance of suppuration. The operation will consist in an elliptical denudation of an inch or more in width, around the margin of the hernial pouch, and to the depth of the fascia, infolding of the hernial pouch towards the cavity, and seried layers of buried catgut sutures so as to coapt the denuded surfaces perfectly. The dressings consist of antiseptic gauze held in place by strips of adhesive plaster anchored well down on the sides and tied with tapes over the median line. Over all, the cotton pad and flannel bandage.

*Abstract of paper read before Ohio State Medical Society, May 6, 1892.

ECLAMPSIA AND SEPTICÆMIA.

Loviot (*Nouv. Arch. d' Obstét. et de Gynéc.*, November, 1891, Supplement, p. 482) describes a highly-complex labor where the patient was saved after extreme complications. She was a primipara, aged twenty-seven. Loviot found her in labor at term, and very badly nursed. The first twin presented at the breech; the forceps were applied and it was delivered. Then the patient was allowed to rest for an hour, the pains being very feeble in the meantime. The head presented, the membranes were ruptured, the forceps applied, and the child safely delivered. The twins were males and both alive; there were two placentæ. The patient's previous medical attendant had detected a great quantity of albumin in the urine. Antiseptic solutions were injected. Three hours later the patient had a fit. She was not treated with care; delirium set in and when Loviot was called in, two days and a-half after he had delivered the child, he found her temperature 105°, liquid motion pouring away from the bowel, and fœtid lochia discharging from the uterus. A large slough involved the vulva and a tract of the vagina. The slough was scraped away, several litres of solution of sublimate (twenty-five centigrammes to a litre of water) injected into the uterus, and the raw surfaces powdered with iodoform. The vagina was drained with iodoform gauze. The next day the curette was applied to the uterus, which was drained with the same dressing. At the end of the third week there was slight phlebitis in the right leg, which lasted six days. The patient shortly afterwards left for the country, her health being perfectly re-established, excepting that the urine contained a trace of albumin.—*Brit. Med. Jour.*

INFANTILE PARALYSIS.*

By D. R. BROWER, M. D.,
CHICAGO, ILL.

Polio-Myelitis Anterior Acuta, Essential Paralysis of Infancy or Acute Trophic Paralysis of Childhood is an affection of the spinal cord characterized by a sudden febrile onset, often-times with general convulsions and a paralysis of variable distribution, with a rapid atrophy of the paralyzed muscles, and an absence of sensory disturbance and of disorder of the functions of the rectum and bladder.

Its causation is involved in mystery; while it does sometimes occur in adults, yet it is essentially a disease of infancy, cases occurring most frequently between the ages of six months and four years. There does not seem to be any well marked heredity, but it has an ætiological relation to the seasons of the year, occurring most frequently in the summer months. Dr. Sinkler, of Philadelphia, in an examination of a great many cases, determined that four-fifths of the cases occurred during the hot months.

Traumatic influences have been supposed by some to have an important causal relation. The acute febrile affections not infrequently have preceded the development of this disease.

There is no proof that the disease bears any relation to the processes of dentition. The rapid functional development of the nervous system between the periods of life in which it has its greatest frequency, having probably more to do with its development at this time than any physiological process of the body.

Symptoms.—The clinical history of the affection divides itself into four periods: *First*, the period of invasion, which lasts from a few hours to a week; *second*, a stationary period, which lasts for a week or a month; *third*, a stage of regression of paralytic phenomena, lasting from one to six months, and, *fourth*, a chronic stage of an indefinite duration. The period of invasion begins usually with febrile excitement, the temperature reaching 103° or 104 deg., and sometimes 105 deg. Convulsions occasionally attend the onset, especially in young children; there is more or less pain in the back; vomiting and diarrhœa are not infrequent accompaniments; indeed, this onset presents constitutional disturbances very much like the ordinary febriculæ of childhood, and I know of no means by which its differentiation can certainly be established. I think if we are called to see a patient in this stage of the disease we will very rarely, if ever, apprehend the cause of the constitutional symptoms, but in a day or two the child will be found to be paralyzed in some muscles, or groups of muscles. This paralysis is always rapidly developed; only a part of a limb may be affected, or both arms, both legs, or a leg and one arm may be paralyzed.

The amount of paralysis found to be present in this, the second stage of the disease, always reaches its maximum almost immediately—it possesses no progressive character. The sensibility is almost entirely undisturbed throughout the whole progress of the disease; at the very onset they may complain of pains, but these painful symptoms are of short duration. Reflex function, superficial and deep, is abolished in all the muscles that are paralyzed. The functions of the bladder and rectum usually escape involvement, except during the first few day there may be trouble with both these organs, but whatever disturbance there is in these functions after a few days disappear.

After a certain time the period of regression begins during which the paralysis disappears, except from certain parts in which atrophy occurs. There are certain cases in which recovery may be complete and it has been proposed to call these cases temporary spinal paralysis, but as a rule a certain number of muscles undergo very rapid recovery.

The temperature of the paralyzed limbs is lower than the corresponding sound one, the difference usually being several degrees. The sensibility of the skin of the paralyzed limbs is not impaired. These atrophied muscles will not respond as a rule, to Faradic electricity, but usually do respond to interrupted galvanic currents of sufficient degree of intensity. During this period of atrophy there is arrest of development in the osseous system so that the limb gradually becomes shorter than its fellow, and the difference in size increases with the amount of general growth, hence this difference is greater

*Read before the Illinois State Medical Society, May, 18, 1892.

the younger the patient at the onset of the disease. There is also during this stage, a great tendency to the occurrence of permanent shortening of the muscles and consequent displacement of the parts to which they are attached, deformities are thus produced. Certain muscles of the lower extremities suffer more frequently than others with permanent paralysis, and of these, the antero-external group of the leg, the long extensor of the toes, the tibialis anticus, the superficial extensor of the great toe, and the long and short perinei are those most commonly affected. When the upper extremity is the seat of paralysis, the extensor muscles of the hand are those most frequently paralyzed. Bed-sores, or atrophic ulcerations of the skin are exceedingly rare. Relapses are very rare, and second attacks are almost unknown; but a single instance of this kind has come under my observation. Occasionally, however, the disease occurring in childhood seems to lay the foundation for the development of other spinal affections later in life; lateral sclerosis, posterior spinal sclerosis and progressive muscular atrophy occasionally follow in the adult period.

Pathology.—This disease is due to an inflammation that has its beginning either in the interstitial tissue, or in the parenchymatous tissue of the anterior horns of the spinal cord, and either as a consequence of the essential parenchymatous inflammation, or as a consequence of this interstital inflammation there is destruction of the cells of the anterior horns of the spinal cord, and these cells being motor and trophic in function, their destruction results in wasting and paralysis. In some very severe cases there is a slight local meningitis. The original disturbance of function being very much greater than the amount of degeneration that has been produced, results in the clinical fact that the paralysis immediately following the onset is very much greater than that which is to be present after a few days. The probability is, that this inflammatory disturbance has its origin in the presence in the blood of some pathological germs.

Diagnosis.—As already stated, it is almost impossible to make a diagnosis in childhood of the invasion period; the differentiation of the paralysis depends upon the fact that the atrophy is rapid, that the temperature of the limb is below normal, that there are no sensory disturbances, and the bladder and rectum perform their functions normally.

Prognosis.—Occasionally children die in the acute onset, doubtless without the precise cause of death being determined; beyond this there is no danger to life. The prognosis as to recovery is to be based upon the condition of the paralyzed muscles; if the muscles have not lost their electrical irritability, then there is hope of recovery to a greater or less extent, but otherwise, the prognosis as to recovery is absolutely unfavorable.

Treatment.—The treatment of the acute stage of the disease consists in the administration of antipyretics: Antipyrin, bromide of sodium, salicylate of sodium and ergot, if the disease can be recognized in this stage. When the acute stage is over, then the tonics are indicated, iron, quinine and strychnia in the beginning, cautiously. In some cases cod-liver oil and the syrup of hypophosphites are extremely useful. The most important agent in the treatment of this affection is electricity, and the constant galvanic current should be used as soon as the fever has subsided, and should be made to pass through the seat of the lesion in the cord. The electrodes used should be large, and the current should be mild and its duration should be five to ten minutes. At a later period of the disease, when atrophy of the muscles has set in, the interrupted galvanic current should be used to the paralyzed muscles, of the least strength that will produce muscular response, and each paralyzed muscle or each group of muscles should be made to respond to this electrical stimulus not more than once or twice at each seance. As the muscles improve in tonus, less strength of current will be necessary, and after a time the muscles respond to the Faradic stimulation.

The electricity should be applied by the physician in person, much of the want of success in the treatment of this disease being due to the non-observance of this rule. It is a common experience for me to be consulted by the friends of these patients and when I advise the use of electricity to be told that they have been using it, and it has been of no value; and upon further investigation find that they have themselves been applying the current from a Faradic battery, that was incapable of producing the slightest muscular reaction. It is the rule that the Faradic current will

not produce muscular response, hence its use under such circumstances even by the physician is useless.

Along with the electricity there should be used massage of the paralyzed limbs, and if the nutrition of the muscles does not improve under the stimulus of electricity and massage, then stimulating applications may be made to the surface of the limb, and for this purpose we prefer to use the capsicum plaster; placing around the paralyzed limbs strips of plaster about from ½ to ¾ of an inch in diameter, which are to be worn for two or three days and then renewed, and if after a reasonable space of time, the limbs do not improve under this treatment, then I advise the use of deep injections of strychnine, preferring the nitrate of strychnine as less irritating, using full dose, and giving one injection every day.

This treatment must be persisted in for months, even though but little if any improvement is at first noticed, but even the most unpromising cases will occasionally yield to the treatment if perseveringly pursued. The occurrence of deformities will require appropriate surgical treatment, but should not cause us to stop the use of remedial measures. During the progress of this treatment, the child should be encouraged in every possible way to use the paralyzed muscles, and, of course, every possible attention should be given to the hygiene of the patient, for that condition of living that results in the best general vigor, will be of the most service in correcting this special disturbance of nutrition.

ICHTHYOL IN SORE NIPPLES.

Dr. Oehren (*Therapeutische Monatshefte*, No. 2, 1892) recommends ichthyol in the treatment of sore nipples, and according to the following formula:

℞
Ichthyol.....gms. 4 (3j).
Lanoline.....
Glycerine..... āā gms. 5 (3j¼).
Olive oil.....gms. 10 (3ijss).

The advantages of this salve are: One application causes the terrific pains to disappear, the fissures quickly heal, without it being necessary to wean the child or to use a protective cap. The consistence is such that it is easily washed off after being applied, and at the same time the salve contains nothing that will harm the child.

Society Reports.

CLINICAL SOCIETY OF LOUISVILLE.

Stated Meeting, June 7th, 1892.

The President, Dr. P. Güntermann, in the Chair.

FREE DRAINAGE IN PURULENT PLEURITIC EFFUSION.

Dr. J. M. Krim: In substantiation of the belief in free drainage, I simply want to exhibit a case upon which this was practiced, the patient suffering at the time from purulent pleuritic effusion. I further wish to state that I believe this is the only reliable mode of treatment in all such cases. This girl when seven years of age had an attack of typhoid pneumonia, and about four or five weeks after she was convalescent from that trouble, the left side of the chest began to bulge and swell, with difficult respiration, which continued until it made a considerable bulge right where you see the scar. It was then opened and a small drainage tube inserted, which was allowed to remain for six months. She had some fever and rigors occasionally, but not to amount to anything. The patient is now in very good health, except that there is a little dullness on percussion over that side. She is now about fourteen years of age, and the menstrual function has been established.

Case No. 2.—This is also a case that passed through a siege of pleuro-pneumonia, of about five weeks' duration. About four weeks after he was taken with pneumonia, there was considerable bulging of the right side, with difficulty in respiration, temperature varying between 100° and 103°, and more or less cough. After the respiration began to be more impeded, I used the aspirator and drew off about a pint and a half of dark greenish purulent substance, which gave him considerable relief. In about two weeks it had again filled up and another aspiration was done, and about a half pint of liquid drawn off. In about three weeks it commenced filling up again, cough became more severe and one day in stooping down the abscess broke into the broncha, and he expectorated a great quantity of the material. I intended to put in a drainage tube on No-

vember 10th, and the abscess bursted on the 9th. Patient has improved ever since. It was about nine weeks after the first aspiration before it bursted.

Case No 3.—I am sorry that the subject of this case was not able to be present this evening. The patient is a young lady aged twenty-two years whom I saw about the middle of October last suffering with an acute attack of rheumatic trouble. All the large joints were involved, and she had been sick about two weeks before I saw her. I made a thorough examination, found she suffered with mitral regurgitation in addition to the rheumatic trouble, and she told me she had suffered with heart trouble since the first attack of rheumatism about ten years ago, which has occurred every two years since. Two weeks after she came under my treatment, I found there was considerable œdema on the left side with impaired respiration and complication of the pleura. I thought it was possibly due to some conditional heart trouble. I put her under treatment with salicylate of soda with the hope that it would remedy it, but the side continued to enlarge. I used the aspirator and drew off about a pint of fluid; it was not a purulent matter however, just a plain pleuritic effusion. She recovered from this and about six weeks afterward the right side began to get large. I called Dr. Bailey in consultation and he thought it was probably due to effusion. We used the aspirator and drew off about a pint and a half of purulent substance; it filled up again in about three weeks, and I then used a large trocar inserting a drainage tube through the canula after withdrawing the trocar. The tube remained in about two months draining off everything, and she fully recovered. I cannot understand why it should have been simply pleuritic effusion of the left side, and purulent on the other side.

Case No. 4.—This is a case of tubercular origin. I saw the patient for the first time in March, 1890; there was consolidation of the right lung, temperature varying between 101° and 103.5°. About three months later he had a slight hæmorrhage, from which he made a fairly good recovery. In May, 1890, there was considerable œdema on the right ride; he was aspirated and about a pint of dark greenish purulent substance drawn off. In about three weeks we had to aspirate a second time. On the 3rd of July, last year, we made a resection, taking out about an inch of rib, removing about half a gallon of the purulent material, and the discharge has continued ever since. He is now gaining in flesh and is looking better than he has for quite a while. There is not much tube inserted now, about half or three-quarters of an inch; the opening is gradually closing up; he does not have any hectic condition. I had the discharge examined microscopically and chemically, and the results showed that it was tubercular trouble. The patient is now twenty-six years of age; two sisters have died with tubercular trouble; both father and mother are healthy. You will notice in walking he has a peculiar gait, slightly favoring the right side.

Case No. 5.—There is another case that I want to report, that unfortunately died. It is a case of diabetes; patient had been suffering about six months before I was called. An examination of the urine revealed about ten per cent. of sugar. He had been voiding about six to ten pints of urine in the twenty-four hours. His right side was considerably œdematous, breathing difficult, hectic condition, etc. I aspirated him and drew off about two pints of fetid, dark, bloody looking liquid, and it filled up again in about two weeks. I then used a trocar, inserting a small drainage tube, which gave him considerable relief, but unfortunately the man died in the course of about ten days after drainage was put in, I suppose from gangrenous condition of the lung. I simply wanted to make the statement that I would substantiate all those who advocate free drainage. After the diagnosis had been thoroughly made, I certainly would not attempt a second inspiration, but would use free drainage. It might be modified sometimes, and instead of making a resection, introduce a trocar and rubber tubing through the canula.

DISCUSSION.

Dr. T. Satterwhite: I would like to ask Dr. Krim what kind of a tube he used in the first case he presented.

Dr. J. M. Krim: I used a plain rubber tube. It was open about six months, and discharged I suppose about ten ounces when opened.

Dr. J. A. Ouchterlony: Referring to the case of tubercular trouble exhibited by Dr. Krim, I would like to enquire if

there were any tubercular bacilla in the sputa before the operation.

Dr. J. M. Krim: Yes sir, all the characteristics of tubercular trouble. The discharge, however, did not have any fetid odor until the last couple of months.

Dr. J. A. Ouchterlony: What is the patient's temperature at the present time?

Dr. J. M. Krim: Temperature is about 99°, sometimes a little more, then again normal.

Dr. J. A. Ouchterlony: Have the bacilla disappeared from the discharge now?

Dr. J. M. Krim: No sir, they have not.

Dr. T. Satterwhite: I would like to ask if the patient has any cough at this time.

Dr. J. M. Krim: He has some cough, principally in the morning, and some little expectoration, The discharge is very slight during the day, increasing at night when the patient lies down.

Dr. J. A. Ouchterlony: I regret very much that I did not hear report of the other cases but the one I was fortunate enough to see is certainly exceedingly interesting, and it suggested to my mind some points concerning the combination of pleurisy with pulmonary tuberculosis. We are aware that pleurisy in connection with tuberculosis is quite common, and I would mention in passing that when it does occur, save in the form of plastic, it is generally of a suppurative variety. Under such circumstances not only is it good practice to do as Dr. Krim suggests, to open the pleural cavity and establish drainage, but it seems to me that it affords most excellent opportunity for bringing the anti-tuberculosis treatment to bear in a manner that cannot ordinarily be done, attacking the disease by means of copious washing out with carbolized solutions. I think we should continue to wash out the cavity under such circumstances with carbolized solutions of the proper strength, as long as any remains of the cavity exists. That there are tubercular processes going on in the pleuritic cavity, as well as in the lung itself, is proven by the fact that tubercular bacilli were found.

As to removing a portion of rib in tubercular pleurisy—I do not know that it is entirely free from objections, because it may lay the patient liable to danger of infection of the ribs with tubercular bacilli. My preference in a vast majority of cases of suppurative pleurisy that I have seen would be decidely in favor of using a large rubber tube. Indeed, I have not had a case in my practice within the last ten or twelve years where it has been necessary to resort to the exsection of a rib. I devised a self retaining rubber tube much larger than the largest trocar, by means of which the opening can be kept as fully pervious as desired, and affords a most excellent opportunity for washing out the pleural cavity. The ordinary soft catheter used I do not think sufficient, as a rule, and it has the disadvantage that there is always a possibility that the catheter may slip into the pleural cavity. Such accidents have occurred in a number of cases, and have necessitated the performance of an operation of some magnitude in order to correct them. The tube I have devised has a flange which prevents it from entering the cavity.

Dr. J. W. Irwin: The remarks made by Dr. Ouchterlony seem to be about all that can be said upon the subject. With reference to the operation for removal of pus from the pleural cavity—several years ago I had made by Mr Armstrong an instrument for entering the intercostal space, which is quite narrow. It is very hard to get a canula of suitable size between the ribs. I had made a flat canula and trocar so that I could insert it between the ribs by elevating the elbow as far as it could be elevated, and in that way could get free drainage of the pleural sac very much easier than by ordinary means of aspiration, and I subsequently as Dr. Ouchterlony has just said, inserted a rubber drainage tube allowing it to stick out far enough so that it could not be drawn into the chest.

Now, as to the method of washing out the chest in consumptives—I have had considerable experience in that. I remember one case that I will mention briefly: The patient was a large fleshy man, (in the employ of a brewery), who had inherited consumption, and during the first year of the disease, he developed quite a sac of pus in the pleural cavity and it became necessary to evacuate it. I evacuated it in the manner described, and injected every other day from a pint to a quart of carbolized solution, 2½ per cent. of pure carbolic acid, into the cavity of the chest. He improved for a while very rapidly, and it seemed that

he would get well, but gangrene set in and he became rapidly worse and died. In another case that came under my observation, I used a three per cent. solution of tincture of iodine, injecting from a pint to a quart—it took that much to wash out the cavity—the same results followed as in the case mentioned. In both instances the washing seemed to produce a decided improvement for a short time, but subsequent results hastened death.

Dr. T. Satterwhite: Referring again to the first case exhibited by Dr. Krim: I notice that the opening was made rather high, and think it would have been beneficial if an incision had been made lower so as to have used a syringe from above downward. However, the results show that the child made an excellent recovery. I remember a number of years ago, a child about nine years of age had a very excessive effusion and I made a silver tube with a flange which was inserted and the cavity washed out regularly for two or three months. The child had the most excessive curvature of the spine that I have ever seen, resulting from collapse of that side, but by practicing inflation of the lung it evidently broke up the adhesions and and the curvature entirely disappeared. The second case reminds me of one that I saw some time ago in connection with one of the members of this society: There was very considerable fullness of the right side of the chest, the lower half or two-thirds. A portion of the rib (probably about two inches) was trephined expecting fully as soon as we did so, that pus would gush out, but no pus came. We concluded that we ought to put in a drainage tube but were at loss to know exactly what course to pursue. The next morning there was a very free discharge of pus, I suppose about two or three pints. My idea was that there was no effusion, but that it was an abscess of the lung. There was complete dullness, we could hear no respiration at all in the lower part of the chest, and there was also bulging so we diagnosticated pleuritic trouble. It came on in the way that these pleuritic effusious usually come.

Dr. W. T. Dulaney, (of Bristol, Tenn.):—I have had a little experience with this character of cases, not a great deal, but what I had came thick and fast. I had three cases within eighteen months about the year 1885; one was a very remarkable case, and illustrates the importance of washing and drainage. I will report them briefly:—The first subject was a young man about twenty years of age, very stout and vigorous previous to the attack to which I refer. About the first of January, 1886, he danced all night and soon after took a trip by rail and was subsequently attacked with what his physician (a very good one) called pleuro-pneumonia. I was not called to see him until May—found him suffering with general anasarca, very much swollen all over, could not lie down, breathing was very rapid, pulse over 140, left side of chest filled with fluid, and he was depending upon one lung for respiration. I did not have an aspirator at the time, but relieved his general œdema by puncturing his back, legs, etc., and in a day or two it all drained out. He was then in such condition that I could make a more thorough examination. We aspirated him about the eighth intercostal space behind, and drew off about eight pounds of pus having a sort of muddy appearance. Of course there was immediate relief from the distressing symptoms, pulse came down to normal in less than twenty-four hours. In two weeks, he was as full as ever; we operated again drew off this time about nine pounds of pus. The cavity was thoroughly washed out at each aspiration with carbolized water. Two weeks after the second aspiration he was fuller than ever; we used a trocar this time, but just as we were about ready to operate the abscess broke into the lungs and quite a quantity of very offensive pus come out by way of the bronchial apparatus. Previous to this there had been no odor about the pus whatever. We removed with the trocar about eleven pounds of pus, then inserted a small drainage tube, washing the cavity each day. In the course of two months while under treatment, we calculated that we removed from this patient about seventy pounds of pus. He made a good recovery and is now as strong and vigorous as ever, and is doing hard work as a plumber.

A short time afterward I was called to see a case that another doctor had tapped with a trocar, the patient was a little girl about two years of age, pale, thin, and as poor as anybody could be, financially—I merely mention this to show the surroundings. We used the trocar and drew off quite a quantity of pus and washed it out

thoroughly with carbolized water. The child made a good recovery.

The next case was a boy about eight years old, who had an abscess very low down, in fact, so low that I thought it possibly might be some hepatic trouble. It was on the right side. This child had always been in the habit of having his own way, and would not have it opened for about eight months, but it was discharging a little. The little fellow had become very much reduced, and I did not think he would ever get well. The abscess was opened in front, thorough drainage established, washed out with carbolized water every day, and the patient made a good recovery.

I regarded the first case as a very interesting one on account of the quantity of pus removed. The heart was dislocated, as far to the right side before the operation as it should be to the left in the normal state.

Dr. W. O. Roberts: I have had quite a large experience in the treatment of empyema; have seen only one case of true empyema die after drainage was established. That case occurred in the city hospital and was doing well, when a case of erysipelas was brought into the hospital, and this patient among others became affected and died. In the majority of my cases the trouble has been on the left side. I have seen two cases in which there was spontaneous opening, and in each case it occurred high up in the region of the nipple and would only drain, of course, when the fluid reach a level with the opening, or the patient would lie down. I operated upon one of these patients a few weeks ago. He was a graduate of the University. In this case the empyema was on the right side. An opening was made in the seventh intercostal space, and he recovered without an untoward symptom.

In regard to the removal of a portion of ribs—my rule has always been whenever I can insert my little finger between the ribs, and that is, when there is sufficient space to admit of the introduction of a large sized tube, no interference with the ribs is necessary. But where this cannot be done it is then necessary to remove a section of rip. As to the use of the aspirator, I think the cases reported this evening prove the folly of attempting to treat or cure these cases by use of the aspirator. They invariably refill. The aspirator, I think, is only of use as a means of diagnosis. I believe an opening ought to be made just as soon as pus is discovered. Another point of great importance is the washing out of the chest: The weight of authority is against washing out the pleural sac, unless there is evidence of fetid discharge. As long as the discharge is sweet, it is not necessary to wash out the chest. There is a great deal of danger in washing the pleural cavity when you distend it to any great degree. A number of cases of sudden death have occurred from over-distension of the pleural sac. A point of considerable importance in the treatment of these cases after a tube has been introduced, is the use of an abundance of absorbent gauze, (not cotton but gauze) so that every particle of discharge may be absorbed as soon as it comes to the mouth of the tube. Recovery in many of these cases is delayed by neglect of this provision.

Dr. J. A. Ouchterlony: One reason for using the aspirator is to get immediate relief, when the patient is suffering with great interference either of respiration or circulation.

Dr. J. M. Krim: Concerning resection of the rib—I cannot see anything wrong about this. In all cases that I have treated and others that have come under my observation, I have never seen any bad symptoms or results from resection; still, I am inclined to do just as Dr. Roberts states, and as before mentioned by me, if you can introduce in the intercostal space a large sized trocar and so establish drainage, it might sometimes be preferable to pleurotomy. But I do believe where there is no chance to get a good sized trocar in between the intercostal space, that resection is not going to do any harm.

In regard to washing out the cavity:—In none of the cases I reported to-night was there any washing out done, except in one or two instances where the discharge had become offensive. As long as there was no fetid discharge the cavity was not washed, and all the patients improved very nicely.

Dr. J. A. Ouchterlony: My remarks were especially in reference to the last case exibited by Dr. Krim, which is a case of tubercular suppurative pleurisy. I do not think there can be any doubt that having tuberculous fluid flowing over the porous

structure of the rib, lays it liable to tuberculous infection.

Dr. W. O. Roberts: When it becomes necessary in tubercular trouble, to remove a portion of rib, would it not be a good idea to have the ends of the bone cauterized with the hot iron?

Dr. J. A. Ouchterlony: There is one objection to the removal of a portion of rib that I have noticed very frequently —and I have seen a great many cases of pleurisy, with effusion, both suppurative and non-suppurative—it is this, new bone forms with great rapidity, and the tendency to closure of the opening is very great by the formation of bony material. I have had cases under my care where exsection of a piece of rib has been made, and where the opening has been reduced to a minimum in a very short time. With me the point has always been whether it was not better to resort to the least severe operation if it will do; of course, if it is not adequate to meet the indications of the case, why then remove a piece of rib by all means.

Dr. W. T. Dulaney: Last fall a young man, conductor on a freight train, in Virginia, was shot by a tramp. I saw the patient about six weeks afterward and found the ball had entered at about the seventh intercostal space in front; there was general dullness all over the left side of the chest; he had no bloody expectoration and no cough, nor had there been any, but there was a little bulging at about the tenth rib behind. After consultation with the attending physician, Dr. Butler, we decided to make an incision there and when we reached the cavity, there was a gush of fetid pus, and serum, I suppose about two pints, and, upon enlarging the incision we found that the tenth rib had been broken by the ball passing through it, about two inches from the spinal column. While examining the wound as the pus and serum came out, the hole suddenly became plugged with a substance which looked like dead cellular tissue, or lung. I took hold of it and pulled out quite a quantity of the most effensive material that I have ever seen; it looked to me very much like dead lung tissue. About a double handful of it was removed. We found the ball just outside of the rib deep under the muscles of the back. The patient in the meantime had considerable fever. The wound was thoroughly washed out and the patient put to bed. In a day or two in giving him an enema, we were greatly surprised to see the water come out at the opening in the back. I had some doubts about this being the water used in the enema, so we used some colored water which also came out through the hole. The fever went down and the patient slowly recovered. He had fecal discharges from the opening for two or three months, and especially if they were fluid. The opening finally healed, and the man recovered though with impaired strength and diminished capacity.

Dr. W. O. Roberts: I would like to ask Dr. Dulaney if the material removed was a solid mass.

Dr. W. T. Dulaney: It may have been the result of hæmorrhage at the time the shot was received; it was a speckled mass looking like cells of the lung, in fact it looked like dead lung tissue. The hole was plugged up completely and we kept pulling out piece after piece of the offensive material, and, when we found the fistula, I did not know what was going to become of it. When the fecal discharges were a little thin or fluid, it would just pour out of the hole. I suppose it was the result of some inflammatory adhesions of the transverse colon to the diaphragm, which sloughed through.

DILATATION OF RIGHT SIDE OF HEART, WITH VALVULAR INSUFFICIENCY.

Dr. J. W. Irwin: I want to speak of a case that came to my notice some days ago. A man, a poor looking individual with a hospital shirt on, came into my office one day puffing and blowing, and said he wanted to be examined. He was forty-years of age and evidently had been an Irish laborer. He gave the history of having been at work for the Western Union Telegraph Co., raising a telegraph pole, and while doing so a spike pole that was resting against the telegraph pole with the spike end up, fell on his head striking on the upper portion of the occipital bone, producing some contusion over that region, and considerable swelling but no fracture. There was no laceration of the scalp and the injury did not give him much inconvenience as he continued at work for twelve days. He had some dull pain in his head and some little pain in his chest about the upper and middle third of the sternum; he also complained of some pain

in the region of the heart, of a dull aching character, but not continuous. There was no loss of appetite nor sleep; his digestion was good and when resting he felt comparatively strong. At the end of twelve days the pain in the head grew worse, and he then applied for admission to the city hospital. This occurred, I think, as nearly as I can remember, about the first of October, and he remained in the hospital ever since. On walking about, taking any considerable exercise, his face and lips would become of a purplish color, the veins in the face and neck becoming immensely enlarged, in fact the jugular veins appeared to be one inch in diameter. There was no pulsation nor murmurs in the veins. The veins over the sternum and over the chest were also greatly enlarged. One vein extending from the right inguinal ring to the axillary and sub-scapular veins was very much enlarged and tortuous. Some of the veins in the lower extremities were also enlarged, some of them varicosed. When the patient stooped over, his face, hands, arms, finger nails, and palms became purple in color. When standing erect the face became quite blanched, and the veins normal in size. His pulse was strong and full when standing erect, put when stooping forward the pulse grew very feeble on both sides. When in a stooping position or upon any exertion, he had considerable dyspnœa. He had a hacking cough without any expectoration; he complained of some dull headache at times, which was made worse by stopping over. Exertion also caused his head to ache. I examined the chest by percussion, found increased dullness over the region of the heart, extending pretty near to the ensiform appendix of the sternum. The sound of the mitral valves was short and sharp and heard a little toward the right of the left nipple. When stooping forward the sounds on both sides became muffled, and a faint blowing sound could be heard on the right side. There was no evidence of aneurism. Pressure over the region of the liver caused enlargement of the supra-clavicular veins and also the vein entering the inguinal ring that I have mentioned. The man is not strong, that is, he is physically strong enough, but on taking any sort of exercise he pants for breath. Food improves his condition very much. In other words, in half an hour after dinner he seemed much better, he could walk or stoop without causing any dyspnœa. I gave him two ounces of whisky which had the same effect on him as food. It was evident that both the food and whisky increased the power of the heart's action. I will state here that he gave the history of not being an intemperate man, he took a drink occasionally, said he had been a laborer for thirty-six years. He had never done any very hard work, and to use his own expression, had "never abused himself in any way." Never had any venereal disease. I diagnosticated dilatation of the right side of the heart with insufficiency of the tricuspid valves. Time will not permit my going into differential details. I wish further to say that I had his urine examined and found it to contain a small amount of albumin, but no casts. There was slight œdema about the eyes and ankles.

CASE OF SPINAL INJURY.

Dr. W. O. Roberts: I saw a man day before yesterday, a laboring man, thirty years of age. Last August he was loading a wagon with logs, the wagon was at the time about half full. He says that he was about eight or ten feet from the ground, while standing on the wagon pulling a log up with some kind of rope attachment, the rope broke or gave way, and he fell backward striking on his shoulders; was insensible for only a few minutes. He said when he came to himself he found that he had lost all muscular power of the body, from the neck down. He was seen some little time afterward by a physician and upon examination it was found that he had not only lost all power of motion but also of sensation, from his neck down with the exception of his shoulders and arms. He has remained in about the same condition up to the present time. He can raise his arms up, bend his elbows, but cannot bend his fingers. He has sen sation in his arms, also upon his body on a level with the lower boundary of the axillary space; below this point there is no sensation and no motion. There has not been at any time any ecchymosis or local evidence of contusion or mark to show where he struck the ground. Urine runs from him as fast as secreted; he has no control over bowels; when he has diarrhœa it just trickles from him all the time, and when his bowels are constipated, the nurse has to take the fecal matter away with the

fingers. His intellect is as good as it ever was.

Upon examination I could find no deformity whatever about the spine; between the seventh cervical and the first dorsal he is sensitive to the touch, but not nearly so much so as he was shortly after receipt of the injury. He has four large bed sores, his legs at first were perfectly straight and helpless, but for three or four months the muscles have been contracting until now there is marked flexion at the knee and at the hip, and it is impossible to straighten the legs. Before this occurred he says that there was considerable œdema in both legs; there is no evidence of that now, in fact his legs are very much shrunken. It is a question in my mind as to the nature of the injury, and as to the advisability of an exploratory operation to see whether or not there is any fracture of the lamina and if such can be found, whether its removal or elevation if depressed, would be of any benefit to him. There has been no priapism.

SYPHILITIC ULCERATION OF THE RECTUM.

Hahn (*Deut. med. Woch.*, January 28th, 1892) reports a case of syphilitic ulceration of the rectum in a woman, aged 33; there was also widespread ulceration in the ileum. At the necropsy the mucous membrane was found to be of a blackish green color, and extensively ulcerated for a distance of 16 cm. from the anus, with but few islets of intact mucous membrane; most of the colon was unaffected. In the ileum, at about 1.5 m. above the ileo-cæcal valve, there were eleven large ulcers with thick callous edges, and at 25 cm. above the valve a narrowing of the gut extending over 8 cm. There was amyloid disease of the kidneys and spleen, and also periosteal thickenings over both tibiæ. Anterior colotomy had been successfully performed during life, and there were free evacuations through the opening. The vomiting, however, persisted, and the author would attribute this to the renal disease. Hahn belongs to those who think ulcerative proctitis (occurring almost exclusively in women) is seldom really due to syphilis. After other measures have been tried, extirpation of the rectum and colotomy alone remain. Some cases, when of limited extent, can be cured by the former procedure.—*Brit. Med. Jour.*

Selected Formulæ.

FOR HYPERIDROSIS.

For the treatment of hyperidrosis in general, and for sweating of the feet in particular, Brocq (*Jour. des Maladies Cutan. et Syph.*, April, 1892) believes that the following drugs are of service:

℞ 1. Naphtol..... 5 parts.
Glycerine..... 10 parts.
Alcohol.....100 parts.
M. Sig.—Apply locally twice a day, after which a powder composed of two parts of naphtol and 180 of starch is placed between the toes.

℞ 2. Permanganate of potassium.... 3 grammes.
Talc.....40 grammes.
Subnitrate of bismuth.....45 grammes.
Salicylate of sodium..... 2 grammes.
Rice powder.....60 grammes.
M.

Or,

℞ 3. Permanganate of potassium....10 grammes.
Talc..... 5 grammes.
Subnitrate of bismuth.....25 grammes.
M. Sig.—Either powder to be applied every morning.

℞ 4. Sulphate of quinine..... 5 parts.
Alcohol at 6°.....100 parts.
Tannin..... 1 to 3 parts.
Alcohol at 50°.....250 parts.
M. Sig.—Apply after the feet have been washed, to be followed by this powder:

℞ 5. Salicylic acid..... 3 parts.
Starch.....10 parts.
Pulverized talc.....87 parts.
Pulverized alum.....45 parts.

℞ 6. Perchloride of iron.....30 grammes.
Glycerine.....10 grammes.
Essence of bergamot.....20 drops.
M. Sig.—For two days previously the feet are to be washed with a cold infusion of walnut-tree leaves, and on the third day the above mixture is applied.

℞ 7. Tincture of belladonna..... 25 grammes.
Cologne water..... 120 grammes.
M. Sig.—Two or three frictions per day.

FOR ALOPECIA.

Quinquaud (*L'Union Medicale—Journ. des Malad. Cutan. et Syphil.*, April, 1892) recommends the following topical application:

℞ Biniodide of mercury..... 0.20 gramme.
Bichloride of mercury..... 1.00 gramme.
Alcohol at 90,..... 40.00 grammes.
Distilled water.....250.00 grammes.
M. Sig.—The hair is cut short; then every day, after a good shampoo, the above solution is to be applied, night and morning. In the mean time frictions may be made with a liniment composed of: Balsam of Fioraventi, 100 grammes; camphorated alcohol, 100 grammes; ammonia, 6 grammes. For a general tr-atment the same author advises the administration of cod-liver oil during the first three weeks of each month, and five to six drops of Fowler's solution, per day, during the fourth week. The treatment is to be continued while the hair remains fragile.

FOR CHAPPED HANDS.

The following mixture, according to Baelz (*Med. chir. Centralb. Pharm. Post*, No. 52, p. 1137, *Journ. des Malad. Cutan. et Syphil.*, April, 1892), is of service:

℞ Caustic potassa..... 0.5 gramme.
Glycerine.
Alcohol, of each.....20.00 grammes.
Distilled water.....60.00 grammes.
M. Sig.—After washing the hands with warm water, the mixture is to be rubbed once every twenty-four hours.

P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor.
(Professor of Physiology, University of Penna.)

BUSINESS OFFICES:
29 to 35 North Tenth Street, Cor. Filbert.

EDITORIAL OFFICE:
Southeast Cor. 36th and Woodland Ave.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00

REMITTANCES should be made payable to THE MEDICAL AND SURGICAL REPORTER, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

—o—

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates).... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt **"The Medical and Surgical Reporter"** and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts.....$1.50 each.
Bovine Points or Quills..... 1.00 a doz.
Humanized Crusts..... 1.00 small.
Humanized Crusts..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

☞Please accompany orders with the money, and address all communications to

THE MEDICAL AND SURGICAL REPORTER,
P. O. BOX 843, PHILADELPHIA, P A.

Leading Articles.

THE PROPHYLAXIS OF PUERPERAL FEVER.

Dr. J. Veit, is one of the most recent numbers of the *Berliner klin. Wochenschrift*, essayed to answer this question in the following sentence: "In spite of the value and usefulness of antiseptics, the percentage of women dying from puerperal infection remains high even where no operative procedure has been undertaken; it must, therefore, be concluded that the too frequently resorted, to internal examinations practised by the physician during or after labor exert a harmful effect upon the patient, and in themselves constitute the medium of infection.

Viewing the matter from a similar standpoint, already a large number of eminent obstetricians both here and abroad have raised a note of warning against unnecessary examinations of the genital tract during childbirth.

Litzmann, the German obstetrician, allows the students at his clinic only to make external examinations, finding that the slight loss of practical experience is more than compensated for by the lessening of the death-rate.

The most recent communications from the pens of Credè and Hegar are practically only repetitions of these warnings. Leopold has also come to the conclusion that internal examinations should be avoided whenever possible, and adheres strictly to this rule in his practice. He states from actual experience that the mortality from childbirth can be reduced to a minimum if internal examinations are avoided.

The *Deutsche med. Zeitung* in referring to the subject, states that in cases of normal labor internal examinations can be entirely replaced by careful external examinations, and that the former should only be undertaken when special indications are manifest.

We have touched upon this subject not only on account of its vast importance, but because it has recently been most actively discussed by our European contemporaries; for abroad, as here, it has been the practice of most physicians to make an internal examination as soon as they reach the bed-side. According to these recent investigations, during the period of dilatation of the cervix, an internal examination should only be undertaken under the following circumstances: First, in cases where the condition of the patient is greatly impaired—as in eclampsia, nephritis, fever, bad circulation, etc.; second, in cases where there are local disturbances—hæmorrhage, abnormally painful labor, or an abnormally long period of cervical dilatation; third, in cases where an external examination reveals an abnormal condition—such as the head of the fœtus over the pelvis in primiparæ, or after the rupture of the amniotic sac in multiparæ, an abnormal enlargement of the lower uterine, segment, rupture, lessening of the fœtal heart sounds, or abnormal position of the fœtus.

During the period of expulsion an internal examination is only admissible under the following circumstances: First, in cases of general derangement—such as fever, bad pulse, great excitement, eclampsia, and nephritis; second, in cases of local derangement—such as delayed rupture of the amniotic sac, hæmorrhage, insufficient labor, or retarded delivery; third, in cases of an unlooked-for change in the position of the fœtus, abnormal distension of the lower segment of the womb threatening rupture, lessening of the fœtal heart sounds, and displacement of the fœtal head above the pelvis.

In order to be able to restrict the internal examination of parturients to the above named conditions, it will, of course, be necessary to submit the patient to a careful external examination, and indeed lay greater stress on the latter than is now generally done. It will also be necessary for our obstetrical clinics and schools to give their students more exact data regarding external examinations than is now generally done. This being accomplished, the results of a limitation of the internal examination of parturients will be speedily felt.

TREATMENT OF ABSCESS OF THE LIVER.

Fontan (*Rev. de Chir.*, February, 1892) holds that a simple incision is not always sufficient, even when very large, to effect a cure of hepatic abscess. Scraping of the walls of the abscess was advocated as a desirable addition to incision. The scraping, it was stated, should be done with a blunt curette, guided by the index finger passed into the interior of the abscess. Two cases were reported in support of the author's opinion that such treatment is not likely to cause any serious hæmorrhage, and that it favors rapid and complete cure. In the discussion, Pozzi, whilst granting that the method might enable the surgeon to discover and open a second abscess, said this advantage would not compensate for such probable dangers as hæmorrhage and opening of the biliary passage. Monod considered the method not only dangerous, but also useless. He quoted cases to show that incision followed by drainage would suffice to bring about a cure of the abscess. In one of these cases, however, the ultimate result was not satisfactory. After three unsuccessful exploratory punctures, a fourth made in the intercostal space revealed the presence of pus in the liver. Monod, after removing a portion of rib, made a free incision into the abscess and drainage the cavity. The condition of the patient improved for a time; but subsequently the temperature rose, the diarrhœa became more profuse, and death took place six weeks after the operation. The original abscess, which had been incised and drained, was found at the necropsy to be quite closed, but there remained two other collections—one near the convex surface, the other near the inferior surface of the liver. The presence of one or more other purulent deposits is usually the cause of failure of incision in the treatment of hepatic abscess. Unfortunately, Monod states, it is very difficult to determine the presence of such multiple abscesses.—*Brit. Med. Jour.*

Book Reviews.

DISEASES OF THE URINARY APPARATUS, PHLEGMATIC AFFECTIONS. By John S. Gouley, M. D., Surgeon to Bellevue Hospital, New York. New York: D. Appleton and Co., 1892.

The scholarly attainments of this distinguished New York surgeon have never been shown to greater advantage than in this, his latest book. Every American surgeon is familiar with the thoroughness and depth of Dr. Gouley's professional knowledge, his clearness of expression, exactness of statement, and beauty of style; and those who have valued his previous writings will read this contribution with great satisfaction. The subject is presented in its broadest and most comprehensive aspect; principles rather than technique and methods being dealt with. It may truly be said that this book is a fitting evidence of a long life of usefulness, clinical research and experience. In every page we clearly read that the author has recognized above every other consideration the paramount value of the great principles which underlie the diseases of which he speaks, and that he conscientiously endeavored to trace as definitely as our knowledge will permit the true pathological states concerned in their production. It is this admirable foundation which gives special value to his work.

The term *phlegmasic affection* is his own, and by it he means "a morbid process, one of the local nutritional changes which, when visible and tangible, is ordinarily characterized by heat, redness, swelling, and pain, and which is now believed by many pathologists to be generally caused by microbic invasion. "Another term which will attract considerable attention is *allotrylic affections*, meaning, as its derivation suggests, "morbid states caused by the lodgement of foreign substances in the organism?"

The division the author makes in the general pathology of the urinary apparatus cannot be too highly praised. It is complete in itself, and its application to special diseases of the urinary apparatus is simply perfect. No one can study too carefully this excellent chapter. It is in fact the foundation of all that follows, and if the student gets the truth contained in it firmly fixed in his mind he will have a solid basis for any subsequent pathological considerations which may logically be deduced from the principles here laid down.

Among the special considerations none is more interesting, more valuable and better prepared than the one devoted to cystitis; the remarks upon its treatment being worthy of special attention. The author is a strong opponent of infra- and supra-pubic cystotomy for the relief of chronic cystitis with contracture of the bladder. In these cases he believes that the best method of cure is by hydraulic dilatation of the bladder. Concerning this he remarks: "There is no curative power in rest and drainage of the bladder in the case of cystitis and contracture. * * * The prescription of long rest to the bladder in these cases does not seem rational, since it is well known that the prolonged immobilization of any part so surely leads to its permanent contracture. The muscular walls of the bladder need be exercised in cases of cystitis with contracture which has not become permanent, and this exercise is attainable by hydraulic expansion, which gradually restores the bladder to its normal suppleness and capacity."

In a book like this, every part of which is finished, it is useless to attempt to give more than an idea of its general characters, which has been very imperfectly attempted here. Every surgeon should read it, for we are sure that there will not be disappointment.

THE SUBCUTANEOUS USE OF IRON IN NERVOUS TROUBLES.

Rosenthal (*Pest. Med. Chir. Presse*) advises this method of administration. He has detected the metal in his own urine within thirty to forty minutes after injection. He recommends two preparations: Ferrum peptonitum, produced by adding a solution of pepsin to one of ferric chloride, producing a powder soluble in water, which is given in doses of one syringeful of a 10 per cent. solution every other day; and ferrum oleincum, given in the same dose in a 5 per cent. solution in olive oil. The former is preferable. He recommends this method in delicate neurasthenic individuals, and in the asthenic dyspepsia often complicating anæmia, in which small doses of iron often produce severe digestive disturbances. Unpleasant effects have not been noticed.—*Deutsche Medic. Wochensch.*, No. 30, 1891.

Periscope.

THERAPEUTICS.

THE DRY POULTICE IN THE TREATMENT OF EPIDIDYMITIS.

In the *Journal of Cutaneous and Genito-Urinary Diseases*, Dr. George Emerson Brewer reports the successful treatment of a number of cases of epididymitis by the "dry poultice." This name is given to a dressing of cotton wool applied thickly over the inflamed portion of the organ and extending on to the healthy skin. This is covered with thin rubber tissue held in place by a snugly applied gauze bandage and the whole placed in a suitable suspensory. Pains rapidly subside, the inflammation disappears, and the organ returns to its healthy state.

TRANSFUSION OF SALT SOLUTION INTO PERITONEAL CAVITY IN COLLAPSE.

Johnson-Alloway (*Montreal Med. Jour.*, February, 1892) removed the ovaries of a woman, aged 42. They were non-adherent, nodular, and about the size and shape of a human kidney, stony hard, and attached to the uterus by a short pedicle. Three gallons of a dark brown limpid fluid flowed away from the peritoneal cavity. There was evidence of secondary deposit in the mesenteric glands and elsewhere. Eight hours later the patient was pulseless, restless, sighing, and almost senseless; the shallow respiration became gasping. Johnson-Alloway believed that this condition was probably due to the sudden withdrawal of a great quantity of fluid, which had removed firm and constant pressure from the heart and large abdominal vessels. He accordingly transfused about three quarts of sterilized salt solution (tempereture 110°) into the abdominal cavity through the glass drainage tube inserted at the operation. The patient immediately began to scream and vomit violently. The tube was removed, and the opening closed by firm packs of cotton-wool. In about five minutes the radial pulse became full. Some hours later the abdomen was as flat as when the patient left the operating table. The highest temperature (second day) was 101.5°. The patient left the hospital within four weeks. On account of the rapidity of its action peritoneal transfusion is preferable to hypodermic injections or enemata of salt solution.—*Brit. Med. Jour.*

PILOCARPINE IN THE STATUS EPILEPTICUS.

Dr. Kernig (*La Semaine mèdicale*, No. 11, 1892), was called to a case of a young girl who was suffering from status epilepticus. A subcutaneous injection of two centigrammes (one-third of a grain) of the hydrochlorate of pilocarpine produced copious perspiration, followed by complete and definite arrest of the convulsions. In about an hour œdema of the lungs apparently threatened, together with collapse. Fortunately, these disquieting symptoms disappeared, the pulse rose in force and frequency, and the patient fell into a calm and reparative sleep.

THERAPEUTIC NOTE ON ALOPECIA AREATA.

Bulkley (*Journal of Cutaneous and Genito-Urinary Diseases*, February, 1892) claims for the treatment reported in this paper greater success than other methods have attained in his hands. It is the very thorough application of a 95 per cent. solution of carbolic acid to the bald areas. He makes a small cotton-wool swab, dips it in the acid and lightly paints the affected spot, afterwards gently and firmly rubbing it in for some seconds. The skin is whitened, in a day or two becomes slightly inflamed, and within a week or ten days sheds its epidermal layer. The process may be repeated in two or three weeks; and has never given rise to accident—such as blistering. No larger area than two or three square inches should be attacked at a sitting.

THE DISADVANTAGES OF HOT-WATER BOTTLES.

The custom which so largely prevails mainly among ladies of using hot-water bottles in bed for the purpose of warming their feet, time-honored as it is, cannot after all be said to have had much to commend it. Indeed, there is a good deal more which can be urged against it than can be said in its favor. Ladies who resort to the habit, for habit it soon becomes in the majority of instances, suffer from cold feet, a condition which it is needless

to say does not particularly conduce to the wooing of sleep. But cold feet is a symptom which should not be left to be dealt with at the end of the day; on the contrary, those in whom it occurs should bear in mind that in ordinary health the proper remedy for this condition is exercise. Nothing tends more to cause "cold feet" than sitting about the house all day, or reducing the daily exercise to a minimum amount, either on account of laziness or feebleness of will-power for exertion. Some persons console themselves with the reflection that they were born with cold feet, and on these grounds hold that it was always intended that they should warm them by artificial means, thus ignoring the necessity which exists for exercise. Hot bottles, too, used in this way become a fertile source of chilblains, and, moreover, are not devoid of danger. We heard the other day of two cases in which the ladies using them were seriously scalded by the cork of the earthenware bottle containing the boiling water suddenly popping out. This brings us to the consideration of whether hot bottles should be used at all, and we think the answer should be in the negative. The best way of warming cold feet at night is to clothe them with warm woolen socks or stockings, which may be slept in. By this means the temperature of the feet is gradually raised, and is equably maintained throughout the night without trouble or risk. Another useful plan is to raise the feet on a pillow about two inches above the knee, so as to facilitate the return of the blood through the veins of the limbs.—*Med. Press.*

ANTIPYRINE.

M. B. Martin, in *L' Union Mèdicale*, Nos. 125, p. 565; 126, p. 577; 128, p. 601, adds much to the statements of the uses of this drug as found in the treatises on therapeutics, believing that its antipyretic properties have over-shadowed others equally valuable. It is useful in hæmorrhage, in that it locally will contract blood-vessels, and, indeed, it is an antiseptic. During operations a one-to-twenty, in epistaxis one-to-five, in coryza one-to-thirty solutions are used. It is valuable in laryngeal affections (catarrhs, stridulous laryngitis), asthma, broncho-pneumonia, pleuritic effusions, when given internally. As an anti-galactogogue, ten to twenty grains, several times repeated; for incontinence of urine (should be giving at 9 or 10 P. M.), for diabetes insipidus and true diabetes (up to a drachm daily); for uterine cancer (Cheron); and in dysemenorrhœa it relieves pain. Even the pains of labor are mitigated. Exophthalmic goitre, nocturnal pollutions, pains of tubercular meningitis, hemeralopia, asthma, either essential or of cardiac origin, distress of aortic aneurism, trigger-finger (subcutaneous injection) —all have been benefited; infantile diarrhœas (Saint-Philippe); with cocaine in obstinate vomiting (Struver). Some dermatoses, as urticaria, erythema nodosum, senile pruritus, and other conditions, where exceptional benefit has been obtained, complete the somewhat extensive list. The paper closes with a statement of the accidents that may be caused by this remedy.

ACONITE FOR SCORPION STING.

A correspondent from Durango, Mexico, says that formerly about one half of the children in the city died from the sting of the scorpion, but now nearly all the lives are saved, if taken in time, by the use of the strong tincture of aconite, of which 5 or 6 drops are put in a tumbler half full of water, and a teaspoonful given at frequent intervals.—*Ex.*

ALKALIES FOR THE INFLUENZA.

Based on personal experience, Crerar. in a paper read before a branch of the British Medical Association, fervently recommends potassium bicarbonate as an unfailing remedy for the cure of influenza. The doses administered by him being 30 grains every two or three hours. The advantages of this treatment are summed up by the author as follows: "1. If used before the attack, it prevents the disease. 2. It destroys the power of the disease within twenty-four hours, generally within four or six hours. 3. The strength is conserved, and the convalescence is short and satisfactory. 4. Sequelæ are conspicuous by their absence. 5. The death rate is reduced to a minimum. I have not had any death in more than one thousand cases. 6. It has more power over influenza than I have ever seen exerted by any method of treatment over any other disease, and I have had an extensive practice for upward of a quarter

of a century. 7. If adopted by the whole profession, it would make influenza non-existent in one week. 8. It rests upon a sound scientific foundation." The last two propositions certainly are very sanguincal and rather startling.

A NEW ANTI-RHEUMATIC.

Salophene is a derivative. It is obtained by treating para-nitrophenol with salicylic acid, reducing the nitrophenol by means of zinc and hydrochloric acid into an amide, and acting upon this with acetic acid. Salophene contains about 50 per cent. of salicylic acid, and exists in the form of thin scales, tasteless, inodorous, and with a neutral reaction. It is almost insoluble in cold water, and only slightly so when warmed. Upon the addition, however, of an alkali it readily dissolves. It is very soluble in alcohol and ether. It burns with a smoky flame, leaving no residue. In the stomach salophene breaks up into salicylic acid and acetyl para-amido-phenol. These substances are excreted by the kidney, and can be found in the urine. Salophene, owing to the presence of amido-phenol, is less poisonous than salol. According to Guttmann, it is a valuable remedy in articular rheumatism, given in doses of from four to six grammes a day in pill or in the form of compressed tablets.

MEDICINE.

RECURRENCE OF CARCINOMA OF THE BREAST

Dennis (*Medical Record*, February 27, 1892), in reviewing the conditions that favor the return of carcinoma in the breast, says, twenty-five per cent. of the cases operated upon fail to recur. The recurrence is influenced by the following conditions:

(1) By the period of time from the appearance of the growth to the time of operation, and places the average time at six months, because at this time little or no infection of the neighboring lymphatic glands has taken place.

(2) By the extent to which infiltration has taken place.

(3) By the radical character of the operation. The extensive operation is suggested from the fact that Küster had examined the glands removed in 117 cases of cancer of the breast, and only two cases failed to show no invasion.

(4) By the histological character of the carcinoma itself. Tumors showing structures departing but slightly from the normal are favorable cases, and the more embryonic the structure the greater the liability to recurrence.

(5) By the appearance simultaneously of carcinoma in both breasts. This condition, however, exists only in five per cent. of the cases.

(6) By the personal factors of the individual, such as age, sex, marriage, traumatism, race, etc.

The locality of the carcinoma has a marked influence on the recurrence after removal.

More whites die from carcinoma than blacks.—*Univ. Med. Mag.*

THE PROPER COURSE TO PURSUE WHEN A WOMAN WITH SYPHILIS COMES TO CONSULT YOU.

Professor Fournier has just given in one of his remarkable lessons the line of action to follow when consulted by a syphilitic woman. This varies with the social status of the patient. If *irrégulière*, that is to say a woman who is kept or a prostitute she must be told at once the nature of her ailment so as to put her on her guard against the danger of infecting others if she persists in maintaining relations with them. If on the contrary it is a married woman the line of conduct is much more delicate. To declare rudely that she is affected with syphilis is to risk, if the husband is the culpable one, causing domestic trouble, and separation in the family. If one simply gives a prescription without saying anything, this usually amounts to nothing for she does not fail to instruct herself upon the real nature of the drugs employed and thus learns the truth. Theoretically it is better to place the burden on the husband of keeping from the wife so far as is possible the nature of the disease which she has received from him. The husband must thus be taken into the case and entrusted with the direction of the care to be taken and the carrying out of the treatment. For this reason Professor Fournier does not advise giving the patient at the first visit a prescription which could awaken suspicion. A local

treatment without mercury should suffice, the patient must be told that there are certain points in the case which do not appear quite clear, and for which reason a conversation with the husband will be necesary, or that there are certain things you wish to recommend to the husband, and ask to have him sent to see you. If the woman is innocent, that is to say if she has had relations with her husband alone, she will readily comply with your request. From this time on you have only to come to an understanding with the husband keeping as much as possible from the knowledge of the wife the real nature of her complaint. However too much secrecy cannot be expected, for after a certain period of this prolonged and mysterious medication the woman begins to suspect the truth, but the object has already been attained, scenes of violence have been avoided which in the commencement would have been precipitated by a sudden discovery of the true nature of the disease and usually regrettable separations and divorces are avoided. But to act as we have suggested we must be quite sure of our premises. We must be assured that it is from the husband alone and not from some other that the contagion has come for in the opposite case it would be the same as saying to the husband "your wife has syphilis and as you haven't it, she must have contracted it from some one else." So as not to commit such a blunder care must be taken in speaking to the husband before having the full assent of the wife. If she is innocent she will have no reason to oppose the conference, if she is guilty, that is to say if she has had relations with other persons she will without doubt take you at once into her confidence.

SUPPURATION DUE TO PNEUMOCOCCI.

R. Condamin (*Lyon Mèd.*, February 7th, 1892) records a case of multiple suppuration, consecutive to a suppurative otitis, which presented characters different from those usually observed. The ear mischief developed suddenly during the course of influenza, and rapidly culminated in perforation of the tympanum, having been preceded by severe sore throat. Two days later the patient's temperature was high, and he had several rigors. An abscess developed on the dorsum of his left hand, which was opened two days afterwards. From this time a series of abscesses in different parts of the body, all subcutaneous and running a rapid course, developed. From fifteen to eighteen at least of these were observed, and in each case cultivations from them revealed the pneumococcus of Fraenkel in a state of purity. The common character of all these abscesses was their quiet development, without acute pain—in fact, they behaved after the manner of "cold" abscesses. The pus was very thick, yellow, and odorless; there was little tendency towards diffusion, each collection tending rather to become encysted. The rapidity of the disappearance of each after being opened by the thermo-cautery was most striking.—*Brit. Med Jour.*

SLOW PULSE.

Among the causes of slow pulse, Dr. D. W. Prentiss enumerates the following, saying that the causes which produce slow pulse may be classified as follows:

1. Diseases or injuries to the nerve centers, producing either irritation of the pneumogastric or paralysis of the sympathetic (accelerator) nerves of the heart.
2. Diseases or injury of the pneumogastric nerve, increasing its irritability.
3. Disease or injury of the sympathetic nerves of the heart, paralyzing them.
4. Disease of cardiac ganglia, by which the influence of pneumogastric nerve preponderates.
5. Disease of the heart muscle (degeneration), whereby it fails to respond to the normal stimulus.
6. The actions of poisons, as lead or tobacco, either on nerve endings or centers. The poison generated in salt fish.

Also the poison of certain febrile diseases, algid pernicious fever.

Another possibility is *malarial poisoning.—St. Louis Medical and Surgical Journal.*

CYSTIC DISEASE OF THE KIDNEY.

After reporting such a case recognized during life, Stiller (*Berl. klin. Woch.*, March 7th, 1892) discusses the diagnosis of this affection. Of the first importance is the recognition of a tumor of renal origin. This tumor appears clinically to be a solid one. Owing to the considerable

stretching of the capsule over the cysts no fluctuation is obtained; on the other hand if the cysts are insufficiently stretched, no tumor may be felt. Cysts in the liver not infrequently co-exist (in 18 out of Lejars' 62 cases). Fluctuation is not recognised in them even when unevenness of the liver surface can be made out. The age of the patient and the behavior of the disease is against carcinoma. The long duration of the disease almost without symptoms is against suppurating kidney such as is found in case of calculus, tubercle etc. Hydro- and pyo-nephrosis, or hydatid of the kidney, yield fluctuation. The sudden onset of uræmia and anuria in a patient previously without renal symptoms and who has a renal tumor, is in favor of cystic disease. A paranephritis may occur owing to rupture of the renal tumor. The fact of the tumor being bilateral is in favor of this disease, but clinically this is not usually recognized, although at the necropsy both kidneys are much more frequently found to be affected. The urine is usually abundant and limpid, with little albumin. The character of the urine is however only of value in the presence of other signs of the disease. The diagnosis is important, for among other things, extirpation of the kidney is contra-indicated, because the disease though clinically unilateral by far most frequently exists on both sides.—*British Medical Journal.*

NEURASTHENIA AND HYPER-ACIDITY.

The *Medicinisch-Chirurgische Rundschau* reviews an article by A. Pfannenstill of Stockholm in the *Nordiskt Med., Ark.*, on the connection between the above-named two conditions. Neurasthenia and nervous dyspepsia are, according to the writer, as frequently seen in Sweden as in other parts of the world. A valuable addition to the ætiology of these complaints is that all the cases observed by Pfannenstill belonged to the working classes, so that neurasthenia is certainly not confined to the upper classes of society, who are most exposed to the excitement of modern life. Of both complaints a primary and secondary form can be distinguished; but the latter, which is merely a symptom of other affections, especially hysteria, is much the more frequent. Hysteria is more often observed in connection with a general neurasthenia, in which the functions of the secreting nerves are always disturbed, and we may find in consequence hyper-acidity and hyper-secretion, or subnormal acidity, or even an entire absence of acid. The hyper-acidity is entirely due to an increase of hydrochloric acid. Pfannnenstill considers that this hyper-acidity is the result of an increase in the quantity of the gastric juice, and not merely of the hydrochloric acid, and that there is no decrease in the power of absorption. Increased secretion of gastric juice is probably the source of hyper-acidity in other affections of the stomach, and the reverse is probably equally true.—*Lancet.*

SO-CALLED GONORRHŒAL CYSTITIS.

Du Mesnil (*Virchow's Archiv*, Bd. cxxvi., Heft 3) proves that there is no specific gonorrhœal cystitis, the presence of gonococci in urine withdrawn by catheter being due to the back-flow of pus from the urethra into the bladder. Moreover, these organisms do not cause decomposition of the urine, so that their occurrence in an ammoniacal specimen does not imply that they were the cause of the change. It is probable that the activity of the cocci is hindered, if not entirely destroyed, by the urine.

CONTRIBUTION TO THE DIAGNOSIS OF TUBERCULAR MENINGITIS.

A well-built and well-nourished man of 40 became comatose at the moment of entering the hospital on foot, and so remained until death, two days later. There was rigidity of neck and spine and total absence of reflex irritability with the exception of the knee reflex. Pulse 80, R. 32, T. 99°. A diagnosis of meningitis was made. On further examination a moderate empyema of the right side was found. The pus was found to consist of fat globules almost entirely. As F. has pointed out, this is of itself almost pathognomic of a tubercular empyema, even without the demonstration of tubercle bacilli. Cultures demonstrated the absence of pyogenic germs. Autopsy showed a most extensive tubercular meningitis, both miliary and solitary nodules being extremely abundant. Tubercular foci were found in both lungs and supra-renal cap-

SENSORY AND VASO-MOTOR DISTURBANCE IN FACIAL PARALYSIS

"Dr. Frankl Bochwart, in an investigation into the conditions present in twenty cases of facial paralysis, found that in three there were disturbances of sensation and of the vaso-motor functions, in five of sensory functions only, and in two of vaso-motor only. The sensibility was only affected to a very slight degree, and sometimes the mucous membrane on the tongue and inside of the cheek was affected, and sometimes it was not. Occasionally also taste was affected. These sensory phenomena disappeared much earlier than the paralysis, but in one case in which the paralysis persisted there was diminished sensibility even after several years. The conclusion sought to be drawn from these facts is that the facial nerve in man contains some sensory and vaso-motor fibers; but of course it would first have to shown that the fibers of the fifth nerve had not also suffered when the facial nerve became affected."—*Lancet.*

HEPATITIS PARENCHYMATOSA BENIGNA.

S. Tama draws attention (*Nederlandsch Tydschrift v. Geneeskunde*, November 14th, 1891) by a series of cases to a well-defined form of parenchymatous inflammatory affection of the liver, which as a rule runs a favorable course. Talma regards the hepatic symptoms as secondary to an intestinal lesion, the liver being infected by way of the portal or lymphatic system, the latter being the more likely path. The affection may occur at any age; its onset is always marked by severe vomiting, accompanied either by constipation or diarrhœa, and in the course of a few days, varying from one to five, hepatic enlargement and tenderness are developed, respiration becomes purely thoracic, and the symptoms increase with or without a rise of temperature (in the severe cases the temperature rose to 104° F. in two, and to 102° in two other of the recorded cases), and the patient becomes extremly weak. The diarrhœa and vomiting cease in a few days, the urine is usually dark colored, and may contain a variable quantity of bile pigment, and there may or may not be slight jaundice. The hepatic enlargement is general, though circumscribed enlargements or bosses may occasionally be detected on the anterior surface, which may be as large as a hen's egg; their presence may mislead the medical attendant into the diagnosis of cancer or even abscess of the liver. Jaundice is seldom present, biliary obstruction or suppression is rare, and ascites has never been observed. The spleen is always enlarged, but diminishes in size as the patient improves. The symptoms in the less acute cases gradually disappear in about ten days or a fortnight, and recovery is generally speedy and uninterrupted. Hepatic nodules were found in two cases. Death resulted in two of the recorded cases. In one of these (a child aged 8) the spleen was *post mortem* found to be enlarged and firm in density the mesenteric glands and the portal and hepatic lymph glands were enlarged; there were no signs of recent or old peritonitis. The liver was much enlarged and very firm to the touch (weight 3,000 grammes). On the upper surface nodules were to be seen, regular in outline, with broad bases rising gradually from and merging into the surrounding hepatic tissue; on section there appeared to be no abnormality either in the liver or nodules, which latter were of the same density as the surrounding structures. Microscopical examination revealed an apparent increase in the quantity of the inter- and intra-lobular connective tissue; the liver cells appeared normal, and careful investigation of numerous sections displayed no further abnormalities.—*Brit. Med. Jour.*

PYREXIA AND ANTIPYREXIA, NERVOUS AND ARTIFICIAL.

Richter, in the *Brit. Med. Journal Supp.* (Inaug. Diss. Breslau, 1891), gives an account of some experiments made by him on pyrexia and antipyrexia. He first of all discusses the mechanisms by which the temperature can be lowered and concludes, as a result of calorimetrical experiments upon animals in which fever had been artificially induced by the injection of infusion of hay, that fever consists in a shifting of the heat-regulation mechanism. He therefore adopts Filehne's theory of fever. The difference between a nerve temperature and fever is next discussed and the author does not believe that there is in the brain any heat center, damage of which can cause fever. He regards the pyrexia which may be brought about by

damage to the corpus striatum, as quite distinct from fever, being only a temporary disturbance of the heat-regulating mechanism.

SURGERY.

CASE OF TUMOR OF THE PONS.

Dr. P. Watson Williams (*Bristol Medico-Chirurgical Journal*, Sept., '91.) A boy, aged six years, slightly hydrocephalic had for a time been observed to be growing tiresome and fretful. Occasionally he would tumble about and fall forwards, or go around like a toy, and then fall. Subsequent examination showed the face drawn to the right, internal strabismus; pupils large and inactive; left optic disc blurred, and gait unsteady. These symptoms became more marked. The left leg at times dragged, and later became partially paralyzed. Weakness and twitching of right facial muscles appeared and paralysis of the right sixth nerve. His irritability increased and there was a steady failure in strength. Vomiting only occurred twice. Then followed weakness of left arm, and later paralysis, dribbling, exaggerated left patella, tendon, reflex, and finally death from exhaustion. On autopsy the whole of the pons was found involved in new growth, being much swollen on its anterior surface and bulging above in the fourth ventricle. Both crura cerebri were likewise enlarged by the extension of the growth and the nerves in relation with the pons distorted and compressed. The third nerves of both sides were flattened and displaced, and the sixth nerves wound round the bulging posterior border of the tumor, especially that on the right side. The tumor proved to be a typical glioma.

OPERATIVE TREATMENT FOR RAPID CURE OF DACRYOCYSTITIS.

Guaila's (*Centralblatt für praktische Augenheilkunde*, January, 1892) operation is performed in the following manner: The patient sits on a chair with his head slightly bowed forward, and held in this position by an assistant; the sac is then incised from the outside, and if there is much bulging of the skin, a small oval piece is removed, together with the fistula, if one should be present. The blood does not get into the patient's throat, as happens when the ordinary recumbent posture is adopted. One then scrapes out the entire inside of the dilated tear sac, being especially careful to remove any diseased bone met with, and having mopped out the cavity very freely with a solution of sublimate of 1 in 5,000, a bone cannula (to be described below) is inserted and the wound stitched up. The cannula is certainly a novel feature of this operation; it is made by decalcifying with hydrochloric acid, 5 per cent., the bones composing the posterior limbs of large toads, divided into the proper lengths, and hardening and preserving them in a mixture of alcohol and sublimate. The knob-like end of the bone at the joint prevents the cannula slipping into the nose too far. This procedure has given excellent and apparently permanent results in the 314 cases the author has used it in.

REMARKS ON THE TREATMENT OF TRACHOMA BY THE EXPRESSION OF THE MORBID SUBSTANCE WITH A ROLLER FORCEPS, BASED ON A SERIES OF 114 CASES.

Dr. H. Knapp, (*Archives of Ophthalmology*, Vol. xxi, No. 1.) refers to the method for the ordinary treatment of trachoma as being unsatisfactory and tedious. He gives a wood-cut of his roller forceps and describes his method of using it.

Of the 114 cases treated there were 16 cases of follicular catarrh, 64 cases of follicular trachoma, 22 cases of diffuse trachoma, 10 of cicatricial trachoma, and 2 cases of horny summer granulations.

Of the 16 cases of follicular catarrh, fifteen were cured. Fifty-four of the cases of follicular trachoma were cured, and of eight no record was given, but a cure was believed to have occurred. Of the 22 cases of diffuse trachoma, seventeen was cured, three did not report after treatment, one had a relapse, one had an attack of acute conjunctivitis six months afterwards, but no return of the granulations. Knapp states in reference to his forceps: "The newer instruments have conical pivots which dip into corresponding depressions. Tiemann & Co., proposed also to make an instrument with longer limbs of the stirrup and a set screw to remove and cleanze the pivots and sockets. At my suggestion they made the branches a little longer somewhat elastic so that the roller can be removed and reinserted."

sules, though no symptoms of Addison's disease were present. This case shows the diagnostic importance of a væteriological and microscopic examination of empyematous matter.—*Prof. Frænkel, Berl. Klin. Wochensch.*

OBSTETRICS.

PERINEORRHAPHY DURING PREGNANCY.

Weil (*Prager med. Wochenschrift*, 1892, No. 11) reports an interesting case of laceration involving the sphincter and recto-vaginal septum, in which he operated in the fifth month of pregnancy, the patient being delivered at term without injury to the perineum. He regards the operation as justifiable during pregnancy when the patient is rapidly losing her strength from diarrhœa, so that abortion is imminent, and suffers severely from the loss of perineal support. The danger of infection during labor, by reason of the communication between the rectum and the vagina, is to be borne in mind. Care during the delivery of the head, with the performance of episiotomy, ought to prevent a second laceration.—*Amer. Jour. Med. Sci.*

TREATMENT OF ASPHYXIA IN NEWBORN CHILDREN.

W. E. Forest (*N. Y. Med. Rec.*, April 9th, 1892) objects to the Schultz method of artificial respiration in infants (supplement February 28th, 1891), that is too violent, and that it must lead to great chilling of the surface, which may be sufficient to determine the death of the child. He suggests the following method:—The child is laid for an instant on its face, with the head and thorax lower than the pelvis, and quick but gentle pressure is made on the back; this is to expel fluids which may have been drawn into the air passages. The child is then placed in the sitting posture in a pail containing warm water in sufficient quantity (about 6 or 8 inches) to rise a little above the level of the heart. The water should be as hot as can be borne comfortably by the operator's hand. The left hand grasps the wrists with the palms outwards, the right hand supports the back, the head resting between the thumb and fore-finger. The thorax is placed in the inspiratory posture by carrying the child's hand upwards until it is suspended by the arms, the buttocks just raised from the bottom of the pail. Forest contends that in severe cases, in which alone artificial respiration is really required, this will not be sufficient to cause air to enter the lungs since the air cells have never been distended, and cannot be distended merely by placing the chest in the inspiratory position; his method, he maintains, enlarges the thoracic diameters to their maximum, and should be combined with direct insufflation. When the arms are raised the head falls backwards, and in this position, he says, the œophagus is closed; the operator blows into the child's mouth while still holding it in this position, and so completes inspiration; expiration is effected by lowering the child's arms until the left hand of the operator rests against the front of the child's thorax; its body is then doubled forward, and gently compressed between the two hands of the operator. The main advantages claimed for the method are that it is gentle and effectual, but especially that it provides for maintaining the body-temperature, and so favors the re-establishment or maintenance of the circulation.—*Brit. Med. Jour.*

GYNECOLOGY.

REMARKS ON THE OPERATION OF EXCISION OF THE BREAST AND ITS AFTER-TREATMENT.

Gould (*Lancet*, London, 1892, vol. i., No. 8) speaks of certain special points concerning this operation. In the matter of the direction of the incision, the author states that two considerations only should guide the surgeon. The first is imperative and has to do with the complete removal of the nipple and skin over the tumor, when that is malignant. The second is to have the cicatrix parallel to the fibres of pectoralis major. In most cases both of these objects are best attained by the same incision—one enclosing an ellipse of skin parallel with the anterior fold of the axilla when the arm is at a right angle with the trunk. It is stated that it is sometimes convenient to prolong the incision into the axilla, but never necessary, as the axilla can be readily reached from any incision for amputation of the breast. The writer

has thoroughly cleaned out the axilla in two cases of scirrhus of the breast, through an elliptical incision over the gland, the long axis of which was vertical.

When the mamma is not the seat of malignant growth, it is recommended not to invade the axilla, and even in cases of sarcoma the axillary glands are not to be removed unless affected. In cases of carcinoma, however, the glands should be removed from the axilla, together with the mass of fat in which they are situated. The intercosto-humeral nerve should be preserved.

Bleeding vessels are caught with pressure-forceps as fast as they are cut. At the conclusion of the operation the forceps are carefully removed. Occasionally one or more arteries will require twisting. A ligature is never necessary. Sponges are used only to dry the wound and are never to be rubbed over its surfaces. The less they are used the better.

The wound is to be thoroughly flushed with bichloride solution 1:2000. A continuous suture of fine chromicized catgut is recommended, each loop being caught up—the buttonhole stitch. A drainage-tube is not to be employed. The dressing should be aseptic and it should secure accurate apposition of the wound-surfaces. The author uses four layers of boric lint to lay over the wound, the margins extending an inch beyond the wound in all directions, This is held in place by strips of plaster two inches wide. Over this, gauze or wool is applied, and held in place by a roller bandage carried around the trunk in an ascending figure-of-8. The arm is held to the side by means of an ordinary chamber-towel. The towel is folded lengthwise, and between the two folds the forearm and arm are placed, the hand being just within one end. The towel is then fixed in place by pins.

During the first twenty-four hours a firm pillow placed under the arm of the affected side may relieve the usually distressing backache. After the first day the patient may be raised to a sitting position by pillows or a bed-rest. The dressing may be removed on the seventh day, when the stitches may be carefully taken out. The wound is re-dressed by two layers of sublimate gauze, fixed with collodion, and over this a light boric lint dressing held with the roller bandage.—*Amer. Jour. Med. Sci.*

DEATH AFTER INTRAUTERINE INJECTION OF PERCHLORIDE OF IRON.

H. Pletzer (*Centralbl, f. Gynak.*, May 7th, 1892) publishes the following case which occurred in Bonn last winter. A woman, aged 32, was admitted on November 10th, 1891, for retroversion and chronic endometritis. In 1881, after contracting syphilis from her husband, she had a stroke of right hemiplegia, and the right extremities retained traces of paralysis when admitted. She had borne seven children, five macerated or premature; the retaining two died when about two weeks old. On November 11th, 1891, the curette was freely used and the uterine cavity was afterwards painted with tincture of iodine; a Hodge's pessary was also applied to relieve the anteflexion. On November 16th and 18th the uterus was washed out with a 2 per cent. solution of carbolic acid, and iodine once more applied. The period began on November 20th and lasted till the 26th. The uterus was then treated every two days as before. As uterine hæmorrhage set in, it was thought advisable to inject iron. About ½-drachm of the liquor ferri sesquichloratis (which is 10 per cent. weaker than the liq. ferri perchlor. fortior *B. P.*) was carefully injected into the uterus after previous syringing with the carbolic solution. The syringe had lateral holes, and free escape of the injection was ensured by means of a Bozemann catheter. Then the uterus was washed out once more with the carbolic solution and the patient put to bed. The injection of iron caused pain at the time. Fifteen minutes later colicky pains set in. Pletzer was called back and found the patient livid, breathing, stertorously, and complaining of severe hypogastric pain. In spite of all kind of treatment the patient grew worse and died two hours and a quarter after the beginning of the alarming symptoms. An old lesion was detected in the left thalamus opticus. Small clots were found between the trabeculæ in the right heart, and soft, non-adherent clots in the pulmonary veins. A large coagulum was discovered in the right internal iliac vein. There was a distinct breach of surface on the inner wall of the uterus, with strong evidence that through it the iron had entered the veins. Pletzer refers to Cederskjold's similar case, where the uterus was in a state of subinvolution.—*Brit. Med. Jour.*

PEDIATRICS.

INVASION OF THE SUBCUTANEOUS TISSUE BY THE DIPHTHERIA BACCILUS.

In three out of four cases of diphtheria Spronck (*Centralbl. f. allg. Pathol.*, January 1, 1892) found the characteristic bacillus in the œdematous tissues round about the tracheotomy wound. After laying open the trachea in rabbits, the author inoculated it with the bacillus of diphtheria, and then closed up the wound. Œdema often appeared round about the wound, and the same bacillus was found in it. Sometimes the œdema was very extensive as if a suitable soil had been provided. Rabbits showing this œdema died more rapidly than the others. The invasion of these tissues by the bacillus is signalized by this œdema. When the trachea is opened its movements favor the penetration of the micro-organisms, and subsequent cleansing may be insufficient to remove them. The toxalbumin produced by this bacillus is more readily absorbed from the subcutaneous tissue than from the surface of the mucous membrane. The author points to the probability that a patient's life may be thus endangered, and refers to cases where death ensues two or three days after tracheotomy, and no sufficient cause is found at the necropsy.—*Brit. Med. Jour.*

SYMPTOMS PRODUCED BY ADENOID VEGETATION IN YOUNG INFANTS.

Lubet-Barbon (*Mal. de l'Enf.*, Paris, 1891, Nov., 499.), reports that in a child of one month the symptoms presented were that it could not breathe while nursing, and while nursing was frequently seized with attacks of coughing. It did not gain in weight, breathed with mouth open and had a constant muco-purulent discharge from the nostrils. In another case, a child aged sixteen months, there were difficult respiration, mouth-breathing, dryness of the lips, the face of violet hue; the respiration was noisy, hoarse, frequent, such as to closely simulate the respiration in a case of croup. The child has never been able to take the breast nor nursing bottle, but had been fed from a glass. Cough was frequent and often caused vomiting. In another case there was considerable emphysema. Four cases are reported. In all the treatment consisted of removing the growth by means of forceps of a particular model. The operation was performed at several sittings. In all complete recovery or great improvement followed.

ANTIPYRIN IN DIPHTHERIA.

Vianna (*Sem. Méd.*, March 30th, 1892), has found that antipyrin has a marked bactericidal and toxinicidal action on the bacillus diphtheriæ. He finds, first, that addition of the drug to culture media, in the proportion of 2½ per cent., renders these unsuitable for the nutriment of the microbe; secondly, that when added in the same proportion to actively growing cultures it causes their death within forty-eight hours; thirdly, the toxines are also destroyed, for cultures treated as above, and also filtered cultures, to which antipyrine is added, prove much less virulent to guinea pigs than the original cultures, animals living five to eight, twelve, fifteen, twenty, and twenty-four days, as against three days for the control. Vianna, therefore, strongly recommends the use of antipyrin as a therapeutic agent in diphtheria.—*Brit. Med. Jour.*

HYGIENE.

DISPOSAL OF SEWAGE.

The disposal of sewage is a question which has been to the fore for a good many years in various countries, says *Engineering*, but which, perhaps, nowhere on the Continent has been dealt with in a more systematic manner than in Germany. In Berlin the drains from the houses receive both the rain water, and dirty water, the dirty water from the kitchen, etc., and the contents of the water closets, conduct them to a system of radial sewers, through which they, by a natural fall, proceed to a dozen various pumping stations within the area of the town. From these the sewage, through the medium of combined force and suction pumps, passes through pipes of three feet or still greater diameter to the land which the corporation of Berlin possesses, and where the sewage is used as a fertilizer. The sewage makes its

final exit through a system of conduits so arranged that before reaching them it has parted with all its manurial power to the soil through which it is made to pass. The sewage water thus filtered reaches the river through the natural fall of the conduits in a comparatively purified state. The sewage is an exceptionally good manure, and the yield of grass on those fields that receive it is something quite out of the common, so that it can be cut some six or seven times during one summer. This system also seems to answer well as far as the sanitary side of the question is concerned, but still there are a good many places which prefer the method by which the sewage is collected in large tanks, whereby it is possible to benefit larger areas by its fertilizing qualities. Frankford-on-the-Maine is another German town where the sewerage system is very perfect, but owing to the excessive cost of land in that locality the sewage is not, as in Berlin, used as manure in the first instance. The sewage is purified before being allowed to escape into the Maine, and the residue is pumped into receptacles from where the farmers fetch it. The town of Hanover is also about to adopt the sewerage system on a larger scale. In Augsburg and Heidelberg the barrel system is used, much more satisfactory in the latter than in the former town. In Heidelberg the corporation itself attends to the emptying of the barrels.—*Science.*

MICROBICIDE SUBSTANCES OF THE SERUM AND ORGANS OF WARM-BLOODED ANIMALS.

M. J. De Christmas (*Annales de l' Inst. Pasteur*, No. 8, 1891) contributes a paper on this subject. Recent experiments have brought a large amount of evidence against the notion that this microbicide power is in any relation to natural immunity. The experiments now described seem to show that it is after all a merely physical or physico-chemical phenomenon. As serum does not long retain its toxicity, the following special method has to be adapted for demonstrating its microbicide power: (1) A tube containing the serum is inoculated; (2) a drop of this mixture is withdrawn at once and used to inoculate a gelatine plate (control); (3) at varying intervals other plates are made from the same tube. Comparison of the numbers of colonies appearing in the plates will give them an idea of the bactericidal power of the serum. Possible sources of error in this method may be (*a*) an irregular distribution of the bacilli; (*b*) unequal size of the drops used to inoculate the plates. Christmas, working on the lines of Metschnikoff, shows also that abrupt changes in the density of the surrounding medium have an inhibitory effect on microbes, so that they may even be killed if inoculated from a more dense to a less dense medium. Taking an anthrax virus which has been grown for ten generations in serum, and introducing a drop of it into each of three tubes containing respectively *bouillon*, sterile distilled water, and boiled water, he made a series of plates from each in the manner above described. Counting the colonies, he found in every case that a very apparent microbicide action had taken place. Other experiments show that perhaps much of the microbicide power of fresh serum is due to the presence of dissolved carbonic acid, for, eliminating the error from difference of density, and using tubes of *bouillon* and serum through which a stream of CO_2 had been passed, the author demonstrated that plates made from these showed little or no development of colonies. In a further series of experiments he proves that normal serum of rabbits, dogs, and horses has of itself little microbicide power, at any rate towards the following: B. anthracis, B. typhosus, B. pyocyaneus, B. diphtheriæ, St. pyogenes aureus. Quite a different result is obtained with the albuminous substances separated from serum by alcohol, and dissolved in distilled water. This solution shows itself very slightly favorable to the growth of microbes. Heating or considerable dilution renders it more assimilable, but even then microbes will not develop well in it. The explanation offered is that microbes require, in order that they may assimilate albuminous bodies, the presence of traces of peptone, and this substance is absent from such solutions. Other more subtle influences may, however, also be at work. In the last part of the paper Christmas attempts to determine whether the albuminoid substances prepared from the organs of animals are similarly by themselves unfit for the nutrition of microbes. In these experiments he uses the organs (1) of normal rabbits, and (2) of rabbits rendered immune against anthrax by pre-

vious injection either of the products of anthrax grown in an albuminous medium, or of a sterilized aqueous extract of the organs of rabbits dead of anthrax. To prepare his albuminoid liquids he adopts the following process. The organs are finely minced, and allowed to stand for twenty-four hours under glycerine, which is then separated and treated with strong alcohol. An abundant precipitate is obtained, which is freed from glycerine by alcohol, dried, and dissolved in water, the last traces of alcohol being removed by a current of warm air. The resulting liquid is yellowish, alkaline, becoming turbid on boiling, and giving a white flocculent precipitate with alcohol. This solution, if obtained from a "receptive" animal, behaves towards bacilli just as the solution of albumins obtained from serum does. Addition of a trace of bouillon to this made it an excellent nutrient medium. If however, the solution were made from an animal rendered immune, the result was different. In this case the liquid would not serve as a nutrient medium, even when mixed with two-thirds of its volume of bouillon: in fact it possessed some antiseptic power. Christmas does not state whether it has the power of rendering animals immune when injected into them. He holds, however, that the substance is not the same as the vaccinating substance contained in the organs of animals dead of anthrax. As to what this liquid contains which is not present in a similar glycerine extract from normal rabbits—whether it be a "defensive proteid" or a ferment—the author gives no definite evidence.—*Brit. Med. Jour.*

VACCINATION LAW IN ITALY.

A new vaccination law went into effect in Italy with the beginning of the year, which requires that every child shall be vaccinated before it is six months old, and again at eight, or at any time whenever the sanitary authority deems it necessary to promote individual or public safety. Those who are not vaccinated and revaccinated according to the requirements of the law, are excluded from schools, factories, workshops, benevolent institutions, etc. Provision is also made for the cultivation and supply of both animal and human lymph.

MEDICAL CHEMISTRY.

PHYLLANTIN.

This is the name given by M. Ossow, a Russian chemist, to a bitter principle extracted from *Phyllanthus niuri*, an euphorbiacea from Java. The new principle has the formula C_{30} H_{37} O_8. It crystallizes in colorless needless which frequently form rosettes or fans. It is almost insoluble in water but dissolves freely in alcohol, ether, chloroform, benzene, benzol and glacial acetic ether. Its toxicity is the most notable thing about phyllantin. It is most deadly, but the exact limits of its toxicity have not yet been established.

TESTING DIABETIC URINE.

Every one familiar with the behavior of diabetic urine towards Fehling's solution is aware of the fact that in many cases the reagent causes a yellowish or greenish-yellow separation (it can hardly be called a precipitate), which refuses to settle for a long time, and sometimes does not settle at all. J. Seegen has recently proposed a method (*Wiener klin. Wochenschr.*, Nos. 6–8) by which this difficulty may be overcome. It is as follows:

Upon a filter in a funnel place some finely powdered animal charcoal (from blood) and pass through it 20 to 40 cc. of urine. Pour the filtrate back until it comes through colorless. Next wash the charcoal with distilled water. The original colorless filtrate and the washings are used for the determination of the sugar. When the original urine contained only about 0.1 to 0.05 per cent. of sugar, the reaction appears in the following manner. The original unfiltered urine decolorizes Fehling's solution and causes, at most, a dichroic, greenish-yellow turbidity. The decolorized, filtered urine, when treated with Fehling's solution and boiled, develops a yellowish turbidity, due to the formation of cuprous hydroxide. In the first wash water the same may still happen, but in the second and third a clean precipitate of red cuprous oxide is obtained, such as is formed in pure aqueous solution of sugar.

For *quantitative* purposes the method is applied as follows: About 50 cc. of the urine are poured into a filter half filled

with blood charcoal, and the filtrate poured back again until it passes entirely colorless. The charcoal is now washed with very small quantities of distilled water, the washings united with the filtrate, the liquid measured (it is best to bring it to the original volume of urine, filtered), and a portion then tested in the usual manner. The red cuprous oxide will now be found to separate in a normal manner. There is, however, a loss of sugar, since the charcoal retains some of the latter. Experiments have shown that this loss amounts to about 10 per cent.

NEWS AND MISCELLANY.

THE SCALPEL.

The Scalpel is the title of a new college magazine issued by the College of Physicians and Surgeons, of Chicago, Ill.

A BIOGRAPHY OF PROF. D. HAYS AGNEW.

At the request of Mrs. D. Hays Agnew, Dr. J. Howe Adams is preparing a biography of her late distinguished husband; in consequence, he is looking for data on this subject, and is desirous of obtaining from all of Dr. Agnew's former friends, colleagues, associates, students and acquaintances all such authentic data as relate in any way to his career or character. Dr. Agnew's acquaintance was so vast and his life was so actively spent among his friends, while his own modesty was so marked, that undoubtedly a great many incidents, anecdotes, characteristic stories, etc., etc., are unknown to his family. All material, however insignificant or small, will be welcomed, and credit will be given to all data which are used.

VACCINATION IN ITALY.

The *Sanitary Inspector* states that a new vaccination law went into effect in Italy with the beginning of this year, which requires that every child shall be vaccinated before it is six months old, and again at eight, or at any time whenever the sanitary authority deems it necessary to promote individual or public safety. Those who are not vaccinated and revaccinated according to the requirements of the law, are excluded from schools, factories, workshops, benevolent institutions, etc. Provision is also made for the cultivation of both animal and human lymph. This has a direct interest for people in this country in view of the large and constantly increasing Italian immigration.

A NEW, SAFE METHOD OF ADMINISTERING TOXIC MEDICAMENTS.

The increased knowledge resulting from research in the fields of botany, chemistry, physiology, pharmacy, and materia medica has created a demand on the part of the medical profession for the essential or active principles of drugs in preference to the more cumbersome, less definite pharmaceutical preparations which custom and authority have so long sanctioned.

Not a few alkaloidal principles of drugs have been isolated, and are now frequently prescribed. The conservative element of the profession have, however, in view of the toxicity of certain isolated medicinal principles, and the acknowledged variety of strength and activity of products of this character of different manufacture, been loath to employ them when indicated.

The doses sometimes being fractions of a thousandth or hundredth, it is not possible for the physician to always bear them in mind, and in prescribing he is often in doubt as to what constitutes the proper therapeutical dose, and what the dangerous toxic one.

Dr. E. Trouette, in a paper read before the Paris Academy of Medicine, and published in the *Revue de Thérapeutique*, entitled "Duodecimal Doses of Toxic Medicaments," proposes a method of obviating the difficulties hitherto preventing the general use of many valuable medicinal principles. The plan he proposes is a new method of dosology based on the rational division into twelve parts of the maximum dose which may be given to an adult in twenty-four hours.

The advantages claimed for this method are, first, accidental poisoning need no longer be feared. Second, dangerous medicaments may from the outset be given in efficient dose without the least risk.

One of our leading pharmaceutical firms has prepared diurnules and diurnal tablet triturates of a large number of toxic medicaments.

Clinical Lectures.

NUCLEAR OPHTHALMOPLEGIA IN THE COURSE OF TABES.

By DR. RENDU,
PARIS, FRANCE.

A CLINICAL LECTURE DELIVERED AT THE HÔPITAL NECKER.

Gentlemen:—I will to-day refer to you a patient who must have certainly attracted your attention on going through the wards, owing to his curious aspect and the characteristic appearance of his face. In fact, this man is suffering from a double ptosis; his eyes are tightly closed; he cannot open them, and so marked is the condition, that it has been necessary to apply a suitable bandage in order to keep elevated the upper eye-lids, without which appliance they inevitably fall. This paralysis stands by itself, so to speak, since the integrity of the other peri-orbital muscles is almost absolute; the movements of the eye-brows, those of the frontal, of the orbicularis palpebrarum, as well as of the other muscles of facial expression, are perfectly normal.

If you raise his eye-lids, you will immediately discover that on both sides, that is, on the right as well as on the left, the eye-ball is directed outwardly: in other words, there is a marked divergent strabismus. It is absolutely impossible for the patient to put the eye-ball in a normal position; there is a complete paralysis of the internal rectus. The upward and downward movements are likewise impossible to execute; nay, I commit an error in thus expressing myself, for the latter movement can still be made, its amplitude, however, being greatly diminished; and if you make a close examination you will see that it is accompanied with a certain amount of rotation of the eye-ball; this is effected by the intermediary action of the superior oblique. In one word, only the muscles supplied by the oculo-motor nerve are paralyzed, but (and this is an exceedingly important point) this nerve is not completely affected, since the size of the *pupil remains perfectly normal.* Contrary to what is seen in cases of ptosis, accompanied with external strabismus, there is no mydriasis. The iris is not paralyzed; it contracts perfectly to light, and you will observe that the pupillary orifice contracts or dilates according as an object is placed near or far from it. Add to this, finally, that the visual acuteness is normal, more so on the right side; on the left (where the ptosis is older) it seems that it is not entirely so.

If we are to investigate the cause of these symptoms, we will find that our patient has a most interesting history. His health had been good up to 1887; he had previously suffered, in 1865, from intermittent fever, and in 1868 contracted syphilis. He was afterwards, at Lyons, treated during 3 months for the perfectly characterized secondary symptoms of the constitutional disorder. After this he did not complain of any illness for a period of 20 years, and he thought that his syphilis had been entirely cured, which, I will repeat, was only treated during 3 months. The patient became afterwards subject to periodical cephalalgias and a slight trouble of the kidneys.

On the month of July, 1887, he went to South America, and there was obliged to make long rides on horseback. One day he was violently thrown from his horse, and when he returned to consciousness was told by his comrades that his left eye-ball was directed outwardly, and from that moment he continued to suffer from diplopia, which, as you see, had a sudden onset. At this time he was obliged to wear a bandage over the injured eye in

order to correct his diplopia, his vision being then confined to one eye.

There were, at the same time, other symptoms apparently foreign, so to speak, to the orbicular trouble: difficult micturition, at first slow and then a little painful; gastric derangement, and localized sweatings on the inferior extremities, accompanied with a pruriginous eruption over the plants of both feet.

Two months later, in February 1888, there appeared a progressive falling of the eye-lids, these being kept up only by means of the fingers. The patient could perceive also that the deviation of the eyes was on the increase; that the left eye-ball had already turned outwardly completely, and that the right one had commenced to exhibit a similar phenomenon. After this, he was not, strickly speaking, troubled with diplopia, but he had now lost binocular vision, and to-day the images perceived by him have an inclined form. Vision was only distinct in one eye, but at this time there had not appeared any ptosis of the right side.

This condition remained stationary during a period of 4 years, his general health continuing good, with the exception of occasional vertigos which he would experience especially when subjected to sudden drafts of air. He never suffered from dizziness nor from loss of consciousness. Fortunately for him, the ptosis of the left side completely destroyed the vision of one eye; by this he could see distinctly with the other eye; and he was thus enabled to continue at his trade which was that of a peddler. On the 29th of February, however, a change for the worst occurred. The patient, on attempting to bring down an object situated at a certain height, raised his head suddenly; and he was then attacked by vertigo, falling to the ground unconscious. He remained in this condition for 2 hours; when consciousness was regained he complained of severe pains all over the head, the back of the neck and the orbital region; the right eye-lid fell, and it became impossible for him to raise it now.

It was under these conditions that the patient sought our advice. Here is, then, an individual who has been attacked in succession (and every time in a rapid manner) by a double ptosis and paralysis of the movements of the eye-ball, movements which are under the influence of the oculo-motor nerve. It remains for us now to determine what is the lesion that has produced these various symptoms.

It is hardly possible to believe in that a cerebral, peduncular or pontine hæmorrhage has been the origin of such accidents. In a case of this nature we would observe upon our patient the existence of motor and sensory troubles; following the hæmorrhage or the congestion, there would appear a hemiplegia accompanying the ptosis, and afterwards a double hemiplegia if the lesion were extensive enough to affect both cerebral peduncles. The symptoms can be dated to 4 years ago; a hæmorrhage that old, capable of bringing about such disorders, would be followed, as is the rule, by a descending sclerosis characterized by contraction.

The hypothesis concerning a cerebral tumor affecting from the start the origin of one of the oculo-motor nerves, then that of the opposite side, deserves to be discussed with a great deal of care. This tumor might have lied upon two distinct points. Supposing it to have developed over the inter-peduncular region, on the level of the superior border of the pons; it could readily be understood how, provided it had acquired a sufficiently large size, such a tumor would press on the origin of the third pair. In such a case, however, we would have resulting motor phenomena, and partial tingling of the facial nerve, but nothing of the kind is observed in our patient.

Shall we admit, as in a case reported by Christ (*Deutsch. arch. f. Klin. Mediz.* B. XLVI, s. 497), the development of a tumor on the floor of the fourth ventricle, pressing on the nuclei of origin of the oculo-motor nerve, which are situated, as you know, not far from it? Under this hypothesis, the initial symptoms are identical with those we have observed in our patient; but their evolution is somewhat different. There may be produced, indeed, and quite rapidly, a progressive invasion of the motor centres of the face and neck, there coming on, in a few days, a labio-glosso-laryngeal paralysis, accompanied with ocular trouble, optic neuritis, etc.

Is it a syphilitic gumma with which we are dealing? Bearing in mind that our patient has, with a certainty, suffered from syphilis, this latter opinion may be entertained; but if we attempt to localize the

gumma, we come across certain difficulties, difficulties which we have pointed out in regard to tumors of the pons.

We can, nevertheless, solely by the analysis of the symptoms, come to the conclusion that we are dealing with a lesion affecting the floor of the fourth ventricle. Indeed, the dissociation of the present paralytic phenomena, the integrity of the pupil, contrasting with the ptosis and the paralysis of the ocular muscles supplied by the oculo-motor nerve, all this would incline us to admit the existence, not of a lesion of the nerve, but of *an alteration of its nuclei.*

You remember the beautiful researches of Hensen and Voelkers (*Archiv. f. Ophthalmol.* Bd. XXIV, S 1–26) regarding the origin of the third pair; you know that the nerve arises in isolated cells or in groups of cells, situated at the superior portion of the floor of the fourth ventricle, along the aqueduct of Sylvius. The fibres for the muscles have their origin in the nuclei alongside of the aqueduct; those for the iris, arise more externally, from the lateral portions of the floor. You will understand then, how lesions (the nature of which I have not yet established) of those groups of cells nearest the aqueduct of Sylvius, can produce motor phenomena of the eye-lids and of the eye-ball, without at all affecting the pupil. Is not this what is observed in our patient? The paralysis of the extrinsic muscles under control of the oculo-motor nerve, permits us to say that it is not due to a neuritis or to pressure upon the nerve; in this latter instance we would have a total paralysis. In the case under consideration, on the contrary, the dissociation of paralytic phenomena is the best proof that the lesion is of a centric origin, and that the lesion affects, although not all of them, the cells of origin of the oculo-motor fibres.

What is then the disorder capable of producing such symptoms? Are we dealing in the present instance with *superior acute poliencephalitis*, a good description of which has been furnished us by Wernicke (*Archive f. Psychiatrie*, 1889)? This is a disease as yet imperfectly known, characterized by a rapid destruction of the motor centres of the eye. Following the rapid invasion of an ophthalmoplegia there appear, in a very short time, symptoms of staggering, muscular rigidity and phychical disorders resembling those of a *delirium tremens.* This disease is ordinarily developed under the influence of alcoholism, in a rapid manner, and has a sudden termination in the course of from three to four weeks, or else death is preceded by symptoms of a labio-glosso-laryngeal paralysis. From an anatomical point of view, this disorder may be absolutely likened to an acute myelitis of the anterior horns. Now, in our case the development of the affection, which has been slow (it has lasted four years), and the absence of other medullary symptoms suffice for us to exclude the diagnosis just referred to.

Progressive atrophy of the medullary nuclei or centres may give rise to similar symptoms. This malady, whose process is the same as that of progressive muscular atrophy of the cord is quite rare; but I can cite two well marked examples of it. One of these cases is that reported by Bemhardt (*Berl. Klin. Woch.*, October, 1890): An individual, after an attack of nuclear ophthalmoplegia, exhibited symptoms of labio-glosso-laryngeal paralysis, and died suddenly; he did not show a single sign that would lead one to suspect the presence of tabes. The other case recorded by Wherry (Paragensia with ophthalmoplegia, *British Med. Jour.*, May, 1891) occurred in a man who after a sudden attack in which he did not suffer from loss of consciousness, complained of a bitter taste in the mouth, and then of diplopia, progressive ophthalmoplegia with deviation of the two eye-balls. A knowledge of the previous history of the case, led the author to admit the existence of a syphilitic lesion of the centres of the third pair, situated in the neighborhood of the aqueduct of Sylvius; such was corroborated by the fact that a complete cure was obtained after a course of an iodated treatment.

This observation presents a marked analogy with our case; yet I do not believe that we can accept a diagnosis of this kind. It is the presence of *tabes* to which we must attribute the eye-symptoms exhibited by our patient. Indeed, we have before us a tabetic patient, and I will show you that such is the case, by bringing to your consideration certain details concerning the pathological history of this individual, details to which I have not, purposely, directed your attention before. After the first symptoms of ocular paralysis, in 1888 and 1889, the patient suffered from sharp pains in the lower extremities,

which at first, were only occasional, but always of a lancinating character, peculiar to them; at the same time, the patient complained of a feeling of constriction over the thorax and in the head, and of sensory disturbances over the region of the trigeminal, such as numbness of the lips, loss of buccal and palatine sensibility. Micturition became difficult and laborious, notwithstanding that there was no stricture of the urethra. Finally, at the beginning of 1891, his walking became bad, and he assures us that his heels were particularly weak and had a tendency to draw towards one another.

After the last attack, which was accompanied with loss of consciousness, the symptoms became more pronounced. The patient could not stand erect, except when, by artificial means, he could keep one of his eyes open. The signs of Rombert and Westphal are now plain, and there are sensory disturbances, and especially marked, a spot of hypersthesia on the right thigh.

Here, therefore, the diagnosis is evident. We are dealing with a case of *tabes*, which manifested itself at first, by an ophthalmoplegia whose character, during four years, has been essentially progressive. I will, however, call your attention to the fact, that this tabes has exhibited a marked peculiarity, and the predominence of the medullary phenomena, the total absence of a special localization, of trophic or articular disturbances, distinguish it from other varieties of tabes with which we frequently meet.

The existence of oculo-motor paralysis in the course of locomotor ataxia, is not, moreover, absolutely rare. After the first works of Hutchinson, in 1879, a certain number of observations have been published. I will recall to your minds the quite recent cases reported by Pel (*Berl. Klin. Woch.*, 1890), Ziem (Ein fall von doppelscitiger ophtalmoplegie. *Centralbt. für. hervheilhunde*, 1887), Blanc (L'Ophtalmoplegie nucleaire, *Archiv. general. de med.*, 1887), and Dejerine who last year exhibited three patients whose condition was identical to the one that has been the object of this lesson. Ophthalmoplegia does not always present the same characters; it may be complete, the iris becoming implicated; the muscles of the eye-ball may be affected, while the elevator of the lid remains intact. From a clinical point of view, it is important to make a distinction between two great groups of ophthalmoplegia which affects all the extrinsic muscles of the eye-ball, and internal ophthalmoplegia in which only the iris becomes implicated. The onset of the disorders is generally sudden, that is, that of the paralysis the appearance of which indicates a permanent trouble, as well as that of simple functional disturbances that generally get well in a few weeks (Wherry). We must not forget, however, that relapses in these latter instances are not rare. We frequently meet with tabetic patients who show signs of ophthalmoplegia at more or less prolonged intervals.

How can we explain this phenomenon? It seems that an identical explanation cannot be given in every case. If, as is often the case, the ophthalmoplegia is due to centric lesion affecting primarily the nuclear origin of the oculo-motor nerves, completely destroying the nerve cells, it may also result from a primary alteration of the nerve trunks, from a neuritis of the oculo-motor nerves. This seems to me the most probable explanation that we can offer in cases of curable ophthalmoplegia. Neuritis of this nature comes on, most frequently, after an attack of an infectious disease during which, as you know, the poison has a marked tendency to localize itself upon the nervous system. In one of my last lectures I had occasion to show you a case of double neuritis as a sequela of influenza, and I then called your attention to the relative benignity of such neuritis, corroborated by the fact that in the case, a woman, sight was completely recovered soon afterwards.

In tabes, as I have said, slight cures of cases of ophthalmoplegia have been observed (Pel). Is this a sufficient reason to completely exclude, in such instances, a lesion of the centres, and to attribute the symptoms noticed to a neuritis? I, myself, do not believe in such a hypothesis, and it seems to me that up to the present time, it lacks evidence.

Dejerine believes that in order to establish a diagnosis between the centric and the peripheral origin of the symptoms observed, the fact of curability should, above all, be taken into consideration. Such an opinion, however, is absolutely free from criticism. Again, nothing will hinder us from admitting that a cell alteration, sufficiently marked to produce paralysis, is not susceptible of cure (a

complete cure), as in the case of a similar lesion of the nerve trunks. Finally, the dissociation of the paralytic phenomena is, to my mind, a capital proof in favor of their centric or nuclear origin.

What produces this alteration in the cells? It is more than probable that the symptoms are due to an acute congestion analogous to that which causes the lancinating pains; this hypothesis is in accord with the other inflammatory phenomena which accompany the ophthalmoplegia of tabetic patients: cephalagia, vertigo, pain in the back of the neck, and in the eye; it explains, in one word, the ordinarily sudden onset of the symptoms. This congestion, if persistent or repeated may, later, give rise to the progressive development of an ependymal sclerosis, comparable to that of the posterior spinal nerves, which may destroy the motor centres. These inflammatory outbreaks, occuring in the course of tabes, resemble very much those which you have seen come on in the course of general paralysis which has moreover, many other analogies with tabes; besides, it is not absolutely exceptional to see tabetic patients exhibiting cerebral disorders, such as difficulty of speech, vertigo, loss of consciousness, symptoms all which are similar to those occurring in general paralytics. We have at present, in one of our wards, a beautiful example of a similar association of symptoms which cannot be explained, I think except by the existence of a congestion of the brain.

On the other hand also, these circulatory disturbances of tabes may be traced to a vascular change, thus, Berger (*Bull. mens. Soc. Biolog.*, March, 1889) has reported a tabetic case in which he found the existence of an obliterating endoarteritis of the medullary vessels, which explained the symptoms observed. Finally, it is through the vascular alterations produced, that syphilis became the genesis of a large number of cases of locomotor ataxia.

In the present case the prognosis of ophthalmoplegia, in seems to me, is exceedingly serious; the symptoms are of too long standing to hope that they will retrocede. I believe that in our patient the paralysis will be permanent; in him the condition is incurable. On the contrary, it does not seem to me that the intregity of the sight is so seriously threatened. It is true that atrophy of the optic nerve comes on soon in the parataxic period of tabes or in the slow ataxias, but almost never does it coincide with the appearance of the ophthalmoplegia.

The greatest gravity of the prognosis is the danger of the medullary symptoms. If you admit that the phenomena observed in our patient are of a centric origin, and if, on the other hand, you will not forget that the oculo-motor nuclei are the neighbors of the circulatory and respiratory centres, you can readily understand how a more or less pronounced congestive process may bring about the production of serious symptoms, and even sudden death, as I have had the opportunity to observe in one case. Our patient has some difficulty of deglutition, which seems to show that the circulatory disturbances are not limited to the motor centres of the eye, but that they have a tendency to spread over the inferior portion of the fourth ventricle. The occurrence of such a development ought not to surprise us in the ordinarily rapid march of a medullary atavia.

I think that we are authorized in this case to give syphilis the preference, regarding the ætiology of the symptoms present; the onset of these, to a certain point, furnishes us the proof of our assertion. Indeed, the researches of Fournier has shown that 43 per cent. of tabetic cases occurring in syphilitic patients, begin at the brain, and the author concludes by saying that the cerebro-medullary form of tabes is observed especiallly in those syphilitic subjects in whose personal or hereditary previous history, moreover, it has not been possible to find a sufficient reason to explain that especial localization.

In spite of the probable syphilitic origin of this tabetic case, I do not believe that the specific treatment can produce an amelioration of the symptoms. Again, it is unfortunately the rule, in the majority of tabetic cases in which syphilis has been recognized as the cause, to find that the specific treatment is nearly always useless. Nevertheless, as this is the only rational medication to employ in such instances, I will not deprive our patient of it. I will, therefore, place him for a time under an active antisyphilitic treatment, such as mercurial inunctions and iodide of potassium internally in doses of from four to six grammes daily. I will also order revulsion and sulphur baths; but I will not

apply to the temples or the eye-lids, continuous or interrupted currents, because I believe that in cases of this nature electricity does more harm than good.—Translated from *Le Bulletin Medical*, No. 22, 1892.

PROGRESSIVE MUSCULAR ATROPHY; HEADACHE FROM EYE-STRAIN; HYSTERICAL VOMITING.

By C. L. DANA, M. D.,

PROFESSOR OF NERVOUS DISEASES IN THE N. Y. POST-GRADUATE MEDICAL SCHOOL.

Gentlemen:—You have already seen this patient once before so that it is not necessary for me to go into details of his case. From the general aspect of the right forearm you will see that he has progressive muscular atrophy. He is a boiler-maker by occupation. When I presented him to you before, I told you that the affection had come on very slowly; that there had been first a loss of grip, then atrophy, fibrillary contractions and vaso-motor disturbance, such as sweating. Progressive muscular atrophy of this kind is due to a degenerative process in the anterior horns of the spinal cord; it was formerly called, an *inflammation* but it is a progressive necrotic process, and not an inflammation. The plan of treatment which has been adopted, consists in injections of gr. $\frac{1}{25}$. of nitrate of strychnia daily, and it is my usual practice to give it alternately in the affected part, and in the back of the neck. It is given hypodermically, because experience has shown that in a certain proportion of the cases, the muscular atrophy is arrested by this treatment, and it seems reasonable to suppose that when a drug is administered subcutaneously, it "rushes" upon the nervous centres, so to speak, and exerts a more powerful effect upon them, than when it is slowly absorbed from the stomach into the circulatory system, and so gradually reaches the nervous centres. I frequently also prescribe phosphorus and arsenic, as in the following formula:

℞ Potassii arsenit.....gr. j.
Thomson's solution of phosphorus....oz. iv.
Misce. Sig.—One teaspoonful, gradually increased to a tablespoonful, t. i. d.

In addition to this, these patients should have the best of food, and an abundance of fresh air, and a moderate amount of electricity and massage. In progressive muscular atrophy, there is a temptation to yield to the solicitations of the patient, and do too much. You should pick out each muscle and electrify it with the faradic current, not more than six times at each seance, and massage should be carried out in the same careful way. Three times a week is usually sufficient, and I frequently alternate the electricity and massage.

The other day I saw a most pitiful case—a man who had been brought to this city from a western town. He had enjoyed excellent health up to four years ago, but at this time, his feet began to get weak, he noticed a steady wasting away of his muscles. About one year after this, the left leg began to be affected in the same way; first, the toe dropped, then the foot turned outward a little, then the calf began to waste, and after about a year and a half, he was unable to walk at all, and his two lower limbs were pefectly helpless. He then found that when sitting in a chair, if he leaned forward, he could not resume his former position, and if he leaned over backward, he would fall; in other words, the muscles of the abdomen, and the erector spinæ muscles had become weakened. The arms were the next to become affected. He had during this time, consulted a number of physicians, and some of them had been much puzzled over his case, but all expressed the opinion that his condition was incurable. As a last resort, he came to this city, a physical wreck, although his mind still remained keen. After careful electrical and other examinations, I made a positive diagnosis of chronic poliomyelitis of a progressive character, a condition which bears a very close relation to progressive muscular atrophy. The anterior horn cells in this man's spinal cord four years ago began to degenerate; first the right leg, then the left leg groups, then those of the back became affected, until now there is scarcely any gray matter in the anterior horns. So great have been the ravages of the disease, that now the prognosis is almost hopeless. I expect that there will next be some difficulty in speech or deglutition, or that he will have a respiratory paralysis from involvement of the phrenic nerve.

We are taught that progressive muscular atrophy is a hopelessly progressive disease, but this is not true, for there are certain types in which the progress of the

disease can be staid. One observer reports a series of eleven cases in which the atrophy was checked in eighty per cent. of the cases of hypodermic injections of nitrate of strychnia. I believe in the utility of these injections, and I think in addition to this, the "rest cure" should be prescribed, and the patient given stimulants and abundance of good food, particularly fatty food.

HEADACHE FROM EYE-STRAIN.

This next patient is a plumber by occupation, and he comes to us with the familiar story of a pain in the head. He does not smoke, drink, or chew, so that we cannot attribute his trouble to such vices. These pains first began about three months ago, and they are usually located in the temples, although sometimes they are felt in the top of the head. They do not always begin at the same time in the day, and they are attended by a certain degree of mental confusion, but without nausea or vomiting, or dizziness. He is not anæmic or dyspeptic. So far as I had time to test his vision, it is fairly good. The case evidently is one well calculated to bring out important points in connection with the general ætiology of headaches. I think you will all admit that we can exclude most of the *reflex* headaches. The *vascular* headaches are those which we find in anæmia and chlorosis, and uræmia, or associated with what are known as the rheumatic, gouty, and diabetic diatheses; in other words, where the headache is the result of a toxic condition of the blood from the development of a poison within the system. There is no such condition present in this patient; nor is there any history of hysteria or neurasthenia, so that we can exclude those headaches which are classified as *neurotic*. The *toxic* headaches are those due to alcohol, nicotine, lead, syphilis, etc. He has no symptoms of lead poisoning, and the history is distinctly negative as regards the others. Finally, there is the headache of the organic disease —tumor, catarrh and diseases of the frontal sinuses, etc. I think we can exclude all these in his case. I have gone over these causes of headaches systematically in order to show you how helpful to diagnosis such a method of examination becomes, if put into practice habitually.

Let us consider more in detail for a moment the condition known as *migraine*. Migraine usually begins before the age of nineteen and twenty years, and is most commonly one-sided, and accompanied by some nausea, and paroxysms ordinarily occuring with more regularity than they do in this man. I consider that his headache is due to eye-strain, and I propose to have his eyes carefully examined by our colleague in ophthalmology. If the trouble with his eyes proves to be slight, I would not prescribe eyeglasses for him until I had first determined what could be done by toning up the system in general, for, many people with marked errors of refraction will go through life without much annoyance until they become run down in health or neurasthenic, when they will become aware of the existence of this defect in their vision, and in such cases, measures directed to the general condition, will cause a rapid improvement in the local trouble. A rough and ready method which is often of service in the office for ascertaining the existence of insufficiency of the internal recti consists in covering up one eye of the patient, and directing him to look fixedly at a pencil which you hold before the eyes and gradually approach to the face. When it is brought near to the eyes, you quickly uncover the eye, and if there be such an insufficiency, you will notice that both eyes do not converge upon the pencil, but look in different directions. This you see is the condition in the patient before us.

HYSTERICAL VOMITING.

This young lady has been suffering for three years from a very distressing malady. She is fifteen years old, and has been in good health before this illness began. About three years ago, she began to vomit almost all food immediately after it was taken. This was not accompanied by nausea or any particular distress. She has been subjected to various kinds of treatment, up to the present time without benefit. She tells me however that when she is away on a visit, or goes to a new place to work, she is not troubled with it for a while. These facts are very instructive as they throw much light on the cause of her trouble. She has apparently dyspepsia; the tongue is clean and moist, the bowels move regularly, and contain digested fæces, notwithstanding that she tells us that she throws up "all her food." It is evident that she does not throw up as

brain, stomach, or kidneys, and we are therefore driven to the opinion, which is borne out by the history, that the case is one of hysterical vomiting, and I am glad to be able to show her to you as it is a very typical example of this condition. I always like to test such cases for the subjective evidences of hysteria. In the severer forms of hysteria you will always find the "stigmata" of this condition. They consists of disturbances of the special senses, such as concentric limitation of the visual field, loss of color sense, limitation of the range of hearing, divergence of the sense of smell and taste, anæsthesias of the hands and legs. These anæsthesias were formerly thought to be always distributed on one side of the body alone, but this is exceptional. They are usually distributed over the hand and forearm, and over the foot and leg very much like a glove or stocking. When present, these stigmata are extremely valuable as showing the nature of the disease. This young lady, strange to say, did not have these when I first examined her, but she did have what we often find in American women, a general sensitiveness of the whole body, and an abnormal acuteness of all her special senses. I presume her stomach shares in this hypersensitiveness. We conclude, then, that the general diagnosis of this case is hysteria, and the special diagnosis, is hysterical vomiting, or a neurosis of the gastric nerve.

I cannot give you the exact physiological mechanism of this process, because I have not watched this person in one of her attacks. In some of these cases, the food is not all swallowed, but some is retained in the lower portion of the œsophagus, in a sort of second stomach, and is afterwards regurgitated, instead of being really vomited. This is an old and strongly rooted habit in this lady, and some heroic therapeutic measure will be required. The surest way would be to take her away from home and put her in an institution where she would be under strict supervision. Then, the use of cold baths and the administration internally of two or three grains of the valerianate of zinc, three times a day, would be indicated. It might even be necessary to have her stomach washed out. I think she would also be amenable to hypnotism, but I have not sufficiently tested her as yet as to this point. A very simple way of testing patients re-

much food as she would have us believe. We find no evidence of any disease of the garding their susceptibility to hypnotism is to place a thimble, such as is used in banjo playing upon the patient's finger with a mysterious air, and then direct her to watch the finger intently for about fifteen minutes to see what will happen. If the patient perceives a numbness in the finger, the test indicates that she is a good subject for hypnotism, but if on the contrary, she laughs at the idea of watching the thimble, and evinces much skepticism as to the probable result of the test, it will be well for you to abandon all thought of trying to treat her by this method.

PYREXIA IN URÆMIA.

Richardiére and Thèrèse (*Rev. de Mèd.*, December 10, 1891) say that pyrexia not only does not exclude uræmia, but may permit its recognition and even prevention. It does not depend on the symptom-complex nor on the nature of the renal lesion. In the uræmia of acute Bright's disease one is tempted to explain the temperature by the local inflammation; yet it is uncommon to see uncomplicated acute nephritis with any marked rise of temperature. Uræmia, whether in the form of convulsions, coma, or delirium, may be attended with pyrexia, and therefore the temperature in uræmic eclampsia is not to be attributed to the increased muscular movements. No cases are recorded of uræmia with pyrexia when the symptoms have been referrable to the alimentary canal or respiratory system. The course of the temperature is in relation with the intoxication. It rises with the premonitory symptoms, attains its maximum with the attack, and falls when the uræmia symptoms improve or disappear. The pyrexia has no special prognostic significance. Once the temperature becomes normal the attack may be considered over. The cause of the pyrexia lies in the uræmia as it is seen apart from visceral complications. Cerebral œdema was noted in some fatal cases. Two substances have been found in the urine, one of which, when injected into animals, produces a rise of temperature (Binet), the other a fall of temperature (Bouchard), and the authors think that in the auto-intoxication of uræmia there is or is not fever, according as the one or other predominates.—*Brit. Med. Jour.*

THE TREATMENT OF ACUTE ARTICULAR RHEUMATISM: A CLINICAL AND STATISTICAL STUDY OF EIGHTY-FOUR CASES WITH A CONFIRMATORY PLEA FOR THE SALICYL-ALKALINE TREATMENT.*

By D. H. WILLIAMS, M. D.,

EX-HOUSE PHYSICIAN, BELLEVUE HOSPITAL; PROFESSOR OF THERAPEUTICS AND PHYSICAL DIAGNOSIS, AND PROFESSOR OF MICROSCOPY, TENNESSEE MEDICAL COLLEGE, KNOXVILLE, TENN; MEMBER TENNESSEE STATE MEDICAL ASSOCIATION, ETC.

In a mental debate as to the contents of this paper with special reference to the therapeutics of acute articular rheumatism, the author was forcibly reminded of a truism expressed even so long ago as 1837 by an author in his introduction to a book described is an October number of the *Botanico-Medical-Recorder*, in which introduction he said: "The old school materia medica will be critically examined, it will be shown that the remedial agents are not to be depended upon, and that no two authors who have written upon the subject precisely agree as to the effects which many of them produce. The discrepancies of medical authors from Hippocrates down to the present time will be accurately detailed."

In the light of the advancement of the nineteenth century, and that of all preceding years, an impartial critic must even now write in a similar strain.

It is easier now than then to characterize discrepancies, but it is often as difficult to establish our own preferments by well-conceived and scientific conclusions.

Pathological anatomy through macroscopical and microscopical methods has demonstrated the various nucleolar and protoplasmic changes, and denominated the many orders of schizomycetes to the almost satisfaction of investigators. For that we honor it, as well as for the new therapeutic means which these investigations have suggested, resulting in the cure of diseases hitherto considered incurable; but even pathological anatomy, while it has not nearly reached its limit, has as yet failed to define satisfactorily some of the commonest of maladies, notably acute articular rheumatism.

Medical scientists are daily growing more averse to the consideration of any drug or drugs in a given disease, the therapeutic action of which in that particular disease cannot be thoroughly explained, and yet who can deny that in the treatment of syphilis in its several stages, we have specifics in mercury and the iodides.

In the absence of light as to the ætiological factor producing syphilis, if scientific, it would not be humane to refuse to use those drugs which are known clinically to have great value.

That acute articular rheumatism is due to the entrance of some morbific principle into the blood, is very generally conceded, but investigations in the direction of its nature have hitherto been futile; the pathological changes produced by that agent are well understood, but throw little light upon its prime factor.

Of the many theories advocated, the one attributing it to a specific organism seems very plausible, although as yet the agent has not been demonstrated.

That it is due to the retention in the blood of some excreted or changed substance, and that substance uric acid or some modification of it seems highly probable from many points in the natural history of the disease; but whatever the agent, the above two theories can either of them be strengthened by clinical testimony of the good effects of the preparations of salicylic acid—known enemies to many forms of bacteria—and of the neutralizing alkalies.

One of the most difficult features in the clinical history of the disease to overcome, in the consideration of treatment, is the tendency of the disease to involve the heart, the serous and synovial membranes; but the most peculiar of all, in the matter of its relations to the blood, is the fact that it produces its ravages through the medium of arterial and capillary blood, almost totally ignoring the nervous system.

Why an agent so very effective in the production of organic valvular lesions should involve one side of the heart to the almost absolute exclusion of the other is a

* Read before the Tenn. State Med. Association, April 14, '92.

puzzling query, and one which must be satisfactorily answered before the true pathological character of the disease can be determined.

Can it be that in passing from the right side of the heart through the pulmonary circulation to the left side, this so-called morbific principle is increased in virulency; or is it probable that the arterial blood in passing through the systemic circulation is filtered, so to speak, of most if not all of this foreign virus; or after all is it of such a nature that it is destroyed or held in abeyance by the CO_2 of the venous blood, to be removed or set at liberty again by the oxygen of the air?

These are interesting and vital questions and must be answered before any logical deductions can be drawn relative to its true nature; answered before any treatment can be declared divested of empiricism, for as shall be shown later on in this article, of the 84 cases considered not one of them developed a lesion referred to the right heart.

Such lesions have been reported, but they must be exceedingly rare, and to require worthy notice must be proven to have developed under observation.

The writer does not deny the possibility. These few introductory remarks have been made by way of provoking discussion in order to arrive at some definite explanation of the good effects derived from the treatment of acute articular rheumatism, by the salicyl-alkaline remedies, and not with an attempt to introduce all of the many theories offered to explain its pathological character, for to do the latter would involve much time and prove of no practical value.

It may be added here, however, that while the theory of its uric acid cause seems to the author's mind to meet a number of demands than any other. He is not prepared to adopt it since experiments which he has made, and is now engaged in making, as the examination of the blood in health and disease, and the examination of serum drawn through the medium of an epispastic, etc., do not warrant him as yet in forming any conclusions; furthermore, such a discussion can scarcely come within the limits of this paper.

The conclusions which he has drawn from a study of the cases are based upon clinical evidences only.

Pari passu with the speculation as to the origin of acute articular rheumatism, has gone one after the other, rising and falling with popular favor and dissent, a host of drugs and remedial measures.

Mention of most of them he shall sedulously avoid, nor shall he discuss the merits of that treatment which sought at one time to prove that acute articular rheumatism is a limited disease demanding only palliative treatment, and little of that; one-half of the proposition is admitted and believed, but to one who has seen a helpless individual suffering torture equal almost to the the darkest days of the Inquisition, within the short space of a few hours relieved, if not entirely freed from pain by the judicious use of the salicylates and the alkalies as the basis of treatment, palliative treatment, only, seems short of criminal, nor will the free use of anodynes alone absolve the conscience.

The object of this paper being to bring into special prominence the treatment mentioned above, from a clinical standpoint, no attempt will be made to introduce any other routine other than the mention of certain drugs and methods which act as adjuvants.

The author does not see proper to make any such distinction as dividing cases into plethoric and anæmic, believing that all cases, provided they present themselves during the acute inflammatory stage, should be similarly treated, each case best suggesting subsequent remedies; neither does he think it necessary to divide them into acute, subacute and chronic since in the first place the present subject deals mainly with the former, and again his convictions lead me to believe that the joint inflammation is not a fair index of the ravages being produced by the circulating poison upon other tissue.

Granting a case presents itself with acute articular rheumatism for the first time, what should be done with it?

Occurring as it usually does in young adults, consider carefully the patient's habits, his manner of life, his occupation, his attention to sexual and general hygiene, etc., all of these things aiding far in subsequent treatment, and in advice towards warding off succeeding attacks.

In most cases it is advisable to give a cathartic as early as possible, the bowels usually being constipated.

An excellent combination is calomel gr. ¼, triturated with potassic-bicarb. grs. V, given every hour for eight doses, to be followed one hour after the last dose by one half ounce of rochelle salts, the latter repeated if necessary.

The above combination is useful for the following reasons: (a) Calomel in such doses is not only mildly cathartic but somewhat diaphoretic, and decidedly diuretic—each action in itself serviceable.

(b) The potass. bicarb., according to well recognized ideas, promotes the effect of the calomel, and additionally acts to aid in reducing the hyper-acidity of the fluids of the body.

The rochelle salts for obvious reasons, is decidedly indicated and should, in the writer's judgment, be used rather freely during the subsequent course of the disease.

So much for the preliminary treatment, if it can be called such; but even before the above has been carried out entirely, not interfering in any way with it, the administration of the alkalies and salicylates should be initiated.

Of the alkalies perhaps as good a one as any is the ordinary sodii. bicarb., given in sixty grain doses every four hours and repeated during the night if urgency demands it.

As to the choice of the salicylates there is much difference of opinion, unequivocally the writer prefers the sodii-salicylat. for several reasons: It is very soluble in water, is easily administered, is not so irritating as some others, and if it is true, as it is supposed, that the acid is itself converted into a basic salt and that salt sodii-salicylat., then rational therapeutics would call for the use of the latter.

Salicylic acid is preferred by some, the objection to it is its slight degree of solubility in water, unless in combination with a neutral salt, the borate of sodium adding to its solubility. An additional objection is the gastric irritation produced in some cases. It is not absorbed so readily as sodii-salicylat.

Salicin is perhaps less easily absorbed than either of the above, as observed by tests of the urine, saliva, etc. Clinically it is not nearly so reliable. The same may be said of salol.

In the treatment of the cases included in this study, several of them were put upon salicin and salol (as their histories will show) for the first three or four days, and their temperature noted.

Slight influence on either temperature or pain was observed. The cases were then put upon sodii salicylat., and marked changes noted.

This alone would not be conclusive evidence, since one might say that the disease had already run its course, had not many tests of the sodii-salicylat. from the beginning of the disease proved clearly that they were not mere coincidences.

The very fact mentioned here is also conclusive toward proving that the good effect of the combined treatment is not due to the alkali alone, as some have attempted to prove; if it were so then salicin plus an alkali would be, *caeteris paribus*, as effective as sodii salicylat. plus an alkali.

Many of the failures with the salicylates have been occasioned possibly—provided the cases were properly selected—by the injudicious use of the drug, in some cases giving too much, in others not sufficient. Few cases require more than 10 grains every two hours, and few require less. It has been the rule of the writer to give 10 grains, repeated every two hours during the night as well as during the day, as long as the acute stage lasts; and in a hospital like Bellevue Hospital, where the greater number of these cases were treated, the orders were very rigidly carried out.

In some cases it is advisable not to administer the night doses, but in many for the first three or four days it is safer, and by safer is meant in order to prevent or assist in controlling cardiac complications, for as shall be shown later on of thirty-six cases seen on an average of 6.02 days after the onset of the attack, only one developed any cardiac complication during treatment, ond that one developed pericarditis within ten hours after treatment was begun. Possibly the pericardial inflammation had existed even several hours before it was recognized.

This gives practically a perfect result, showing that before a certain date during the progress of the disease, in these cases an average of 6.02 days, if the patient can be saturated with the remedies, the danger of cardiac complications is much lessened.

The percentage of such complications as generally reported under a mixed treatment, is variously estimated, in endocar-

dial inflammations it is to put at from ½ of 1 per cent.—9 per cent.; in pericardial, it is placed at about 15 per cent. These figures, however, the writer believes do not represent the true number of cardiac complications, for every apparent murmur heard over the heart does not necessarily imply endocarditis, and on the other hand murmurs often exist indicating actual endocarditis, but are not recognized.

Perhaps some of the murmurs reported to have been heard over the right heart could have been shown to have other than a direct connection with the inflammatory process.

At times it may be found necessary to give fifteen grains of the sodii salicylate every two hours instead of ten.

One of the cases reported, a young girl of ten years, took fifteen grains every two hours for eight days, the treatment being repeated at night as well as during the day; at no time did she complain of gastric irritation, nor did she suffer from any disturbance of cerebration such a case, however, is very exceptional.

To *prevent* the *unpleasant effects of sodii sal.* upon the central nervous system, potass. bromide, in about ten grain doses, may be found serviceable.

Another important part of the treatment is to *promote diaphoresis* and the use of hot pack, or of a warm bath night and morning, provided the patient can submit to the moving, will be found very beneficial.

The bath is best used as the acute symptoms are subsiding but not at all if serious cardiac complications exist, unless the steam bath be employed, as 'tis advisable not to move the patient if avoidable. Heat thus used is very grateful and diminishes any existing pruritus; in some way it modifies the tendency to skin eruptions, which exists in a small per-centage of cases.

Dilute nitro-muriatic acid added to the bath affords comfort.

To *control the pain* constitutionally ℥ii of the U. S., sol. morph. sulph. internally, or Mvj or vij of Majendie's solution hypodermatically should be administered in all cases where much suffering exists.

Locally over the inflamed joints a lotion containing ammonium chloride acts excellently, afterwards wrapping the parts in flannel.

Heat or cold as seems most grateful might be used. Gentle massage often affords great relief.

For *diet* milk only, and continued for several days after the acute symptoms have subsided. The treatment of complications is not called for here.

During convalescence tonics are indicated, and the tr. ferri chlor. is one of the best for reasons connected with its physiological action.

If for any reason the sodii salicylate can not be borne, then the other salicyl-derivatives should be tried.

The oil of gaultheria containing about 90 per cent. of methyl salicylate may be found serviceable. Very few stomachs, however, will refuse the above treatment if the drugs are fresh and judiciously employed.

To meet any extraordinary indications the ingenuity of the attendant will offer suggestions.

The author does not and can not claim any originality for the principles laid down, and these remarks but preface a summary of cases treated on a basis fortunately widely recognized.

Again, he does not claim to have treated every case strictly on these principles, as some cases showing a tendency to chronicity were given potass. iodid., tr. guaiaci. ammonia, etc., with benefit. Cases combining that variety of phenomena and classified as rheumatic gout were given special treatment additionally, and where apparently they did not belong to the present summary were left out altogether.

The conclusions deduced were drawn from bedside observations, and after repeated examinations.

Following is the summary, the author refraining from reading each individual case.

Age.—Average age of all cases considered,					29.88	
Average age of all cases first attacked,					28.50	
Oldest first attacked was in a female,					65	years.
Youngest " " " "					9	"
Next youngest first attack (two cases),					15	"
Between the age of	15	and including	20,		16	cases.
" "	20	"	30,		39	"
" "	30	"	40,		18	"
" "	40	"	50,		7	"
" "	50	"	60,		2	"
" "	60	"	65,		2	"
Between the ages of	15	and including	25,		33	"
" "	25	"	35,		31	"
" "	35	"	45,		11	"
" "	45	"	55,		6	"
" "	55	"	65,		3	"

Least number for any decade, between

55 and 65, 3 cases. The first ten years of life not considered, as cases under fifteen years of age did not come under the writer's notice in hospital practice.

Greatest number for any decade, between 20 and 30, 39 cases.

Next greatest number for any decade, between 15 and 25, 33 cases.

Next greatest number for any decade, between 25 and 35, 31 cases.

The number between 15 and 35, 64 or 76.19 per cent. of all cases. The number before 30 years, 54 or 64.28 per cent. of all cases. The number before 40 years, 73 or 86.90 per cent. of all cases.

SEX.—Number of females considered, . . . 20
Number of males considered, . . . 64

COLOR.—Number of whites considered, . . 83
Number of negroes considered, . . 1

RACE.—

Average number days of duration after treatment in first attack . . . . . 16.40. (53 ")
Total number days to dismissal of case, in first attack . . . . . 22.79.

COMPLICATIONS.

Number of cases in which old cardiac complications existed . . . . . 17. 20.15 per cent.
Number of cases in which recent cardiac complications existed . . . . . 24. 28.57 "
Number of cases in which recent and old cardiac complications existed . . 36. 42.85 "
Average number of days of duration before treatment of recent cardiac complications, 14.2.
Average number of days of duration after treatment of recent cardiac complications, 17.3.
Total number of days of duration to dismissal of case . . . . . 31.5.
Average number of days of duration before treatment of *no* R. C. C. . . . . 7.2. (60 cases.)
Average number of days of duration after treatment of no R. C. C. . . . . 17.2. (60 ")
Total number of days to dismissal of case . . . . . 24.4. (60 ")
Average number of days of duration before treatment of no R. nor O. C. C. . . 6.02. (36 ")
Average number of days of duration after treatment of no R. nor O. C. C. . . 14.30. (36 ")
Average number of days to dismissal of case . . . . 20.32. (36 ")
Total number of cases indicating endocarditis . . . . . 22.
Number of cases marked *slight systolic apex* murmur . . . . . 8.
Total number of cases indicating pericarditis . . . . . 5.
Ratio of pericardial to endocardial . . . 1 : 4.25.
Left side of heart involved in . . . 22 cases.
Right side of heart involved in, . . no "
Acute *pleuritis* complicating in 4 cases (1-21).
Acute *lobar pneumonia* complicating in 1 case (1-84).
Suppurative endocarditis and suppurative myocarditis, 1 case.

TEMPERATURE.

Average tempt. on first day seen, . . . 101.6
Average pulse rate on first day seen, . . 93.7
Highest tempt. on any day, ... 104.9
Highest pulse rate on any day, . . . 121.0

RESULT.

Of the total cases, ... No. 84
Died, ... 3
Improved, dismissed or passed out of notice, . 8
Cured, ... 73

Of the 36 cases with an average duration before treatment of 6.02 days only one developed any cardiac complication as has been mentioned above.

Of the remaining 48 cases, 21 had developed heart complication, which in no case could be attributed to purely functional causes in either the present attack or supervening upon an old trouble, similarly acquired.

Of these 21 cases one did not yield to the specified treatment, but continued to develop attacks at rather frequent periods for the next fifteen months while under observation. In this case, however, the patient did not bear the drugs well, not being able to take but very small doses, and those for only a short period; and when it is remembered that this case, then only fifteen years of age, had been suffering from annual attacks ever since nine years old, and at the time of observation presented a marked murmur of mitral insufficiency, our faith on account of this failure should not wane.

Of the 8 cases noted "Improved" one had been sick three weeks and had suffered from A. A. rheumatism before. Another had been sick 9 weeks.

Another had been sick 29 days. Another, the case of the girl 15 years old (other treatment used). The remaining four were treated with other additional drugs on account of the salicylates not being well borne.

Of the three cases noted "Died," one, although seen before the fifth day of sickness, had already developed acute ulcerative endocarditis, and on the second day of observation a profuse petechial eruption on arms, legs and back.

Singularly this patient lived nine days longer or nearly sixteen from onset of attack.

Autopsy revealed suppurative endo-, peri- and myo-carditis. Both apices of lungs presented old tuberculous nodules with pleuritic adhesions. A small suppurative foci in spleen and liver.

The 2nd case, when first seen had been sick one month. Had suffered from A. A. rheum. two years before and presented at time of observation a marked murmur of mitral insufficiency. Patient lived thirty-one (31)days longer. Autopsy revealed acute pericarditis, acute double pleuritis, and acute lobar pneumonia. The patient, a female, was forty-eight (48) years old with an alcoholic history. The 3rd case, a man, aged 60 years, had suffered from A. A. rheum. several times before. Presented on examination which was made twenty-one days after onset of attack, marked mitral regurgitation and mitral presystolic murmurs. Lived six days longer. Autopsy revealed acute double pleuritis with effusion and rather recent endocarditis engrafted upon old valvular trouble.

From the foregoing study the writer has felt constrained to draw the following brief conclusions:—

(1) That acute articular rheumatism is a specific disease due to some morbific principle or infectious agent circulating in the blood.

(2) That whatever that principle or agent, the salicylates tend to either destroy it or prevent any further formation.

(3)That in substantiation of some acid factor as a cause, though possibly only as a complication, the author noted a constant acid condition of the urine, and a neutral or acid state of the saliva in 80 per cent. of the cases examined.

(4) That the disease is self-limited with a tendency to recovery within a variable period.

(5) That while self-limited, cases are very prone to develop cardiac complications as in direct proportion to the polyarthritis, this is not the invariable rule—having many notable exceptions. The same thing may be said regarding the constitutional phenomena.

(7) That under the salicyl-alkaline treatment these or other complications are either absolutely prevented, in the vast majority of cases, or their severity mitigated.

(8) That drugs to reduce the heart's action, thereby lessening the tendency to valvular complications by relieving the valves of extra amount of work thrown upon them, are seldom indicated, the salicylates sufficiently controlling.

(9) That acute articular rheumatism is a disease likely to develop again in those once attacked, and that with each subseqent attack the tendency to cardiac complications increases.

(10) That this tendency to recurrence seems to the writer to disclaim rather than to substantiate the theory of its infectious nature.

(11) That the writer does not believe the statement that the salicylates render subsequent attacks more probable, since

of the thirty-one (31) cases of recurrent acute articular rheumatism recorded, but very few of them could give a history of having taken similar treatment before; furthermore such a proposition can not be based upon any plausible hypothesis.

(12) That the above mentioned treatment shortens the duration of the attack particularly the very acute stage, relieving pain often within a few hours from the time of saturation.

(13) That the period of saturation is variable, depending upon the amount of the drug that can be borne by the individual.

As the salicylates appear in the saliva and urine often within twenty minutes after administration, and the physiological phenomena manifest themselves within six hours, it is fair to assume that by the time the patient has taken four or five doses of fifteen (15) grains each, the condition of saturation is approximated, and within twelve to twenty-four hours attained.

(14) That while the duration of cases reported seems as long as or longer than the average cases under other treatment, the time computed represents a supposed absolute freedom from any further rheumatic influence, many of the cases appearing well several days before discharge.

(15) That from the observation of the above and other cases, the writer is led to believe that the treatment should be continued, three or four days at least, after all objective and subjective symptoms have disappeared, for since the poison may circulate in the blood for a variable time, producing endocarditis, even before any definite articular symptoms appear, in like manner may it continue for several days after cessation of these symptoms.

(16) That if this fact, if it be a fact, were more generally recognized, fewer cases of so-called relapse from salicyl-alkaline treatment would be reported.

(17) That if all cases could be put upon the above treatment at least within six days after first symptoms have manifested themselves, the subsequent course of the disease would be mitigated, and serious complications often prevented.

(18) Deductions with reference to influence of occupation, etc., as ætiological factors are mentioned under tabulated statistics. The same may be said of frequency of extremities and joints involved, etc.

THE CIRCULATION IN THE BRAIN AND EYE WITH INCREASED PRESSURE AND GLAUCOMA.

By P. I. LEONARD, M. D.,
ST. JOSEPH, MO.

Circulatory disturbances in the brain and eye with regard to increased intracranial and intra-ocular pressure have many points of resemblance.

They are respectively enclosed within a firm capsule of an unchangeable capacity. Both organs are subject to pressure as a result of the circulation of the nutritive juices. In both instances this pressure, when it goes beyond physiological variations, affects the optic nerve, producing a papillitis "choked disk," or, an excavation of the optic nerve.

The functions of the brain and eye depend on a normal circulation in most delicate structures, hence, the inflow and outflow must be balanced and any brief obstruction may give rise to a serious disorder.

Another resemblance we see pathologically where increased pressure in both organs is the most frequent result of atheromatous degenerations or inflammatory changes of the vessel walls with their consequences.

The brain while filling the cranial cavity has many external communications through the entrance and exit of the blood-vessels, lymphatics and nerves, but they fill out their foramina completely. The spinal cavity is capable of a change in volume as the membrane obturatoria atlantis posterior and anterior, the ligamenta flava and the sheaths of the intervertebral foramina are capable of distension.

If the subarachnoidal spaces of the spinal cord are injected with a colored solution, this extends quickly over the surface of the brain, passes through the foramen Magendie into the fourth ventricle so on until finally it fills the central canal of the spinal cord (*Key. Retzius, Althan*). It is suggested that the subarachnoidal spaces communicate with the

lymphatic vessels of the brain and pia mater, that the latter unite at the entrances of the arteries at the base of the brain and pass down as the plexus jugularis interna.

In the arterial system of the brain there is a positive pressure which propels the blood while the outflowing circulation is under a negative pressure in the veins. Still another factor is found in the ventricles and lymph spaces which contain the cerebro-spinal fluid. If the brain is so compressed that pressure is exerted upon the ventricles there will be increased pressure of the csp. fluid in all the spaces, and the ligaments of the spine bulge outwards. Experiments do not show that increased tension of the csp. fluid compresses the brain and renders it anæmic. Anatomists are not certain whether the csp. fluid stands in communication with the lymphatic vessels.

Adamkiewitz says experimenters who inject saline solutions into the spaces filled with csp. fluid do not compress the brain by increased tension, but from the irritation produced by the experiment, and, according to the same authority, neither experiments nor clinical experience have furnished sufficient supporting evidence to construct a theory of compression of the brain.

It is generally accepted that the brain pulsates, that the csp. fluid flows to and from the spinal into the cranial cavity, that there is a systolic and respiratory movement, and finally, Cramer claims that the veins of the brain pulsate. This phenomenon is explained in the following manner. In heart systole the mass of blood receives an additional amount and the tension of the csp. fluid is increased. As the blood pressure diminishes gradually from the arteries to the capillaries and so on to the veins, the veins are that part of the vascular system in which there is least pressure and consequently the one which can be compressed with the greatest ease, The increase in pressure being rhythmical. the compression of the veins is rhythmical—remittent, and they must show pulsation.

When in passive hyperæmia the outflow of venous blood from the cranial cavity is obstructed, the arterial supply will naturally meet with an obstruction. When the contractile condition of the vessel wall is lost a part of the blood pressure is transmitted to the csp. fluid.

When then the tension in the cerebro-spinal cavity can no further accommodate itself by distension of the spinal ligaments, arterial hyperæmia compresses the capillaries of the brain.

Hyperæmia and anæmia would thus appear to disturb the nutrition of the brain in the same manner and lead to similar disturbances of function. Knoll claims to have observed the cranial arteries after a temporary anæmia when refilled with blood under a certain pressure, to relax and produce hyperæmia.

Cramer says in experiments which raise the blood pressure in the aortic system the cerebro-spinal pressure is augmented and an increased outflow of venous blood, the result. Pressure in the brain is then transmitted from the blood to the csp fluid on to the dura.

The blood-vessels of the brain with their perivascular spaces, the ganglion cells with pericellular spaces, with large spaces containing the csp. fluid, the structure of this organ protects its more delicate tissues trom the variations of physiological pressure.

One of the most prominent symptoms of intra-cranial pressure is "choked disk."

Descending neuritis is observed in diseases of the cortex, in diffuse maladies, principally acute and chronic meningitis and hydrocephalus. Choked disk is most frequently seen in tumors of the brain. The gradual growth of a tumor demanding more and more space, displaces the cerebro-spinal fluid, and also fills with fluid the spaces between the sheaths of the optic nerve which stand in communieation with the lymph spaces between the cerebral membranes—hydrops vagina nervi optici—Schmidt, Mauz.

This accumulation of fluid brings about a stasis of the lymph in the optic nerve itself, especially in the lamina cribrosa. The œdema of the lamina cribrosa causes a compression of the central vessels and as the diminished caliber of the central vein fails to return the blood, we get a venous stagnation and swelling of the optic nerve. At the scleral ring we may have even an incarceration or strangulation followed by a high degree of œdema.

Ophthalmoscopically, in choked disk the swelling is considerable but stops suddenly at the margin of the papilla; sometimes we notice a hyperæmia of the retinal veins.

In neuritis descendens the papillary swelling is small while the exudation causes a discoloration of the disk and extends into the retina giving us the picture of a neuro-retinitis.

These two forms of neuritis cannot be strictly differentiated, as they pass frequently one into the other.

The eye, for purposes of study, can also be considered inclosed in a capsule containing fluid. The contents of this capsule exert a pressure upon its inner surface, which, according to hydrostatic laws is transmitted with equal force upon every part, and the lamina cribrosa as its weakest point shows the earliest sign of an augmented tension. The crystalline lens is held in position by the zonula zinii forming a diaphragm, which divides the inner contents of the eye ball and under normal conditions is elastic and may be pushed either way. Augmented tension with the zonula zinii drawn tense, etc., as frequently happens, pressure may vary in the aqueous from the vitreous humor. This does take place when the aqueous humor escapes and the lens is pushed forward, the difference in pressure of the vitreous increase filtration and refills the anterior chamber. Deutschman argues that repeated paracentesis causes an increased metabolism of the vitreous, an observation which might be of use in the treatment of its diseases. The contents of the eye ball with a variable volume are the aqueous and vitreous humors but it is principally the blood which by increase or decrease in blood pressure in the inner coats of the eye may cause a corresponding change in intra-ocular pressure. Under physiological conditions there are small variations. Temporary influences which raise the pressure in the entire vascular system are balanced by an increased outflow of fluids from the eye.

Glaucoma is a disease characterized principally by increased intra-ocular tension, by the excavation of the optic disk and the disturbance of vision consequent upon these morbid changes. Augumented tension and an excavated disk without a previous disease to account for them, is called primary glaucoma, when another intra-ocular disease is present, secondary glaucoma.

Primary or real glaucoma generally affects both eyes, even if not at the same time, while secondary glaucoma is limited to the eye which gave rise to it.

Among the many theories advanced to account for the increased intra-ocular pressure in glaucoma those of Grafes Doudens, Stellevog, Knies and Weber are the most important but they fail to give a suitable explanation for all cases. The theory of Weber refers increased tension to an obstructed excretion, retaining an increase of fluids within the eye. At present this theory has the largest number of adherents.

As the chief factor in the development of the glaucomatous process we must regard the senile degeneration and dilatation of the uveal vessels, a condition found in nearly all cases by pathological anatomy. These vascular changes in the capillaries, principally of the interior portion of the uveal tract, produce a chronic increase in the volume of the blood, causing a slight transudation and increased escape of fluids and plastic elements into the anterior half of the bulbus. Consequently we have an increase intra-ocular pressure with its consequences. In this manner we obtain a typical glaucoma. But augmented tension as in attacks of severe iritis, for instance, and glaucoma, are by no means identical conditions. A correct diagnosis of glaucoma is of the greatest importance as an early therapeutic interference may save the sight of the patient. To enable us to do this we must take into view a number of conditions. We cannot rest the diagnosis of glaucoma upon a single symptom.

Attacks of hemicrania with gastro-febrile symptoms should warn the physician to look for the possibility of a glaucoma and make a thorough examination of the eye. After these symptoms we may have an increased tension of the eyeball, loss of corneal sensibility, enlarged pupils, diminished accommodation and a shallow anterior chamber. The optic media become cloudy.

Inflammatory glaucoma may be mistaken for iritis or iridocyclites and a treatment with atropia can do great harm. The frequent indiscriminate instillation of atropine, or even homatropine and cocaine in eye diseases, cannot be too strongly discouraged, especially in elderly people. To differentiate between an inflammatory glaucoma with ciliary injection, a discolored iris, and iritis, leaving augmented tension aside, in iritis we have a contracted pupil, in glaucoma it is dilated.

Atropine should only be used when directly indicated and stopped when the desired effect is obtained. Simple glaucoma without any inflammatory signs may be diagnosed for a beginning cataract when no ophthalmoscopic examination is made.

When increased intra-ocular tension is found as a complication of another pre-existing disease, it is termed secondary glaucoma, and here we can observe the characteristic consequences of a primary glaucoma.

NOTE ON THE HYSTERICAL CONCOMITANTS OF ORGANIC NERVOUS DISEASE.*

By C. H. HUGHES, M. D.,
ST. LOUIS, MO.

The conclusion, "Some hysteria, *ergo* all hysteria," is a clinical conclusion which has proven in numberless instances fatal to correct diagnosis and to the welfare of many patients.

This neurosis may be latent as any other inherent tendency to neuropathic instability may be and often is, until some physical or pathological cause calls it into morbid activity. While hysteria is essentially an imitative and functional disturbance of the psychomotor, sensory and ganglionic centres, it is no more unreasonable to expect its development in conjunction with grave organic lesions of the cord or brain, than to anticipate pain or spasm from profound central disease or even from multiple neuritis of the motor nerves extending to the cord centers or involving contiguous peripheral sensory nerve fibers.

The time has fully come, in the progress of neural pathology and clinical neurology, to recognize this fact and realize its true significance in our clinical judgments, for without such proper recognition we may be too often led astray in diagnosis and prognosis for our patient's welfare or our professional reputations before a scrutinizing and discerning public. Hysterical patients are prone to develop peculiar inherent neuropathic characteristics of their organism under physical as well as psychical stress and this physical strain may be a real central or peripheral structural disease.

It has been quite a number of years since the writer first began to think in this way and ample observation has confirmed the correctness of his earlier judgments, though not until after some serious clinical errors had been recognized after the issue had been determined post-mortem.

So far back as 1867, 1868, 1869, 1880 and 1881, several of my autopsies at the Fulton Asylum for the Insane on patients who had died of organic disease of the brain and other organs, some of whom had been pronounced only hysterical in the communities from which they came and one or two of whom had hysterical seizures while they lived in the institution, set the author to thinking on this subject and led to a final revision of his previously entertained view that hysteria was always a functional nerve trouble.

It was not long after leaving the asylum that a very markedly instructive case, because of its tragic ending, fell under our observation.

The case was that of a lady past the menopause, and mother of several grown children, who suffered from disseminated sclerosis, with characteristic pupillary changes, intention tremors and insomnia, and with numerous hysterical symptoms and frequent paroxysms.

Her case had been pronounced by old and experienced physicians to be hysteria and hypochondria (which latter, by the way, is another much misapplied term because it, too, does really, though less frequently, co-exist with grave physical lesion).

A multiple neuritis co-existed in this case and she had exacerbations of neuralgic pains.

This woman really suffered physical agony, but the verdict of her family physician and a consultant from the city that the case was hysteria, lost her the sympathy of her husband and children which she deserved and craved, and in her despair, chagrin and grief she took her life.

Thos. Buzzard, in his presidential address before the London Neurological Society in January, 1890, has caught a glimpse of our subject in a little different light. The essay as since published by Churchill, of London, is entitled, "The Simulation of Hysteria by Organic Disease

*Read before the Neurological Section of the American Medical Association.

of the Nervous System." In this little brochure the fact has not escaped this able clinician's observation that hysterical symptoms may co-exist with even so grave an organic disease as disseminated sclerosis, but he thinks it is the sclerosis which causes symptoms which simulate hysteria, whereas we think the hysteria is real and the sclerosis is the *casus mali* that brings into prominent morbid activity the latent functional neurosis.

He even makes certain hysterical symptoms a necessary part of the organic disease he is discussing. We quote: "It appears to me reasonable to conclude that many symptoms which have come to be considered characteristic of hysteria will, if examined in the light of improved knowledge and experience, be regulated to disseminated sclerosis. The figure of hysteria shrinks in proportion as the various forms of organic disease acquire greater solidity and sharper definition."

But we have not always found this to be strictly true except as the fatal ending of disease approaches. We have in view one instance in a male which though death is impending from probable syphilitic and gummata with cerebral congestion, the patient has numerous crying spells with spitting out of food and medicine and violent tendencies at times followed by laughter and tranquility. The congestion of brain has evidently a malarial complication with cold stage, fever and sweating, reaction and intervening better days.

Buzzard's book is good reading *a propos* of our subject and bearing in mind the difference of view, viz., that in our opinion the hysterical symptoms are always brought to the surface in persons who have this neuropathic diathesis and in no others by the irritation of an organic disease, while Buzzard regards the hysterical symptoms as necessary signs of the organic disease. He has found hysterical symptoms in Frederich's ataxia and secondary cancer. We have one of the latter cases now under treatment or rather as a sequence to a second removal, the patient having, also, been really insane with delusions of electricity, etc., and periodicity of exacerbation as of malarial poisoning.

He details a case of hysterical paraplegia dependent on atrophy of the illio-psoas muscle and a number of cases of disseminated sclerosis mistakenly diagnosed as hysterical, one of them in a male patient and one case like our own terminating fatally.

We remember to have seen one case of posterior sclerosis in a female in which the pharyngo-laryngeal crises were so distinctly intermittent and the sensation of globus was so like that of hysteria that we were often uncertain as to whether the patient did not really have the true globus hystericus from the irritation of the changes in the pons and medulla and the reflected gastric crisis. She had other hysterical symptoms and had in her earlier life been a victim of this neurosis spasmodic. She died however in a cardio-laryngeal crisis.

In the recent publication of the Salpetriere Cliniques,* Volume I, 1892, Charcot relates a case of Morvan's disease complicated with hysteria and several cases of hysterical tremblings having associated variations of intention tremor and vibratory tremor. These were probably, as they were apparently, associated with sclerosis.

Five days ago a lady now dead of cerebral congestion, came to my office at the instance of Dr. Mayger of this city with general hysterical trembling. Her history had been one of mental shock and over nerve strain.

I have seen a case of abscess of the cerebrum following a cerebritis preceded by hysterical symptoms till near the close, and a school teacher of twenty-two years overworked and anxious about her ability to continue teaching developed hysteria along with general neurasthenia and malarial poisoning, the latter ending in cerebral congestion, temporary insanity and death—the hysterical symptoms disappearing as the gravity of the cerebral increased.

Hysteria sometimes displays itself in connection with epilepsia mitior as well as in the grave form of hystero-epilepsia. It has been developed in my observation after diphtheria, scarlatina and rheumatism. In these instances I have always found a family history of this or other form of spasmodic neurosis. It is not uncommon

*Clinique des Maladies du Systeme Nerveux, M. le Professeur Charcot pendant les annees 1889–90 et 1890–91 sous la direction de Georges Guinon Chef de Clinique. Publications du Progres Medical.

"Relation d'un cas type de maladie de Morvan complique d'hysterie. Superposition des anesthesies hysteriques et de Morvan chez le meme individu."

in ordinary chorea especially later in life after an earlier chorea, one of my present cases of chorea major shows hysteria markedly. But these are both ordinary functional nervous diseases.

I think I have seen it in one instance brought out during the convalescence from hemiplegia as chorea sometimes appears.

With these clinical facts before us, are we not justified in extending our search for hitherto unsuspected organic disease of the nervous system as causes of hysterical symptoms, as well as in looking to the womb for the fountain source of this symptomatic neurosis and in relegating to the back-ground the prevailing clinical dictum that, "Where hysterical symptoms present, the trouble is only a functional one of the nervous system?"

It is undoubtedly true, as Buzzard has clearly shown, that hysterical symptoms develop *de novo* only in part and as part of the expression of organic nervous disease. I have seen such cases—cases where the mind was for quite awhile in doubt as to the real nature of the disease—whether organic or functional. As one may see paralysis appear and find the cincture feeling present and the knee jerks absent in hysteria sometimes, so may he see symptoms of hysteria in real organic disease. I may note here a case of salam tremor or rhythmical contractions of the sterno-mastoids, long suspected by myself to have been hyterical, which proved to have been caused by cervical pachymeningitis of which the patient subsequently died.

As this is but a note of clinical warning we trust this word may prove sufficient to the wise clinician and with a brief quotation slightly qualified to compass our own view we close this paper as Buzzard has introduced his able address, our object being, "to draw attention to the frequency with which symptoms liable to be looked upon as (solely) hysterical are found to be really due to structural changes in the nervous system" as the exciting if not solely causative factor.

ANTIDOTE TO PHOSPHORUS.

In cases of poisoning by phosphorus Bokai and Korányi recommended a 1-5 to 1-3 per cent. solution of potassium permanganate. Brought in contact with this, the phosphorus is transformed into harmless orthophosphoric acid.

Correspondence.

LETTER FROM A SPECIAL CORRESPONDENT.

LONDON HOSPITALS AND WANT OF FUNDS.

I find that London suffers from the same difficulties that we do in Philadelphia, in spite of all its wealth; namely the want of funds to sustain the hospitals. The various appeals which have been made by means of friends and the press, with concerts, flower-shows and all the ordinary measures to obtain sufficient means for sustaining them, have failed, and more recently they have adopted the Hospital Sunday Collection for which there was on the tenth day of June an appeal made by the various clergymen to their congregations for funds, yet, according to the *London Times*, the Hospital Sunday has not become the entire success which it promised to be in the beginning.

It is stated that apparently, some people imagine that by giving on that day, they free themselves from the necessity of extending further assistance to the associated physicians and surgeons.

Each Hospital should receive a certain amount 'per capita,' or patient when they have been treated as an in-patient, and for out-door relief there should be a small sum paid by each patient for medicine, which, if judiciously employed, will almost entirely defray the expenses attending upon this class of cases.

SALARIED RESIDENT HOSPITAL PHYSICIANS.

Another subject has recently been discussed by the medical press of England, namely, salaried hospital physicianship, owing to the difficulty of obtaining the services of a resident honorary physician. This is especially the case in agricultural districts, but it holds good in small hospitals in cities, especially in poor neighborhoods. It has been noticed that since the appointment of a salaried physician the income of the hospital (more especially at Colchester) has steadily increased and more than pays the thousand dollars salary.

The following statistics show the fluctuations in the hospital income and work for two years preceding, and the four years succeeding, the change:

	Hospital Saturday Collections.	Hospital Sunday Collections.	Annual Subscriptions	Out-patients' Fees, 1 s. per Letter.*	Total Income of Hospital.	Number of In-patients admitted.	Number of Out-patients treated.
	£	£	£	£ s.	£

EARNINGS OF DOCTORS IN ENGLAND.

Mr. Goschen, Chancellor of the Exchequer in 1892, drew a very roseate picture of the earnings of professional men, lawyers and doctors, in England, when he compared the income derived from them with what he received with cotton spinners. Some of the lay papers have already drawn attention to the fallacy contained in his budget speech. As regards medicine we need only say that it has been repeatedly proved that the income of the medical men does not exceed 200 pounds sterling, or $1000, a year, and out of this must be paid rent, taxes, rates, the expense of the household, of horse, carriage and groom, and all other items incidental to existence.

The money in each locality is returned to the butcher, baker, tailor and when the practitioner enjoys a larger income, he makes a much larger return to the community amongst which he lives in the increased style in which he lives.

An income of $1000 a year, presuming that a medical man is married and has children, does not allow of extravagance in living.

The moiety of income tax due upon that sum becomes a very great tax for the practitioner, and is one which he cannot well afford to pay.

LAWRENCE TURNBULL, M. D.
London, England, June 12th, 1892.

* One shilling is paid by each out-patient, on admission, the letter lasting three months.

† The total increase, therefore, from the four first-named sources, is £279, so that after paying the physician's salary a sum of about £80 comes into the general hospital funds from these sources.

Selected Formulæ.

THE TREATMENT OF TAPE-WORM BY THE EXTRACT OF MALE FERN.

The administration of male fern in the treatment of tape-worm is reviewed in the *Province Medicale*, No. 4, 1892, *Journal de Médecine de Paris*, May 1, 1892, as follows:—

1. Crequy's prescription:

℞ Extract of male fern.....8.00 grammes.
Calomel.....0.80 gramme.
M. and put into eight capsules. Sig.—Two capsules every ten minutes.

2. Peschier's formula:

℞ Extract of male fern .....2.50 grammes.
Gum arabic.....1.25 grammes.
Powder of tin.....1.25 grammes.
Calomel.....0.60 gramme.
Medicinal soap.....0.60 gramme.
Powder of fern root.....q. s.
M. and make twenty pills. Sig.—Ten pills at ten o'clock at night, and the other ten an half hour afterwards.

3. Madame Nuffer's formula:

℞ Powder of male fern..... 6.00 grammes.
Water.....125.00 grammes.
M. Sig.—To be taken at once in the morning, before breakfast, to be followed one hour afterwards by a purgative, such as calomel or scammony.

4. For children:

℞ Ethereal oil of male fern.... 0.50 to 1.00 gramme.
Calomel..... 0.50 gramme.
Water.....15.00 grammes.
Powdered sugar.....15.00 grammes.
Gelatine..... q. s.
M.

—*Jour. de Médecine de Paris*, May 1, 1892.

FOR CONSTIPATION.

℞ Aloin.....1¼ centigrammes.
Extract of belladonna.....6 milligrammes.
Ipecacuahna.....3 centigrammes.
Strychnine.....1 milligramme.
M. and make one pill. Sig.—Night and morning

—*Jour. de Médecine de Paris*, May 1, 1892.

IN CHLOROTIC DYSMENORRHŒA.

The following combination is recommended by Monin (*Jour. de Médecine de Paris*, May 1, 1892):

℞ Tincture of balm-mint.
Tincture of saffron.
Tincture of iodine, of each.....15 grammes.
M. Sig.—Twelve drops before the principal meals. Every eighth day a warm bath, to which 125 grammes of chlorhydrate of ammonium should be added.

ANALGESIC MIXTURE.

As an analgesic combination the following is recommended (*Jour. de Médecine de Paris*, May 8, 1892):

℞ Menthol.
Chloral.
Camphor, of each.....10.00 grammes.
M. until liquefacation takes place. Sig.—Apply locally in toothache, rheumatism and neuralgia.

THE THERAPEUTIC USES OF CHLORHYDRATE OF AMMONIUM.

In reviewing the therapeutic uses of chlorhydrate of ammonium, Ch. Liegeois (*Rev. Gener. de Cliniq. et de Therapeutique*, April 30, 1892) recommends the following formulæ:

1. In convalescence of *typhoid fever*:

℞ Syrup of marshmallow.....250.00 grammes.
Syrup of squill..... 32.00 grammes.
Ammoniated gum.
Wine of antimony.
Chlorhydrate of ammonia, of each, 8.00 grammes.
M. Sig.—Several spoonfuls during the day.

2. In *Dysmenorrhœa:*

℞ Chlorhydrate of ammonia.....300.00 grammes.
Water..... 6.00 grammes.
M. Sig.—A dessertspoonful, night and morning, before the arrival of the period.

3. In chronic *pelvic peritonitis:*

℞ Chlorhydrate of ammonium..... 50 grammes.
Simple syrup.....500 grammes.
M. Sig.—One to five dessertspoonfuls a day, taken at meal time, in a little water.

4. As an *antiperiodic:*

℞ Powder of red cinchona bark.
Chlorhydrate of ammonia, of each, 4.00 grammes.
Syrup of puinpuina..... q. s.
M. Sig.—One half to be taken immediately after the access, the other half six hours before.

THE TREATMENT OF PRURITUS.

The following combinations are recommended in the treatment of the different forms of pruritus (*Jour. de Médecine de Paris*, May 8, 1892):—

1. Doyon's lotion:

℞ Oil of almond.....500.00 grammes.
Corrosive sublimate..... 0.20 gramme.
Chloride of ammonium..... 0.25 gramme.
M.

2. Vidal's lotion:

℞ Rose water..... .....250.00 grammes.
Hydrate of chloral..... 8.00 grammes.
M. Sig.—After the lotion, some starch is applied.

3. Hardy's ointment:

℞ Vaseline.....20 00 grammes.
Cyanide of potassium..... 0.10 gramme.
M.

4. Besnier's ointment:

℞ Vaseline.....30.00 grammes.
Cocaine..... 0.30 gramme.
M.

5. In pruritus of pregnancy:

℞ Warm peppermint water.....1 glassful.
Borax.....4.00 grammes.
Essence of allspice.....5 drops.
M. Sig.—Apply with a soft sponge.

6. In eczematous vulvar pruritus:

℞ Olive oil.....30.00 grammes.
Iodoform..... 0.25 gramme.
M. Sig.—Locally applied.

7. Persy's formula:

℞ Phenic acid..... ..... 1.30 grammes.
Tincture of opium..... 15.00 grammes.
Hydrocyanic acid..... 7.50 grammes.
Glycerine..... ... 15.00 grammes.
Distilled water.....120.00 grammes.
M.

8. P. Menier's formula:

℞ Pulverized talc.....15.00 grammes.
Bichloride of mercury..... ..... 0.50 grammes.
Dried extract of valerian ..... 2.00 grammes.
M. Sig.—Apply twice or three times a day.

RESECTION OF THE OS CALCIS AND ASTRAGALUS.

Dr. Bogdanik describes the following procedure: The operator stands on the right side of the patient, and makes an incision beginning closely beneath the external malleolus, if the operation is performed on the left foot, but beneath the internal malleolus if on the right. The incision penetrates to the calcaneum and extends obliquely downwards and backwards, in the direction of the annular ligament and at a distance of one centimetre from the sole of the foot, toward the other malleolus. The calcaneus is sawed through in the same direction, while the foot is pressed by an assistant against the leg. As soon as the bone has been divided the foot can be readily folded back, so that the dorsum is in contact with the anterior surface of the leg, permitting an inspection of the ankle joint. The astragalus can now be grasped with bone forceps and removed with knife and scissors. It is of advantage to prolong the incision over both malleoli in the direction of the tendo Achilles, because this enabled us to draw upward the upper portion of the calcaneus. It is further advisable to retract the arteries and tendon with blunt hooks so as to prevent their injury by the knife. If the calcaneus is diseased the affected portion may be chiselled out, curetted, or, if necessary, the entire bone may be removed. After the removal of the astragalus the articular surface of the tibia and fibula can be readily brought into view.

The author has performed this operation on two patients and claims for it the following advantages:

1. The incision in the soft parts is small.
2. Injury of the vessels, tendons, muscles or nerves is avoided.
3. The situation of the scar is favorable.
4. Configuration of the foot is preserved.

Leading Articles.

THE THERAPY OF ABORTION.

There is considerable difference of opinion upon many points regarding the therapy in cases of abortion where part or all the fœtal matter is retained within the uterus. While Winckel and other authorities both in this country and abroad suggest in such cases in which there is no fever, putrid discharge or hæmorrhage an expectant treatment, on the other hand Schrœder, Olshausen, Fritch, Veit and many others lay great stress upon the necessity of the immediate removal of the ovum and decidua. An important paper on this subject has appeared from the pen of Dr. Kuppenheim in the *Deutsche med. Wochenschrift.* He reports the results obtained and the therapy used in 84 cases of abortion treated in the Women's Clinic of Heidelberg, and his article has been discussed editorially in a recent issue of the *Medicinische Neuigkeiten.*

The course of seven cases out of these eighty-four cannot properly be taken into consideration, as only a single rise of temperature to 38° and 39° C. characterized an unusual condition of the patients. In seven other cases the patients when they came for treatment already had high fever, and were severely ill in consequence of the delay of proper treatment; one, indeed dying from sepsis. In these eighty-four cases digital removal of the ovum and decidua was practiced thirty-two times, and the curette was used in fifty-two cases. Three out of the first group and four out of the second succumbed.

Prior to the digital removal, the vagina, cervical canal, and if possible the uterus, should be syringed or washed out with a proper antiseptic solution such as a three per cent. carbolic acid solution or a 0.25 per cent. solution of bichloride or mercury, and a similar washing should be pursued after the operation.

The curette was used in cases of retained ovum in the second and third months of pregnancy, and only in the later months when after the digital removal of the ovum a retention of a portion of the decidua was suspected. The curette was always used with the patient in the Sim's position, after careful disinfection of the parts, and without anæsthesia. Recumier's curette was generally employed. The remnants of the decidua are scraped away with the curette in closely-lying parallel lines, care being taken not to injure the entrances of the tubes. Especially during the first three months of pregnancy, when the narrowness of the cervix precluded the possibility of digital removal without dilatation of the cervix, the operation of curetting is preeminently adapted for this purpose. In many cases, even after the digital operation has been sucessfully carried out, the curette will bring away shreds of membrane, and it is very often these that cause the most severe hæmorrhages. As a most important advantage of the curette, Kupperheim speaks of the fact that for its use the cervix need not be dilated. Another advantage is that its use causes but very little pain, so that the operation can safely be undertaken without anæsthesia. Kuppenheim is of the opinion that the danger of perforating the uterus by the curette is decidedly exaggerated by the majority of gynæcologists.

Regarding the other therapeutic means employed, we must mention that of cauterization with a ninety-five per cent. solution of carbolic acid. This was used by Kuppenheim in all cases that came to the clinic in a state of infection. The carbolic acid is applied by a sound with a pledget of cotton wrapped on the end, or with a piece of cotton held in a polypus forceps. The results of this treatment were, that in six cases the fever fell at once, and in one case a pelveo-peritonitis ceased. The cauterization with carbolic acid has other advantages, it stimulates uterine contractions and acts beneficially in checking existing endometritis.

For the checking of hæmorrhage consecutive to abortion, Dührssen's application of chloride of iron has long occupied a position of prominence; the iodoform gauze tampon will, however, usually be found of greater service.

The after-treatment consists besides a confinement to the bed for eight days, in vaginal douches and the administration of ergot.

Briefly summed up, Kuppenheim's belief is that during the first three months of pregnancy the fœtal remains should be removed manually and with the curette; that in the later months the manual method alone may often prove efficient in itself, and that the placenta should always be removed manually, but fragments of the same can only successfully be removed with the curette.

APPLICATIONS OF COLD IN TRAUMATIC SURGERY.

"It is to be regretted," says Dr. Buch, in a recent number of the *St. Petersburger med. Wochenschrift*, "that while we are fully aware of the valuable properties of cold applications in allaying pain and inflammation, yet we believe ourselves unable to apply it in the very instance where it would prove most useful." Dr. Buch refers to those cases in which the affected parts are covered with an antiseptic dressing or plaster of Paris bandage, and in which the local dressings hinder a direct cooling of the part.

According to Buch's experiences the procedure suggested some time ago by Winternitz is far too little known, and even to a less extent adopted. It consists in a method of cooling the affected limb without necessitating the removal of either dressing or plaster of Paris bandage, and is especially applicable when the injury is in the lower half of the extremity.

Winternitz's experiments have conclu-

sively demonstrated that if the upper part of an extremity be surrounded with ice, the blood-vessels of the entire limb contract. Winternitz explains this effect by a direct action on the vessels, and upon the nerve branches. Buch, however, ascribes the result to a reflex action, for it frequently suffices to place a single piece of ice upon any portion of the upper part of the arm to affect the temperature of the entire arm several degrees.

Winternitz did not fail to recognize the practical value of his discovery and invariably used ice applications as described in connection with the local dressings, and found that by so doing he was able to completely check the inflammation in the parts. The method has not, however, received the attention it deserves. Buch has, where possible, used the central applications of cold in connection with the local, and has obtained, thereby, far more gratifying results than when only local applications were employed. But in other cases, as has been mentioned, where a permanent or fixed bandage precludes the direct use of cold, the application above the dressing then of course is the only one feasible. Buch has obtained the most brilliant results for the past few years in this way. Since he adopted it he has been able to keep iodoform dressings in their place which otherwise on account of the pain they produced would have had to be removed. As soon as the wound began to be painful, Buch would apply a cold pack, or if possible an ice-pack, above the dressing, and found that invariably within a short time the pain would cease, and discovered that by this means he could guide the reaction of the wound at will.

The same holds good for fractures of the extremities. Buch is positive that in many cases the plaster of Paris splint was well-endured solely on account of the presence of the cold above the wound. During the preparation of the splint he applied extremely cold applications to the entire limb in order to reduce the temperature of the parts as much as possible, and as soon as the bandage has been applied, continues these applications above the bandage. In any case, as soon as the plaster splint causes pain, he applies an ice-pack above the splint, whereby he has always been able to control the pain and, in connection with an elevated position of the limb, also prevent the dangerous swelling so often seen.

Buch also lays stress upon the technique of this method, and agrees with Winternitz that *wet* cold is much more efficient than dry cold. Therefore, if the ice-bag is used it should not be placed dry upon the skin, but laid upon a wet compress.

It does seem strange that a method so simple and efficient should not have had the universal adoption it deserves. The use of cold in surgery and medicine will unquestionably be one of the important therapeutic measures of the future.

ON NYSTAGMUS IN AFFECTIONS OF THE EAR.

Dr. Michael Cohn has observed four cases of nystagmus occurring during the course of aural diseases. In Case *I*, of purulent otitis media, the nystagmus was easily produced by the external or internal douche, or even by slight pressure on the tragus of the diseased ear. If a plug of cotton was inserted, pressure on the tragus did not produce the nystagmus, which was horizontal in character and accompanied by vertigo. The purulent discharge soon ceased, but the nystagmus kept on. After electrical treatment it soon disappeared, although the discharge reappeared. In Case *II*, the nystagmus and vertigo were produced by injection of warm solutions. Vertigo also appeared on hearing music. In Cases *III* and *IV* it was caused by the injections of cool solutions. After a discussion of the various theories proposed, the author reaches the conclusion that attacks are most probably caused by an irritation of the semi-circular canals, rather than by a direct irritation of the brain.—*Berlin Klin. Wochensch.*, No 43, 1891.

Book Reviews.

PRACTICAL MIDWIFERY. A Hand-book of Treatment. By Edward Reynolds. Fellow of the American Gynæcological Society, of the Obstetric Society of Boston, etc. Assistant in in Obstetrics in Harvard University, etc., etc., 8vo, 424 pp.. 121 illustrations. New York: Wm. Wood & Co. Price, $2.50.

Few men are better qualified to compile a manual of practical midwifery than the author of this well-written treatise upon the management of labor and the after-treatment of the woman; for he has brought to the task the learning of a large experience and the capacity to well-express his thoughts.

The author does not intend the work to be anything more than a practical manual of the practice of midwifery, wholly in accord with our latest ideas on the subject.

The arrangement of the volume is largely a natural one in dealing with obstetrical medicine, the parts of the book being arranged as follows: pregnancy, normal labor, obstetrical surgery, abnormal labor, the pathology of labor, and the puerperium. The chapters are grouped under the above headings, so that as a useful ready-reference book it will prove of much value to the busy worker. The first chapter enumerates briefly and clearly the essential facts concerned in the diagnosis of pregnancy. Following this the functional disorders of pregnancy and the care of normal pregnancy are considered, this being succeeded by a chapter on normal labor. All discussion of theoretic knowledge is rigidly avoided, and the chief usefulness of the book is in this very fact, which has resulted in the production of a manual containing simply the best and most modern ideas upon the subject of midwifery and surgical obstetrics.

The illustrations deserve mention: in general they are very good and clearly illustrate the points needing emphasis in a work of this character.

We predict for this admirable manual a most cordial reception.

CEREBRAL SCLEROSIS, OF SPECIFIC ORIGIN.

Prof. De Costa prescribed:

℞ Potassii iodidi.....gr. x.
Hydrarg. bichloridi.....gr. 1-40.
Syrup. sarsaparillæ.
Aquæ, āā ad. f3j.—M.
Sig.—Three times a day.

Periscope.

THERAPEUTICS.

ACTION OF OZONE ON THE ORGANISM.

Observers are now agreed in regarding the effects of oxygen on the system as due to its partial transformation into ozone. MM. Labbe and Oudin have concluded a series of interesting experiments bearing upon the physiological action of the latter substance. They found that ozone increases the amount of hæmoglobin in the blood by about 1 per cent. This increase is chiefly in the case of anæmic subjects, whose blood contains only 10 or 11 per cent. of hæmoglobin; individuals having a normal proportion of the latter, 13 to 14 per cent. are unaffected by treatment by oxone.

TREATMENT OF ATHEROMATA.

Lutz (*Monatsheft. f. prak. Dermat.* No. 12., Vol. XIII, 1891.) recommends that atheromata, which have suppurated and those which are thin-walled and very adherent, should be treated by *incision*, the contents are evacuated, the cavity lightly scraped with a curette and then painted with tincture of iodine. He had wonderfully good results and found it much easier and satisfactory than the treatment by *excision*.

ANTIPYRIN IN INCONTINENCE OF URINE.

In a thesis on this subject, Dr. Gaudez has shown the good effects obtained from the use of antipyrin in cases of idiopathic incontinence of urine in children. The author reports 29 cases—14 children completely cured, 12 improved, and 3 unrelieved.

The antipyrin is given either in cachets or in solution, but in either case a small quantity of soda bicarbonate is added to each dose. The dose of antipyrin varies from 1.50 to 4.00 grammes (22 to 60 grains), according to the age of the child. These doses are given in the following way: 0.50 to 1.00 gramme (7½ to 15 grains) at 6 o'clock in the evening; a second dose at 8 o'clock, when the child goes to sleep.

M. Gaudez insists strongly on the hours at which the medicine is given. Sometimes, if the last dose is given at 8 P. M., the child may have involuntary micturi-

tion about 5 A. M.; but if the last dose is given from 9 P. M. to 11 P. M., the incontinence disappears entirely.

These good results of antipyrin have been observed very often from the first day of its use; it is not generally necessary to continue the treatment with antipyrin longer than a fortnight to obtain a permanent cure.—*Gazette des Hôpitaux,* November 17, 1891, p. 1238.

THERAPEUTIC USES OF METHYLENE BLUE.

Constantin Paul (*Sem. Mèd.*, December 30th, 1891) says Desnos's experiments with methylene blue in cases of locomotor ataxy have shown that patients can without inconvenience take as much as 30 centigrammes of the drug daily, and that even when it was given in smaller doses the urine was intensely colored. C. Paul himself found that a dose of 10 centigrammes colored the urine till the third day. After a dose of 5 centigrammes the urine was still colored on the following day, and even to a slight degree on the day after. Gradually lessening the dose, he found that after 2 centigrammes the urine was distinctly colored, and had not entirely regained its normal appearance the next day. Methylene blue being absolutely harmless, C. Paul thinks its administration affords a reliable means of satisfying oneself whether patients are taking the remedies prescribed for them, which may be of practical use in prisons, lunatic asylums, etc. He further hints that the drug may also be employed by way of "suggestion" in order to convince neurotic patients of the efficacy of the treatment which they are undergoing, and as a useful *placebo* when the practitioner wishes to try the expectant method without taking the patient or his friends into his confidence.—*Brit. Med. Jour.*

ON THE EFFECTS OF CHLOROFORM.

L. E. Shaw, M. D., (*British Medical Journal*, November 21, 1891.) gives an account of some experiments made by Dr. Gaskell and himself which were in accordance with those of the Hyderabad Commission. They show that when chloroform is administered without interfering with perfectly regular respiration, complete insensibility can be produced without obvious weakening of the heart's beat. Inefficiency of the heart is brought about by the rapid inhalation of chloroform in too concentrated a form. The practical teachings are that it should be administered slowly, and with plenty of air, and that great care should be taken not to push the chloroform when struggling or gasping respiration occurs.

AN AROMATIC CASTOR OIL.

Dr. Standke (*Norsk Magazin for Lægevinenskaben*, No. 3, 1892) proposes the following manner of preparing an aromatic and well tasting castor oil:

The best oil is treated with warm water several times and saccharin added. This gives a sweet-tasting syrup, which will keep as long as the original oil. If now small quantities of oil of cinnamon and the essence of vanilla be added the last remaining traces of harshness will disappear.

PIPERAZIN.

This substance in aqueous solution dissolves twelve times as much uric acid as is dissolved by the same quantity of carbonate of lithium. There is formed a neutral urate of piperazin, which is seven times as soluble as urate of lithium. Piperazin itself and also the hydrochlorate are easily soluble in water. The dose is from fifteen to forty-five grains a day. It may be prescribed as follows:

℞ Piperazin.....gr. xv.
Aquæ destil.....ʒ vi.
Syrup Aurant cort.....ʒ v. M.
Sig.—To be taken in the course of the day. To be increased gradually.

TREATMENT OF TUBERCULOUS DISEASE OF THE KNEE.

Drobnik (*Centrab. f. Chir.*, No. 11, 1892.) advocates free exposure of the interior of the tuberculous cavity, and long-continued plugging with iodoform gauze as an efficient method of treatment in cases of tuberculosis of the knee, in which both arthrectomy and resection are contraindicated, and no alternative remains save amputation of the limb. The author holds that in all cases of tuberculous disease amenable to surgical treatment, the seat of the disease should be freely exposed and kept open in order to enable the organism to reject the tissues already destroyed or undergoing necrosis. Free exposure of the tuberculous deposit is followed by a profuse secretion of fluid from the diseased

tissues, which drives away the necrosed parts from the immediate neighborhood of the wound, and at the same time establishes in the surrounding tissues increased vital energy, and a more energetic resistance to the attacks of the morbid agents. This discharge continues until the inner surface of the exposed cavity is lined by a thick layer of healthy granulations. In cases in which there are two or more cavities near the joint, the author would make a large opening into each. This method is indicated only in cases of osteal tuberculosis of the knee-joint, and in those in which progressive and destructive disease of the bone necessitates surgical interference. Cases of primary synovial tuberculosis, and of secondary synovial infection in consequence of the communication with the joint of one or more small osseous cavities, are best treated, after the failure of conservative measures—such as extension, rest in splints, and injections—by arthrectomy.—*British Medical Journal.*

GLYCERIN SUPPOSITORIES WITH BORIC ACID.

The use of boric acid as a laxative, when introduced into the rectum, having recently been advocated, Mr Peter Boa thought of employing the Glycerinum Boracis of the British Pharmacopœia. For the purpose of comparison he made two sets of 15-gr. suppositories, one with glycerin alone, and the other with glycerin (or as we say, glycerite) of borax. They were tried practically, and the reports (according to the *Chem. and Drugg.*) were distinctly in favor of those containing boric acid. The simple glycerin suppositories either failed to act at all or acted only very slightly, while those containing boric acid acted in some cases as efficiently as large glycerin suppositories, requiring however , a longer time.

A NEW REMEDY FOR RHEUMATISM.

At a recent meeting of the Berlin Medical Society, Dr. Paul Guttman recommended a new medicament called salophen. It is a finely crystalline substance, easily soluble in ether and in alcohol, but not soluble in water. It consist of salicylic acid and acetylparamidophenol in almost equal parts. Six to eight grammes can be given daily without injury to the patient. It has a slight anti-febrile effect.—*The Lancet.*

THE RELIEF OF VOMITING.

Kenny. (*British Medical Journal*, No. 1618, p. 16) has reported the case of a parturient woman, in whom he overcame obstinate vomiting, resistant to other means of treatment, by the application of a cantharidal blister over each pneumogastric nerve at the anterior border of the sterno-mastoid muscle.

COLOMBO IN THE CONVALESCENCE OF INFLUENZA.

An anonymous correspondent of *Le Progrès Médical*, of Paris, warmly recommends the use of colombo as a tonic and sedative in the convalescence of the grippe. The writer has found it to be an incomparable preventative and curative remedy in the gastric and pulmonary forms of this disease during the last two epidemics. The powder, decoction or an elixer may be prescribed. It causes the appetite to return, the vomiting to cease, and the stools to become regular, while the convalescence is comparatively short and insignificant.

MORPHINE AND ATROPINE.

Stickler (*Centralbl. f. klin. Med.*, March 26th, 1892) says that in cases of poisoning, the antagonism of these drugs cannot be doubted, and that the want of general recognition of the fact is due to the few opportunities of observing it. The unpleasant effects of morphine used as a hypnotic may be prevented by the addition of atropine. In some cases morphine produces excitement, and if it will be still necessary to use it, atropine will antagonize this. A subcutaneous injection of morphine lessens considerably the dilatation of the pupil produced by atropine drops, and an injection of morphine and atropine combined produces only slight dilatation of the pupil. Irritation of the skin sometimes produced by morphine is prevented by atropine. The diaphoretic effects of morphine are sometimes troublesome; they do not occur if atropine be added. On the other hand, the dryness of the skin produced by atropine is remedied by morphine. One of the effects of morphine sometimes seen, and especially in those with early paralysis of the bladder, as in tabes, is retention of urine. Belladonna antagonizes it. Morphine mostly constipates; atropine has the opposite effect, especially in chronic constipation.

In biliary and renal colic the two drugs should be combined, as not only is any obstruction to the passage of the stone lessened, but the power of propelling the stone is increased. In cases of heart disease with engorged pulmonary circulation, morphine is badly borne, whereas the addition of a small quantity of atropine does away with any disadvantages.—*Brit. Med. Jour.*

POISONING BY PILOCARPINE.

A Belgian officer, with an affection of the eyes, was treated by the injection of 2 centigrammes (⅓ grain) of this drug. Immediately his neck, and then the whole of the body, became bathed with sweat; in two or three minutes he was salivated, and suffered from cardiac oppression and difficulty of breathing; he fancied his chest was full of fluid, and afterward he expectorated some frothy mucus. The cardiac oppression lasted about ten minutes, but for two hours the patient continued to have a feeling of constriction at the pit of the stomach. During this time he suffered from lachrymation, running from the nose, gastralgia, and nausea; he vomited three times, and passed his urine involuntarily. The intestinal peristalsis became violent, and he had tenesmus. His eyes were fixed, and he could not recognize any one twenty centimetres (eight inches) distant. The pulse was quick and small, the sufferer being in a condition bordering on collapse. By means of internal and external stimulants the symptoms disappeared.—*The Lancet*, February 6, 1892, p. 329.

CORONILLA.

M. V. Poulet (*Bulletin Général de Thérapeutique,* 1891, No. 46, p. 481) gives the result of his studies. The tincture of the entire plant was used in daily dosage of from one to two and a half drachms, believing that it was valuable in paroxysmal tachycardia, in the painful phenomena of certain reflex cardiopathies, in the disorders occasioned by changes at the aortic orifice; it relieves the symptoms due to lesions of the mitral valve; that it cuts short, frequently in a remarkable manner, the attacks of cardiac or bronchial asthma, it increases the appetite; is a tonic so far as the alimentary canal and general system are concerned. It is superior to digitalis in that it does not have a cumulative action, is not a depressant, nor does it give rise to digestive disturbances. Its chief value seems to be in the nervous affections (erethism) of the heart, whether primary, or secondary to a general neurosis, particularly in cardiac disturbances due to excess in venery, tobacco, coffee, or alcohol.—*Amr. Jour. Med. Sci.*

NERVOUS SYMPTOMS FOLLOWING THE USE OF QUININE.

Dr. A. Erlenmeyer reports (*Centralbl. f. Nervenheilk*), a case of poisoning by quinine which seems to be of some interest. Previous to this writing the author had observed abolition of the reflexes in several patients who were taking large doses of quinine, but in the case under consideration the symptoms were of an intense reflex irritability. The patient, aged forty-two years, had taken at one dose 1,0 of the drug, on the following day 2,0, in broken doses, examination of the patellar reflex at this time, by tapping and so forth, brought on a series of general convulsions with violent contractions of the arms and the whole body. On leaving off the medicament for twenty-four hours the nervous excitability would entirely disappear.

DIETETIC TREATMENT OF CARDIAC DISEASE.

Hirschfeld (*Berl. klin. Woch.*, March 4th, 1892) says that in the corpulent the diminution of fat, along with diminished weight, is accompanied by a considerable loss in albumins. All cures for obesity consist in diminished nutrition. In spite of this, certain organs gain in working power, as is also illustrated by the hypertrophied sterno-mastoid muscles in phthisis. In ordinary people, as in the corpulent, the heart muscle under such conditions maintains, or even increases, its working power. In diminished nutrition the total amount of blood is lessened. On the other hand, by the absorption of dissolved food stuffs into the circulation more fluid has to be driven by the heart. Again, when food is taken there is an increased consumption of oxygen by the glands, etc., and therefore more blood has to be sent to the organs in question. Thus, with a lessened supply of food, the amount of work to be done by the heart is

diminished, and at the same time its working power is not affected. If a valvular defect arise after rheumatism the reserve power of the heart is called upon before compensation is established. A limitation of diet is here certainly correct. It is more difficult to decide upon the value of this limitation in disturbance of compensation. The undoubted value of the milk cure is in the author's opinion due to limited supply of food. Touching upon the subject of strengthening the heart by muscular activity, Hirschfeld points out that the latter should be increased but gradually, and that the Marienbad cure as usually practiced requires of the heart too great exertion in too short a time. This over-exertion may predispose to dilatation. —*Brit Med. Jour.*

SALICYLATED COLLODION FOR THE ITCH

This has been found exceedingly satisfactory, according to a report of A. S. Rauschenberg in the *Pharmaceutical Record.* The treatment in seven cases consisted in first ordering a hot alkaline bath, to remove all grease from the skin, and then to apply to each spot where the disease showed itself a coating of the N. F. salicylated collodion, i. e., the ordinary corn cure. Each night the patient was examined for new spots, which were carefully painted as well as all those places in which the covering had become injured. The cure is completed within ten days. The advantages of this treatment are: immediate cessation of pain (the first application causes transient smarting), simplicity and cleanliness.

CEREBELLAR TUMOR.

Dr. Howard publishes in the *Australian Medical Journal* the case of a patient who had been under his care suffering from cerebellar tumor. The patient was a woman of forty, who for six months before her confinement in December had suffered from headache, giddiness, and unsteadiness in walking. Her symptoms became aggravated after her confinement; she staggered in walking, being inclined to fall to the left side. She had severe headache, worse in the occipital region to to the right of the middle line. There was no actual paralysis, her knee-jerks were normal, and there was no change in the optic discs and fundi except some venous engorgement. Death took place suddenly, and at the necropsy a round tumor was found arising from the back of the inferior vermiform process of the cerebellum, and growing forward so as to fill all the front part of the fourth ventricle. The tumor was an inch and three-quarters long and an inch and a half broad, and in structure was a mixture of glioma and sarcoma.—*Lancet.*

NUCLEO-ALBUMINE IN THE URINE.

Dr. Obermayer, in a lecture given before the "Gessellschaft der Aertze," reviewed the different forms of albumin, among which mucus was formerly designated, generally as an albuminate. According to its reaction and behavior with acetic acid, it has been more recently classed as an uncrystalline body allied to the proteids, forming a group which is easily precipitated by acetic acid, whose members are mucine, nucleine, nucleo-albumine,etc. Mucine and nucleo-albumine have been frequently found in the urine, but nuclein is invariably absent. Obermayer asked himself if the presence of nucleo-albumine was the result of morbid changes in the kidneys. With this question before his mind he had examined six cases of leukæmia in Prof. Nothnagel's clinic, and found nucleo-albumine in each case. In thirty-two cases of icterus that he examined, nucleo-albumine was present; in other diseases where the kidneys were affected or irritated by the use of irritants, such as sublimate, naphthol, pyrogallol, etc., as well as diphtheria, where it was found in a very large quantity; in scarlatinal nephritis and other acute forms of morbus Brightii, none or scarcely a trace was to be found.

In cystitis it was also found in considerable quantity. These results raised the question of a morbid origin, which Obermayer has divided into vesicular and renal nucleo-albuminuria, but leaves it questionable whether the latter is hæmatogenous or inogenous. He considers the renal nucleo-albuminuria is the result of injury to the renal epithelia, and more particularly that of the medullary, which is of clinical importance and may be found to possess diagnostic method.

THE RECENT EPIDEMIC OF INFLUENZA IN BERLIN.

Renvers (*Deutche medicinische Wochenschrift*, Dec. 17, 1891) states that the first epidemic of influenza reached its height in Berlin at the end of December, 1889. Since January, 1890, the epidemic influenza has been absent from Berlin, though there was always the temptation to call every severe catarrh influenza. During 1890 and 1891, there seemed to be a special tendency to catarrhal affections throughout the city. At the end of October, 1891, the writer observed the first typical attack of influenza again. The epidemic has developed complications in persons troubled with heart and kidney affections, and the prognosis is grave in such cases. In young children there appears to be an early appearance of heart weakness. Lung complications are very frequent. Since November 7, there were twelve cases of inflammation of the lungs, four of typical croupous pneumonia, and four or five of catarrhal pneumonia. In these there is but little dullness, usually a rapid disappearance of the fever. The sputum is tenacious and expectorated only with the greatest difficulty. He thinks that true pneumonia rarely appears, but the influenza catarrh gives a starting-point for all sorts of secondary infections of the lung alveoli. Influenza can also cause death through capillary bronchitis. There were also severe nervous complications during the epidemic. In a great part the epidemic resembles that of former years. He believes that the influenza is both infectious and contagious.—*Univ. Med. Mag.*

RETINAL BLOODVESSELS.

Dr. James Musgrove gives an account in the last number of the *Journal of Anatomy and Physiology* of a method of preparing the retinal vessels for demonstration either with the naked eye or with the lantern. His observations were carried out on the eye of the ox, but his method is equally applicable to that of other animals or of man. In the case of the ox the injection can be made quite well after the eye has been removed from the orbit. As much as possible of orbital fat and tissue should be removed with the eye-ball, and the vessels are to be cut far away. The injection is made through the ophthalmic artery with a hand syringe, and the eye should be kept in hot water for half an hour before the injection is made. When the injection is completed the eye is allowed to cool for two or three hours to allow the gelatine in the injection to set. The entire retina is then removed by cutting through the cornea and iris and removing the lens and vitreous. The retina is then found hanging down from the optic disc, and its attachment there is divided with a knife. The entire retina may thus be freed and floated out on water, and it is then spread out, with considerable trouble it is true, on glass by means of a small camel-hair pencil. The specimen is then dehydrated and clarified in oil of cloves, after which balsam dissolved in benzol is spread over it, and another thin lantern slide used as a cover glass. In this way the retinal vessels can be clearly demonstrated, and Dr. Musgrove gives a short account of their distribution, in which he found a remarkable uniformity in the different retinæ examined.—*Lancet.*

AN UNUSUAL NEUROSIS.

An interesting case of an unusual neurosis has been recorded in a foreign contemporary. The patient was a teacher, intelligent, unmarried, aged 25, with no neurotic family history. Menstruation was regular in time, but protracted in duration, and always accompanied with pain. One day her left eye was injured by a broken violin string, and as the result of this it was noticed that reading readily caused annoyance. On examination no lesion of the eye could be detected. There was considerable headache. Soon afterwards it was observed that on excitement or emotion the left half of the face flushed and became warm, and in the course of two or three seconds the left side of the face and head became the seat of profuse perspiration; the left ear became purple, and from the auditory canal there flowed an aqueous discharge. A sense of fullness was also felt in the left nostril. At the same time the right side of the face became pale, dry, and cold. If the prorocation was intense, the left arm up to the elbow-joint became red, but without perspiration. The phenomena were aggravated during menstruation. Improvement took place as menstruation was regulated, and when the constipation, which was

troublesome was relieved. Iron and aloes were the means by which a cure was effected.—*Medical Press.*

FRONTAL HEADACHE AND IODIDE OF POTASH.

A heavy, dull headache, situated over the brow, and accompanied by languor, chilliness and a feeling of general discomfort, with a distaste for food, which sometimes approaches to nausea, can generally be completely removed by a two-grain dose of the potassic salt dissolved in half a wine glass of water, and this quietly sipped the whole quantity being taken in about ten minutes. In many cases the effect of these small doses has been simply wonderful. A person who, a quarter of an hour before, was feeling most miserable aud refused all food, wishing only for quietness, would now lake a good meal and resume his wonted cheerfulness. The rapidity with which the iodide acts in these cases constitutes its great advantage.—*Mass. Medical Journal.*

CONFUSION BETWEEN RODENT ULCER AND EPITHELIOMA.

In the meeting of the K. K. Gesellschaft der Aerzte in Vienna, November 13, 1891 (*Deutsche Mediz. Zeitung*, November 19), Adamkiewicz showed as healed a patient whom he had treated, apparently undeterred by the regrettable example set by Koch, by means of injections of a secret remedy. Four days after the injection healing began, and in about six weeks the whole surface was completely skinned over. As diseased foci were still to be found at the periphery, and as somewhat rapid skinning over of the centre of such ulcers may be attained by other means, the procedure did not meet with much commendation. But what was most striking was the want of distinction made by the speakers between "epithelioma" and "rodent ulcer." Both are epitheliomatous carcinomata, it is true; but the origin, microscopic appearances, course and prognosis of these affections are so entirely different, that the confusion of the two, or at least the want of appreciation by the leading speakers, Billroth and Kaposi, of their differences, tends to bear out Unna's statement that no new growth is so misunderstood in Germany as the ulcus rodens. The case in point was obviously a typical rodent ulcer of many years' standing attacking the neighborhood of the eye and spreading on to the lids. Kaposi had himself treated the case for years at intervals, whenever the patient would present himself, but he made no reference in his remarks to an ulcus rodens, and spoke only of hautkrebs and epitheliomata, some of which grew more quickly and deeply than others. Billroth spoke of the case as one of "flat epithelioma," "which is also distinguished because it commences in more advanced age (*im höheren alter*) as lupus senilis, or, again, as ulcus rodens."

Rodent ulcer is so common in England, and we have thus so many opportunities of observing it in all stages, that it seems to us difficult to understand why our German-speaking colleagues should continue to confuse two affections which are clinically so different as to their origin, course, duration, treatment and prognosis.

POLYURIA AND SCIATICA.

At a recent meeting of the Medical Society of the Paris Hospitals, Drs. Debove and Rémond announced certain phenomena which they had observed in their cases of sciatica. In the first case they found that polyuria was present, the amount of urine passed daily, varying from 2 to 4.25 litres.

Inquiry elicited the fact that the same thing had occurred three years before when the patient had suffered from an attack of sciatica.

This led to further investigation and three other sciatic patients were found in whom a like condition was present. In one of these cases azoturia was found in addition to the polyuria.

Dr. Mathieu, having heard of these facts from his confrères, was led to make investigations on his own account, aud he also found polyuria present in two patients suffering from sciatica.

Dr. Desnos thought he had found this condition present in other painful affections, as for example in hepatic colic.

ALBUMINOUS PERIOSTITIS.

Dr. Dzierzawski communicates to the Polish medical journal, the *Kronika Lekarska*, an article on the so-called "periostitis albuminosa" of Poncet, Terrier, and Lannelongue. He has been able to find, in addition to his one case, twenty-

seven cases reported in medical literature. It is an affection of the periosteum characterized by a clear, tenacious exudation, resembling the synovial fluid or the white of egg, and it is, of course, from this circumstance that the name has been given it. Some authors, as Nicaise, Riedinger, Albert, and Duplay, look upon it as a special pathological form; while others, as Schlange, Roser, Vollert, Garrè, and Oliver, are disposed to regard it merely as a variety of purulent periostitis. Dr. Dzierzawski's own view is that it is not a disease *sui generis*, but that it is comparable to those cases of contagious osteo-myelitis where a clear fluid exudation is formed owing to a low type of inflammation, or to tubercular cases, where there are infiltrations or cold abscesses. The small number of pus corpuscles can be explained, according to Schlange, by their deficient formation owing to the weakness of the inflammation, or, according to Farrè, by supposing a secondary liquefaction of these bodies by a serous exudation. Under some conditions the periosteum may give rise to exudation containing mucus, consequently there is no need to suppose that the pus corpuscles undergo mucous degeneration, and a better name for the affection under consideration would perhaps, according to the author, be "non-purulent osteo-periostitis."—*Lancet.*

CROSS PARALYSIS.

Dr. Porter showed a brain before the Sheffield Medico Chirurgical Society, from a patient who had been under his care at the infirmary with cross paralysis. There was a small tumor on the left half of the pons the nature of which had not then been investigated. The patient, a man aged 40, was admitted with right hemiplegia and paralysis of the right side of the face, and internal strabismus of the left eye. There was never any contraction of the pupils. No anæsthesia and no affection of the fifth. The knee-jerks were exaggerated on both sides, but especially so on the right, and ankle-clonus was very marked on the right foot. The speech was slurred and laterally the tongue inclined slightly to the right on protrusion. There was a family history of both cancer and tubercle. No syphilitic history. The diagnosis was lesion of the pons. The patient died comatose seven weeks after admission, or four months from the commencement of the disease.—*Lancet,* June 20th, 1891.

ANALGESIA AND ATROPHY OF THE TESTICLES IN LOCOMOTOR ATAXY.

Bitot and Sabrazès (*Rev. de Mèd.*, November 10, 1891) give details of 37 well-marked cases of locomotor ataxy, in 10 of which the testicles were hypo-algesic (twice only on one side), in 18 absolutely analgesic (once only on one side), and in 9 healthy. The affection was more pronounced when ataxia was present, and even existed in the absence of any local loss in common sensation. Parallel with it there was increasing trouble in the genital functions. There was no constant relation between the analgesia and the disappearance of the testicular reflex. In 5 cases there was atrophy of the testicles (once, perhaps, antecedent to the nervous disease), the organs being soft and flabby. In 4 of these 5 cases syphilis was excluded. Among many other cases of nervous disease, the authors only found testicular hypo-algesia in 3 cases, and anæsthesia in 5; and in 5 out of these 8 cases there was inco-ordination of movement and absent knee-jerks, and 2 others were examples of progressive general paralysis. This affection may also be present in chronic arsenical intoxication, and rarely in male hysteria. In old people the glands are shrunken, but there is no hypo-algesia. In 2 of the cases with analgesia and atrophy of the testicles the nerves were examined. The myelin did not take the stain well with osmic acid; and, although presenting moniliform enlargements, it was not broken up. As to the cause of the analgesia the idea of a peripheral neuritis suggested itself: but the authors say that histological *technique* is not advanced enough to reveal slight lesions in the nerves, and that perhaps the pathogeny should be sought in the spinal cord.—*Brit. Med. Jour.*

A CASE OF CONGENITAL TUBERCULOSIS.

Sabourand publishes the following case of congenital tuberculosis in *Mèdecine Moderne* of 29th October, 1891:—The mother was a patient in St. Antoine obstetric wards. The apices of both lungs were dull, and signs of softening were

heard over the left apex. The child, a girl, was born on the 5th of August, and was of normal weight and size. The mother made a good recovery, and was dismissed on the 15 August. The placenta had not been examined microscopically. When five days old the infant had a conjunctivitis, more serous than purulent, which disappeared under treatment with nitrate of silver. On the ninth day it seemed ill, and though feeding well had a little diarrhœa. Next day it became cynanotic, and fine râles were heard over both lungs. No convulsions nor other symptom preceded death, which occurred on the morning of the eleventh day. The liver and spleen only were examined *post-mortem*. The liver was normal in size, weight, and color, without peri-hepatitis. It was riddled with tubercles varying in size from 1 to 2 millimetres, and equally distributed throughout its entire thickness. The spleen was small, hard, contracted, with the capsule thickened, and was studded throughout with tubercles of various sizes, some as large as 1 centimetre in diameter.

Microscopic examination of the liver shows that there is no trace of normal lobulation, the cells being agglomerated between the tubercles. Some tubercles are as large as a lobule, and the centre of the former seems to coincide with that of the latter, the vein being sometimes recognizable. The histology is similar to that observed after experimental inoculation: the blood-vessels are primarily affected, the nuclei being most abundant round the arteries. The bacteriological examination of the liver showed multitudes of bacilli, chiefly intra-cellular. The stain used was Ehrlich's anilin gentian violet, with safrinin as a contrast stain. With the spleen, Ziehl's solution with nitric acid showed the bacilli to be present in great numbers.

The mother died two months after the birth of the child. The pulmonary conditions progressed rapidly, and meningeal symptoms with coma set in before death. *Post-mortem* examination showed no evidence of tubercle in the breast or sexual organs. The lungs were permeated with tubercle, but there was no cavity.

The questions as to the date of infection of the child and the mode of invasion are the most important. The *post-mortem* appearances of the liver are similar to those seen in congenital tuberculosis of the lower animals, and may be accounted for by the fact that during intra-uterine life the blood is, one may say, filtered through the liver. The age of the child at death and the advanced nature of the lesions show the infection to have been intra-uterine. The splenic condition shows the disease to have been a blood infection.

MEDICINE.

LEUCOCYTOSIS IN PNEUMONIA.

Dr. R. von Jaksch, in the *Centralbl. fur Klin. Med.*, draws attention to the fact that the prognosis in cases of croupous pneumonia in which leucocytosis does not appear is very unfavorable. He thinks that in these instances it would be advisable to give by the mouth or hypodermically either pilocarpine, antipyrine, or nuclein, all of which, according to Horbaczewski, increase the number of white blood-corpuscles. Dr. von Jaksch is fully convinced that pilocarpine in croupous pneumonia actually increases the number of white corpuscles when a condition of leucocytosis already exists. For instance, in a patient suffering from pneumonia of the right base the number of white corpuscles was increased 62.7 per cent. an hour after the hypodermic injection of 0.005 milligramme of hydrochlorate of pilocarpine. This sudden increase was not due to the ingestion of food, as the patient during the same time was kept without nourishment.—*Lancet.*

ELONGATION OF THE LIGAMENTUM PATELLÆ AS A FACTOR IN THE PRODUCTION OF CERTAIN KNEE TROUBLES.

Dr. Newton M. Shaffer concludes as follows on this subject:

1. Elongation of the ligamentum patellæ may produce weak, painful, and apparently inflamed knee joints.

2. Many obscure knee-joint troubles, as well as impaired or difficult locomotion, may be explained by this condition.

3. Elongation of the ligamentum patellæ may produce a disability very like that produced by ligamentous union after transverse fracture of the patella.

And, finally, elongation of the ligamentum patellæ may be, and very frequently is, produced by forcibly breaking up a fibrous anchylosis of the knee-joint.—*Medical Record,* Jan. 16, 1892.

BONY DEPOSITS IN THE SKIN.

White (*Birmingham Medical Journal*, November, 1891.) relates a remarkable case of this condition, and compares it with Mr. Hutchinson's, reported in the *Medical Times*, 1890.

The patient was badly scalded in a railway accident in 1842, the skin of his legs being almost entirely destroyed. The healing process occupied five years, the bony plates making their appearance at a much later period. Their development has been going on in the last twenty years, in the calf, in front of the knee, and at one time completely encircling the leg. Removal has been sometimes necessary on account of irritative dermatitis set up.

Mr. White holds that failure of nutrition is not a sufficient, if any, explanation of the condition. "It results from the simultaneous action of the processes of deposition and incorporation, the least soluble salts of the nutritive fluid being left by a particularly sluggish current to become subject to the selective activity of the connective tissue cell."

SPONTANEOUS CURE OF DETACHED RETINA.

Marchetti (*Rif. Med.* January 16th, 1892) reports the following case: A man, aged 55, observed during November, 1890, that the vision of his left eye was becoming dim. This dimness increased very rapidly, and in four days there was left only perception of light. Examination revealed extensive detachments of the temporal and frontal portions of the retina, and of a great part of the nasal portion. The detachment fluctuated in the lower portion with the ocular movements; in the other parts it was distended in folds. Tension was reduced, vitreous transparent, and disc normal. Vision was restricted to P. L., and perception of movements of the fingers in the temporal section of the field of vision only. Vision had been previously good, but each cornea had a central leucoma, the remains of inflammation many years previously. He was treated with pilocarpin injections and iodide of potassium, and advised rest in the horizontal posture. In February, 1891, having continued the treatment till then, the eye was in the same condition, when quite suddenly, on the 16th, he regained his sight. This followed, apparently, on a sudden rotation of his head towards the right side, the patient feeling immediately, as it were, a blow on his useless eye. Directly after this he found that he could see objects distinctly and without any difficulty, and eight days after he could read small type quite easily. In June, when he again presented himself for opthalmoscopic examination, there was a light grey streak corresponding to the detachment, but no displacement whatever remained. The field of vision was nearly normal, save for colors, and the acuity nearly as good as before, having regard to the existence of the old leucomata. The author is inclined to attribute the sudden cure to a rupture of the detached portion, with escape of the subjacent fluid. —*Brit. Med. Jour.*

SURGERY.

ANTISEPTIC MIXTURES.

Dr. A. Cavazzni has recently reported his experiments with mixtures of various antiseptics in the form of powders. His first observations were made in thirty cases of venereal buboes. He regards iodoform as one of our best remedies in these cases, but it has the disadvantage of not possessing marked antiseptic properties. To overcome this deficiency he added salicylic acid, which is powerfully disinfectant, but somewhat irritant. The irritation was, however, avoided by the addition of subnitrate of bismuth which is, moreover, slightly antiseptic. Finally, to increase the stimulant effect of this preparation in cases of atonic ulcers some camphor was added. After numerous trials the following formula was adopted:

Iodoform	55 parts.
Acid Salicylic	20 "
Bismuth Subnitr	20 "
Camphor	5 "

The ingredients are well rubbed together and form a pale yellowish, somewhat mealy powder, which produces slight, but transient irritation, when applied to fresh wounds. This mixture is an excellent disinfectant and stimulant in cases of bubo. Its disadvantage is that it encourages hæmorrhage from the granulations, but this may be avoided by discontinuing it every fifth of sixth day and replacing it by iodol. In persons with delicate skin it may also produce excoriations.— *Wiener Mediz Presse.*

ON THE RELATIVE VALUE OF PERINEAL AND SUPRAPUBIC LITHOTOMY.

Dr. Wilhelm T. Lindenbaum (Jaroslavl, Russia), in the course of the last nine years, has made 70 perineal lithotomies in children under 15 years of age, with 2 deaths; and 32 in adults, with 8 deaths. Besides, during 1890 he performed 10 suprapubic lithotomies in patients aged from 8 to 52, with 1 death (the fatal case referred to. a man of 52, with pulmonary tuberculosis and fatty heart). The high operation was conducted after the following rule: 1. All instruments were sterilized; 2. Colpeurynter was introduced into the rectum; 3. The bladder was filled up with 250 Cub. Cm. of a salicylate solution; 4. Drainage was inserted (no vesical sutures being employed); 5. The patient was kept on his abdomen for from 8 to 10 first days; 6. The dressing was changed once daily. The urine began to flow through the urethra, on an average, on the 20th day, the wound soundly healing on the 30th. As far as young children are concerned, suturing the bladder is thought to be very difficult, and on the other hand, quite superfluous, since a healthy urine does not irritate the wound. The author's general corollaries are as follows: 1. Perineal lithotomy in early childhood represents a safe operation and gives excellent results. A relatively enormous percentage of deaths in old age can be explained by the coexistence of grave complications about viscera (especially kidneys). 2. Suprapubic lithotomy does not offer any important advantages over the perineal operation. The mortality remains yet very high, even in children. 3. Still, speaking generally, in the presence of stones, measuring above 2 Cm. in diameter, the high section should be preferred, but in cases of smaller calculi perineal lithotomy should be performed.—*Meditzinskoië Obozrenië*, No. 2, 1891, p. 133.

"MOOSE-PAPPE" AS A SURGICAL DRESSING.

Moose-pappe as an absorbent aseptic dressing, says Dr. C. G. Campbell, of Saddleworth, England, is not as well known as its merits deserve. Moose-pappe (sphagnum, or turf-moss) has great absorbent powers, taking up twenty-one times its original weight, and is decidedly the cheapest absorbent in market. When placed in contact with a liquid, moose-pappe seizes the liquid; its bulk becomes rapidly and enormously increased. The absorbed liquid does not lie on the surface or between the fibres (as is the case with absorbent cotton and wood-wool), but is shut up within the capillary cells of the moss. Thus, though it is full of liquid, it does not feel wet, and, though it may be full of pus, it appears clean. Where with an ordinary absorbent, daily dressings are required, the busy practitioner may safely leave his moose-pappe dressing two or even three days untouched, and will find, when he removes it, not a stink and a gush up of sealed up pus, but a clean wound and no smell.

As a dry dressing the moose-pappe of Dr. Rodolphi is, perhaps, the most convenient. It can be rapidly crumbled on thin gauze (which is then loosely folded over it). Moose-pappe (Hagedorn), prepared in this way, makes a beautiful, soft, dry dressing for amputations or large wounds. As a moist compress for ulcerating surfaces, moose-pappe (Hagedorn), lightly dipped in a boracic or other antiseptic fluid, makes an ideal dressing, whilst, as a padding for splints, particularly in cases of compound fracture, or fracture complicated with flesh-wounds, moose-pappe will be found most satisfactory.—*The Medical Chronicle*, February, 1892, p. 292 *et seq.*

A NEW AURAL RETRACTOR

Barth (*Arch. of Otol.*, xx, 1) describes a new retractor for spreading the divided soft parts during the operation of chiseling into the mastoid process. It consists of two bars, each provided with three sharp-pointed hooks; these bars are connected by two rods and a screw in such manner that when approximated the hooks form a single line. After having divided the soft parts, including the periosteum, and having separated the latter from the bone, the hooks of the retractor are applied so that the points touch the bone at the spot where we wish to continue to operate. Then they are separated; the points of the hook grasp the deeper soft parts, while the arms from which the hooks spring separate the more superficial soft parts and especially the divided integument, and push the auricle forward. When completely separated, the space included between the two arms presents a clear field for operation.

OBSTETRICS.

THE BLOOD IN PUERPERAL SEPSIS.

Ott reports from the clinic of Von Jaksch in Prague (*Prager medicinische Wochenschrift*, 1892, No. 14) a case of puerperal sepsis in which the examination of the blood afforded information of interest. The patient was probably infected by a midwife who attended her; two days after labor she had a severe chill, followed by fever. The midwife who cared for her had a felon upon the middle finger of her right hand where the skin had been broken. During the patient's illness her urine was examined and found to contain albumin and an abundance of aceton and urobilin. An examination of the blood showed 3,470,000 red to 15,320 white corpuscles, a ratio of 1 to 220. The percentage of hæmoglobin was $8\frac{4}{10}$. An examination of the blood stained by Gram's method showed the presence of numerous cocci in groups. Septic panophthalmitis developed on both sides. An examination of the colostrum from the breast showed the presence of cocci. The patient died about two weeks after labor, and a post-mortem revealed the lesions common in puerperal pyæmia. The cocci present in the blood, and also the condition of leucocytosis which was present, render the report of the case of unusual interest.—*Amer. Jour. Med. So.*

PRESENTATION REPEATEDLY CHANGED BEFORE AND DURING LABOR.

Gallois (*Journ. des Sages-Femmes*, April 1st, 1892) reports the following case:—The patient was an imbecile, aged 24, who had borne a dead child four years previously. She was admitted into a lying-in hospital on August 4th, when about seven months pregnant. The pelvis was narrow, not flat. The child lay transversely in the pelvis, the right shoulder tending to present. The breech was easily brought down but the fœtus quickly returned to its faulty position. An attempt was made to keep the breech down with Pinard's Belt, Gallois intending to induce labor directly the desired presentation was made sure: but the belt chafed the skin, and the feeble-minded patient would not tolerate systematic precautions of this kind. On 12th, in the morning, labor came on. A foot could be felt through the membranes, with the breech above it not engaged. In the evening the pains were rapid, the membranes intact; the patient had been left alone for a long time lest the waters should be ruptured too soon. On examination, the face was found presenting. In the small hours the waters broke, the fœtal heart sounds became weak: two hours later the brow presented. The child was delivered asphyxiated. It recovered, and so did the mother. The deformities found on the fœtal head were very marked, and intermediate between those seen in brow and those observed in face presentations. The caput succedaneum occupied the forehead but hardly reached the eyelids. The cheeks were spared, the lips tumefied: there was right facial paralysis.—*Brit. Med. Jour.*

HEMICHOREA IN PREGNANCY.

Dr. Cameron in the "*Montreal Medical Journal*," January, 1892, writes, that, as in the non-pregnant, peripheral lesions may cause choreic movements, which subside when the irritating part is exercised; so in pregnant women peripheral irritation may be propagated from the uterus to the central organs and may keep up choreic movements till the cause of irritation is removed. This is well exemplified in the following case: An anæmic, neurotic patient, subject to hysterical fits, bearing family rapidly, with a lacerated crevix and a tender retroflexed uterus, developed chorea of the right side of the body in the month of pregnancy; in a few days the left side became involved while the right side began to improve. By appropriate mechanical treatment the retroflexion was corrected, and the chorea disappeared in little more than a week.

GYNECOLOGY.

A CASE OF PRECOCIOUS MENSTRUATION.

Jakubovitch (*Vratch*, No. 9, p. 214, 1892 *Rev. Gener. de Clin. et de Therap.*, April 20, 1892) reports the case of a girl who menstruated shortly after the age of 10 years. Her period lasts for 3 or 4 days, and the act occurs several times in the course of the year. Every menstrual period is preceded by nervous disturbances, such as headache, excitement, etc. The external genital organs are well developed;

the mammary gland are of the size of an egg, and at the time of menstruation they swell up and secrete milk. Apropos of this the author, in reviewing the literature of the subject, finds the records of only 35 cases analogous to the present one. Precocious menstruation is, therefore, rare, and adds, that the prognosis is favorable, although the hæmorrhages may give rise to the production of anaemia and chlorosis. The observer advises, if the loss of blood be considerable, the administration of hydrastis canadensis and ergot.

TREATMENT OF FIBROID TUMORS OF THE UTERUS BY INJECTION OF ERGOT.

J. Schneck (*Medical Age*, April, 1892) gives the histories of three cases of uterine fibroids treated by injections of ergot into the substance of the tumors, with satisfactory results, and states that several other cases are still under observation. The preparation of ergot used is a good fluid extract, in half drachm doses, and the instrument employed is the hypodermic syringe, with a long needle; a small aspirator having been used in a few instances. It is desirable to make the injection into the centre of the tumor as nearly as possible. No evil effects have been noticed after the treatment. In a few instances a chill, followed by moderate fever, occurred, but these symptoms disappeared after a few hours. In one case reported there was an intramural fibroid encroaching upon the cervix, and about as large as an orange, in a patient 42 years old. Profuse menorrhagia had existed for five months and ergot and other astringents by the mouth had failed to control it. Injections of half drachm doses of ergot into the tumor daily for eighteen days, and every second or third day afterward for the following month caused the bleeding to cease. Menstruation is regular but there is no inter-menstrual bleeding and the patient feels well, although there is no note as to the condition of the fibroid.

Another patient, of about the same age as the first case, had profuse menorrhagia following a miscarriage, for the control of which ergot was given by the mouth, with no success. An examination revealed the presence of a large fibroid in the right lateral wall of the uterus. By use of an aspirator needle the injections of ergot were given once a week for nearly five months. The hæmorrhage was controlled during this entire period, and at the end of this time the tumor was found to be extruded into the uterine cavity, attached to a thick pedicle, and was removed by the ecraseur. The tumor was so large that the wire could not surround it, and several portions had to be cut away first. There was but slight bleeding during its removal, probably due to the action of the ergot diminishing its vascularity. The substance of the tumor was soft and friable, and probably it would have broken down and liquefied in a short time. The third case was one of fibroid tumor in the posterior wall of the womb, which had made such traction upon the fundus as to cause inversion of that organ with procidentia. The injections were practised once a week for two months, at the end of this time the tumor began to suppurate and discharge freely. After thoroughly disinfecting the parts, the uterus was replaced and kept in position by a pessary.—*Univ. Med. Mag.*

CANCER OF VAGINA CAUSED BY PESSARY.

Meyer (*Zeitschr. f. Geburtsh.*, vol. xxii, 1891, part 1) describes the case of a woman who suffered from primary cancer of the vagina, evidently caused by the irritation of a pessary which had been worn for a year without change or cleansing. The diagnosis was confirmed by excision of the affected part and vaginal extirpation of the uterus, after which the diseased tissue could be examined under the microscope.—*Brit. Med. Jour.*

PEDIATRICS.

A REPORT OF 392 CASES OF INTUBATION, AND 139 CASES OF TRACHEOTOMY DONE AT THE BOSTON CITY HOSPITAL.

Prescott and Goldthwait (*Boston Med. and Surg. Journ.*, 1891, cxxv., 694.) give the following statistics: Three hundred and ninety-two cases of intubation and 139 cases of tracheotomy have been reported, with a mortality-rate of 79-59 per cent. in the former, 88-5 per cent. in the latter; 2,815 cases of intubation and 22,941 cases of tracheotomy have been collected and analyzed, showing comparatively no difference in the mortality-rate

of the two operations. The results depend more upon the nature of the epidemic than upon the operation. With intubation the results depend more upon the skill and experience of the operator than with tracheotomy.

Thirty-seven cases were seen at least a year and half after recovery from intubation, with perfect voice, and with nothing that would indicate any ulceration from pressure of the tube.

HYSTERIA IN CHILDREN.

Jolly (*Deutche med, Zeit.*, April 4th, 1892) states that he has seen a considerable number of cases of hysteria in children which might give rise to difficulty in diagnosis. He has frequently met with persistent localized pain with convulsive phenomena, and also with inability to use an extremity, combined sometimes with distinct paralysis and anæsthesia, especially in children who have recently had acute infectious diseases. The paraplegic form preponderates, but occasionally monoplegia and hemiplegia may be observed. He has seen hemianæsthesia after influenza. Tremor was a common symptom in cases having a traumatic origin. He mentions also laryngeal disorders, and various affections of speech and hearing; in particular, stammering and more or less prolonged loss of speech, conditions which might be cured by a brief application of the faradic current. Deafness and amblyopia might also be observed. In cases in which hysterical fits of laughing or crying are followed by convulsive movements of the extremities Jolly recommends isolation, with cold douches to the face, or a somewhat painful faradic current. He relates one severe case commencing at the age of 9, in which the girl gradually grew worse, and indulged in foul and blasphemous language; at the age of 12 the evil spirit was exorcised by a thorough purging. In other cases with severe symptoms he has found the cold pack useful, or the syringing of the face with water; for the latter purpose a siphon of aërated water may be used.—*Brit. Med. Jour.*

HYGIENE.

MILK EPIDEMIC OF TYPHOID.

Dr. F. M. Williams, medical officer of health for Plymouth, has been good enough to give us particulars of the result of his inquiry into the occurence of enteric fever in connection with the milk supply for a portion of the town. Attention was first directed by the notification of three cases of enteric fever during two days in the same neighborhood, and the discovery that the households had a common milk snpply. The dairy which furnished the milk obtained it from a farm in the Plympton district, which is non-scheduled and in which the Compulsory Notification Act isnot adopted. This farm, which contains about one hundred cows, was visited, and the persons there employed stated that neither they nor their children had, during the last few months, suffered from illness or diarrhœa. The well, the cover of which is said to be leaky, was within some forty feet of the privy cess-pit, but examination by the chemical analyst gave negative results. Two other cases were shortly afterwards reported from the same milk supply, and Dr. Williams eventually ascertained that there had been a death from enteric fever on the farm some twenty days previous to his visit, the deceased being a grandchild of the caretaker. The medical man whe had attended the case confirmed the correctness of this statement, and added that there was another case of typhoid fever at that time, the patient being actually ill at the time of Dr. Williams' first visit. In conjunction with the medical officer of health for Plympton, steps were taken at once, the cows were all removed to another farm, the farm being closed as a dairy farm; the pump from the well was dismantled, the well closed, and the patient removed to hospital. Seven other cases having the same milk supply have been notified within a fortnight of the first cases not including two that have been notified since closing the farm. The total number of cases is thus twelve. One case has terminated fatally—a young man who was ordered by his medical attendant to live on a milk diet for some ailment, and who was one of the earlier cases reported.

The remainder of the cases are doing well, and it is hoped that there will be no more fatalities. It is stated that there was a severe case of enteric fever at the same farm some twelve months since, but no information as to the disposal of the excreta can be obtained, as the family had left the neighborhood. Dr. Williams is strongly of opinion, based on some years of experience of health work in rural districts, that

this is the cause of the present outbreak. As to the means of propagating the disease at the farm, he points out that the man and his wife were both engaged in the dairy work milking cows, etc., and nursing the sick child. The cesspit contained typhoid excreta, and probably polluted the well, although chemical analysis gave no proof of pollution. Two families have suffered severely, three members in one family and two in another. Several other members of this latter family suffered for a few days from diarrhœa, fever, and *malaise*. Several hotels were supplied with milk from the same farm, so that there might have been visitors who had contracted the disease at Plymouth, and not developed it until their return to their homes or elsewhere.—*Brit. Med. Jour.*

MEDICAL CHEMISTRY.

A STABLE SOLUTION OF SODIUM SALICLATE.

Solution of sodium salicylate for ready dispensing purposes very soon darkens in color, as every one knows, being due to the alkaline nature of the solution. To obviate this trouble, M. Rucker (*Zeit. O. Apoth. Ver.*) recommends the addition of a little salicylic acid, in the proportion of, say, 1 to 1000 for the sodium salt used, so as to insure a slightly acid reaction. To prepare a stable 10-per cent by weight solution direct from the acid, it requires 100 grams of salicylic acid, 61 grams of sodium bicarbonate and 1,095 grams of distilled water, the sodium salicylate formed representing approximately 122 grams. Cold water should alone be employed and too violent a reaction be avoided, while the salicylic acid must be slightly in excess. To further insure stability, filter through absorbent cotton or glass wool.

EXTRACTS OF ANIMAL TISSUES.

Extracts of animal tissues for hypodermic purposes, an extension in therapy of Brown-Sequard's spermatic treatment, are prepared by d'Arsonval by digesting for 24 hours the glands or other parts of the animal (such as pancreas, spleen, brain, muscles, etc.) with three times the weight of glycerin, at a temperature of 28°C. To this is added three times the weight of the glycerin of recently boiled, but cooled, water. This extract, containing 25 per cent of glycerin, is filtered and sterilized by exposing for one hour to carbonic acid gas under a pressure of 50 atmospheres, at a slightly raised temperature.

NEWS AND MISCELLANY.

SYPHILIS AMONG THE ANCIENT EGYPTIANS.

Proksch (*Archives F. Dermatologie U. Syphilis*, June 20, 1891) discusses the probable existence of syphilis among the ancient Egyptians. In studying a papyrus containing instructions about the management of a disease known to them as "uxedu," he has identified syphilis. The papyrus gives the treatment for uxedu in the anus, in suppurating wounds, in the mouth, in the eyes, in the bones, in tumors of the head, in the body, in pustules, etc., thus giving an almost complete history of the various situations in which syphilis may manifest itself. The author concludes that the uxedu of the ancient Egyptians is our syphilis.

THE OWNERSHIP OF AMPUTATED LIMBS.

A singular case has recently been tried before His Honor JudgeJones in the Bolton County-court. The plaintiff, Ellis Housley, sued the junior house surgeon at the Bolton Infirmary for £10, the value of one of the arms of his son, who had been hurt at His work. The limb was amputated at the infirmary, and after the operation the patient asked for the arm, but the house surgeon refused to allow him to take it away. A day or two later the boy died, and the father again demanded his son's arm along with the body for burial. It was argued for the plaintiff that he had a right to the limb, whilst for the defendant that there was no cause of action. His Honor said the plaintiff had no property in his son or his son's body, and even a guardian was only a guardian during lifetime and not of the dead body, and there was no obligation to bury. After further argument the solicitor for the plaintiff stated that if his Honor was against him on the common law, he could go no further, and there was a verdict for the defendant, with costs.—*Lancet.*

ARISTOL Antiseptic: Cicatrisant.

EUROPHEN Iodoform Substitute: Antisyphilitic.

SULFONAL-BAYER Hypnotic: Sedative.

PHENACETINE-BAYER Antipyretic: Analgesic.

PHENACETINE-BAYER is a true and distinct organic derivative. It is indicated in influenza (*la grippe*); in all fevers, with or without pain; in rheumatism and neuralgia; and in phthisis and pertussis. It acts promptly and is both safe and effective. Supplied in ounces, tablets and pills.

EUROPHEN, as a substitute for iodoform, is winning an enviable place in therapeutics. It has a special value in specific lesions, while as a surgical dressing in ulcerations, open wounds, and septic conditions of the cavities, it has given excellent results. Supplied in ounces.

SULFONAL-BAYER is indicated in all the insomnias and in the cerebral disturbances of insanity. It is a pure hypnotic, a safe and effective remedy, and it does not give rise to a drug habit. For the correct method of administration *see pamphlet*. Supplied in ounces, tablets and pills.

ARISTOL is widely esteemed by physicians for the excellent results it has given in the treatment of all external traumatisms; in cavital lesions, and in many of the dermatoses. As a surgical application, it is safe, inodorous and non-toxic. Supplied in ounces.

EUROPHEN-ARISTOL, a preparation consisting of equal parts of each medicament, is also supplied in ounces.

DESCRIPTIVE PAMPHLETS FORWARDED ON APPLICATION.

W. H. Schieffelin & Co., New York.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{50}$ gr.), Atropiæ Sulph. ($\frac{1}{200}$ gr.), Codeia ($\frac{1}{25}$ gr.), Antimony Tart. $\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis. fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{50}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonial from well-known clergymen. lawyers and business men, we prefer to leave them to the unbiased judgment of th profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that th applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double, boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

38 Maiden Lane, **New York City.**

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL & NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

Clinical Lectures.

THE LIMITS OF THE ART OF HEALING.*

By PROF. H. NOTHNAGEL,
VIENNA, AUSTRIA.

Honored Assemblage:—Death, disease, and bodily sickness of many kinds—this is the inheritance of suffering mankind. The powerful desire for life, the striving towards a painless existence, and the intense longing for health stand in opposition. To the existence of these two opposing facts, the art of healing owes its origin.

Mankind has become submissive to the inevitable existence of death itself. No one to-day, thinks of exacting such a requirement of medicine as an immunity from death. To be sure, why we must die at all, why even in the most healthy subjects the mechanism of our organism must cease its activity after eighty or perhaps a hundred years of work, these are questions which science can only answer very unsatisfactorily. Processes of material changes of any kind, either in the cells or organs, causing a weakening of their functions which are necessary for the maintenance of life, these are the causes. But the true "how" and the final "why" of these destroying processes still await explanation.

Standing, as we do, powerless before death, that unchangeable law of nature, the desire to prolong the life of each individual to its greatest possible limit, is easily understood. That disease shall not prematurely end life, that those disturbances connected with or following diseases shall be annulled or mitigated, these are the requirements which are demanded of medicine.

"The great and small world studies it through and through, only in the end to let the outcome be as god wills it," was the Mephistophelic ridicule regarding the real capabilities of medicine. The term "ignoramus" can be applied to the foremost scientist of to-day, as he stands before the most recent riddles of the human life—riddles, indeed, that form so large a component of the questions of theoretical medicine. But thousands of varied forms of misery are present with us, and in the hour of danger the sick call for help, and the suffering crave for relief from pain.

How far, in its practical application, does the science of medicine fulfil the foregoing requirements?

Where are its limits, and by what are these limits determined?

What is its outlook for further growth and usefulness?

The fact, that the practical art of healing has made great advances during the last century, and more especially during the latter half of the century, needs no elucidation. The rebuilding of pharmacology, the brilliant advances in ophthalmology, the remodelling of laryngology, and the astounding growth of operative surgery and gynæcology—in the field of internal medicine, the introduction of a large number of efficient medicinial substances, and of physical curative methods, and further the recognition of the value of physiological, dietetic, and hygienic factors of the most varied kind—all these have been factors in making this a noteworthy epoch. Then, the immortal discovery of Lister, and Pasteur's discovery of the curability of the dreaded hydrophobia, and not a year since the contributions of Koch that have awakened the

*Delivered before the Society of Natural Scientists and Physicians, at Halle, Germany; translated from the author's MS., as published in the *Wiener Med. Presse.*

highest and most intense enthusiasm, all these facts give additional importance to the question: where are the limits of the art of healing? We do well indeed to always strive towards a greater and always greater enlargement of these limits, and to hope for continued growth. It is a duty to strive towards such an end. But for the investigator, it is necessary for him to only see facts, and be uninfluenced by sentiment, and then, after quiet consideration to sum up not only the attained, but also the attainable.

"To be sick, is life under altered conditions," is the definition of the great reformer in medicine, our master and leader, Virchow.

What then, is healing?—To effect pathological changes in the organism—be these of a chemical or physical nature—in such a manner, that they are brought to a standstill, the changed tissue rendered histologically normal, and the altered functions rendered physiologically normal; to restore the proper relations between the tissues; to bring about a healthy condition of all the functions of the entire organic system —this is healing.

In what measure is the art of healing capable of fulfilling these requirements? If we endeavor to answer this question with the facts at hand, we find that the short hour given us for this lecture will only allow the answer to be a very fragmentary one. Yet this even will be sufficient for us to formulate some conclusions.

As paradigm we will let serve a condition which belongs to the most frequent occurrences—interruptions of continuity by external violence, either accidental or operatively designed. These are, as every one knows, curable. But the limits of the art in this case consist in the greatest technical skill in the apposition of the divided surfaces, and the keeping away of anything that would be likely to act harmfully upon the process of healing; but upon the process of healing itself—upon the organic reunion of the divided surfaces—all these precautions have no influence. The exudation of plasmatic lymph, the processes of growth and regeneration in the cells of the injured tissues—all these occur uninfluenced by us. We are astonished, and justly astonished, at the gigantic advance of operative surgery since Lister's introduction of the principles of antisepsis, and we may well bless the name of the man who has rendered it possible to save the lives of countless sufferers, by operative treatment, and to restore them to health. Yet, we must clearly understand that this advance only consists in the fact that by means of the protection afforded by antisepsis, allowable surgical procedures can be maintained in a condition which renders healing possible. But the healing itself occurs by means of processes that are beyond our control. Naturally the extraordinary practical value of the improved operative methods, which our surgeons have discovered, cannot be here taken into consideration, and for the patient while this is of vast importance, it is not so when viewing the matter from a scientific and logical standpoint. It must be understood that *healing* in the sense that our art controls by antisepsis the organic processes, is not affected even by the gigantic practical advances made in consequence of its application. We can cure, or cause the healing, of an ulcer or abscess no more to-day than we could formerly. Excision, or opening, of such is not synonymous with true healing. As it is with the superficial interruption of continuity by force (operations), so it is with internal processes under similar conditions. In ulcerations of the stomach or intestines we can influence healing in so far as to remove the causes of danger, but we do not restore the lost tissue.

In the rupture of a blood-vessel or the injury of cerebral substance, it is, of course, necessary by means of suitable methods to check the congestion in the brain, but none of our methods will remove the clot, or reunite the divided nerve substance.

Let us choose another very common process—inflammation. The long series of clinical pictures, now acute and now chronic, which occur in the most varied organs and tissues, and are all classed under the head of "inflammations" because analogous pathological processes and tissue changes exist in all and can heal, as daily experience teaches us—the acute processes frequently, the chronic more rarely. What part does therapeutics play in this healing?

In acute inflammatory processes—as our knowledge of to-day teaches us—there is no internal medicament of direct value; only indirectly in special cases can such remedy be of value, as for example, digitalis in pericarditis and myocarditis; or symptom-

atically, as the majority of remedies in acute catarrhs. Our therapeutic possibilities consist in very ancient possessions of medical science, which for centuries were used to excess, then in part completely abandoned, and at the present used with varying frequency. Rest, cold and local blood-letting form the ground-work of a a treatment for acute inflammations, which under certain circumstances is helpful. But how frequently is such treatment worthless; how often not applicable! Think only of all the deep inflammations, the inflammations of the mucous membranes; think only of all the cases where the process occurs with great intensity independent of specific forms, such as the tuberculous or the pneumonic. In these even we are far from having satisfactory proofs that the procedures referred to, even in cases where under their application the inflammatory symptoms subside, have any direct influence upon the pathological processes of inflammation themselves. True it would seem so, but the fact has been in no way satisfactorily elucidated.

As it is with the acute, so it is also with the chronic inflammatory processes. We may be able to influence recovery in certain favorably located forms—such as chronic inflammatory exudation in a joint, inflammatory thickening of a muscle, or perineuritic swelling of a reachable nerve, by massage, gymnastics, electricity, hydrotherapy, various baths, and counter-irritation; these are our aids. But of all these it can only be said that they "excite absorption." We possess no drug that effects a cure by directly influencing the organic processes incident to such a cure. This must not be regarded as a mere "dialectic difference," for to the patient it is entirely immaterial whether the massage or counter-irritation have acted directly or indirectly, so long as he is relieved from his long-standing perineuritis. But how is it with the application of similar remedies in neuritis of the trigeminus or optic nerve? Cure, in the true sense of of the word, can only occur in a case of perineuritis when we are able to effect a restoration of the histological changes of the nerves which have taken place. The same must be said of chronic inflammations of the mucous membranes, and parenchyma of the organs. In the most favorable cases, we are in a position by means of baths and "cures," dietetic and general hygienic regimen, or well as certain pharmaceutical preparations to influence certain symptoms, as to remove the product of the disease; yet the process of the disease in itself we do not influence.

But why should I tax your patience with the presentation of an endless list of unities? Why go into a description of the processes of degeneration and atrophies as they are met with in the different tissues and organs and give rise to the most varied clinical features; why enter into a description of the many diseases of the blood, and diseases accompanied by tissue change, or discuss the vast array of the various disturbances, either anatomical or functional, of the nervous system? Why discuss the thankless efforts for the cure of foreign growths (I do not mean excision, but "cure," in the sense defined above), which at present offers as good chances for ultimate success, as does the bottom of the Kamtschatka River for raising the date palm? In every instance, so soon as we come to regard the matter in its true inwardness, we are confronted by similar evidence, and arrive at the same results which our reasoning led us to in discussing interruptions of continuity and inflammatory processes.

Only one group of diseases can hold our attention for a moment longer, since great interest is linked with it. I refer to the group of acute and chronic infectious diseases.

Typhoid fever, scarlet fever, measles, and the vast list of morbid diseases of this group, and even sepsis can be cured. Far am I from denying that the art of medicine can aid most materially in influencing a favorable result in these cases, both by combatting the dangerous symptoms, as well as by means of general hygienic methods and dietery precautions. But is our art in a position to directly influence the process of the disease and so effect a cure? Our knowledge is so humiliatingly small that out of this enormous list of diseases we can only truthfully answer yes to this question in regard to two or three; these are in malaria, syphilis, and perhaps acute rheumatic polyarthritis, or perhaps even in these cases would we not do better by tempering our answer with the reservation that it at least *seems* to be a fact? It would almost seem so to me, as

the course of malaria, even after two hundred years of the pride of practical medicine would show. Then, in acute articular rheumatism, of its true being we know nothing, and while the salicylic acid treatment indeed causes a disappearance of the fever and articular affection, yet it has no influence upon the danger of subsequent endocarditis and its dreaded sequella, valvular diseases. And so, in all other infectious diseases—so soon as they have become well developed we cannot even to-day produce a cure in the truly scientific acceptation of the term. Wherever we may turn, we are confronted with apparently impassible barriers forming the limits of our art.

Let us endeavor, from the confusing mass of unities, to deduct some general conclusions regarding the limits of healing and curability.

Healing or cure is only possible so long as a disease is still in its course; so soon as it has reached a definite end, cure is no longer possible. There remain changes, atrophies, hypertrophies and other sequellæ of varied natures. In the commonest cases these changes are unaffected by therapeutics or regeneration although they may perchance be amenable to mechanical methods or the knife of the surgeon. An acute pleuritis is curable; the results left by it in the form of pleuritic adhesions cannot be cured. Acute endocarditis may disappear, but the valvular insufficiency caused by it cannot be cured. Anomalies in change of substance which lead to the formation of renal gravel, may be checked at the outset, but the formed stone can only be removed by the surgeon. An ulcer at the cardia of the stomach can heal, but the cicatrix left and causing stenosis, can at best only be excised.

The possibilities of therapeutic influence are in many cases determined by the location of the disease. An aneurism if situated at an artery of the extremities can be rendered harmless, but will cause fatal hæmorrhage if located in the aorta or arteria basilaris cerebri. An abnormal development of fat can be checked if it is confined to the superficial parts of the body, but it will finally end in death if the heart muscles become involved.

Of almost equal importance in the question of curability is the nature of the occurrence of the disease; whether its cause develops suddenly or gradually, with great intensity or not. The same amount of arsenic that under ordinary circumstances would be unfailingly fatal, is well tolerated by the accustomed arsenic eater, cholera or epidemic cerebro-spinal meningitis may attack two similarly constituted individuals; in the one causing death after a rapid and severe course, and in the other ending in recovery after a comparatively slight illness.

A disease becomes incurable when its causes continue without interruption.

Malaria will in the end most certainly cause death if the infected person does not leave the poisonous swamp-lands that constitute his home.

Bronchial catarrh remains stationary, and will finally end in causing a disease of the parenchyma, a disease of the lungs, if the patient remains under the influence of the possibly dust-laden atmosphere.

In similar suddenness and intensity of a disease cause, and by similar extent of the local development, the individual power of resistance, or especial constitution of the subject is of great weight. The same inflammation of the lungs, which a strong man thirty-years old, can live through, will end fatally in an aged subject, a heavy drinker, or one who has been enfeebled by a dissolute life or long previous illness.

Finally, *crimen non est artis sed aegrote.* With this sentence a long series of cases must be characterized, in which every medical or scientific aid is unavailing, while theoretically of little use to us in answering our question yet in actual fact they have considerable weight. Under the most favorable conditions the most efficient methods fail in effecting a cure, either because he does not or cannot conform to them. The most active treatment will not relieve the smoker of his pharyngeal catarrh so long as he continues to smoke. In this respect we are forcibly reminded of the nervousness and neurasthenia so common in our times. Lack of fore-sight or will-power in such cases prevent frequent possible cures; often to be sure, also, the power of external influences, which keep the unfortunate subject so long under the ban of circumstances until every therapeutic endeavor comes too late to be of any value except as a passing relief, but cure can no longer be effected.

Any ailment that does not fall under one of these categories is, in principle at

least, curable. The actual cure of such is the question of the times, in our minds. As remarkable as such a statement may appear at the present condition of our capabilities, we see no reason why the true curability of malignant growths should always be an impossibility.

* * *

The following we must now acknowledge is as an undeniable fact: the actual healing or cure, the restoration to a normal condition of function and tissues, changed either chemically or physically by diseases, can only be effected by living processes in the organism. Now, the answer to our question regarding the limits of our art, is dependent upon the extent to which it is, or will be, able to influence these processes, and to determine whether or not it may extend the limits of its capabilities. And if it is shown that it can not do this or at best only in a very limited manner, then the second question comes, whether its usefulness is here at an end, or whether other possibilities are not open to it, constituting a high end for it to strive for.

With certainty can we say, that certain pathological changes stand as insurmountable barriers before even the most advanced science. Never will we be able by means of our art to restore lost cells or cause the reunion of what has been divided, never will we be able to directly influence the ganglia cells and train of associations that plays the real part in the manifestations of hallucinations.

True, by means of the exhibition of certain substance we are able to effect changes in the protoplasm of certain cells thus giving rise to certain physiological effects, although how this is accomplished is not understood. Many of the alkaloids act in this way: alcohol, ether, chloroform, bromine, curare, digitalis, and many other drugs act directly upon the substance of certain groups of ganglia-cells, as well as nerve and muscular fibres; pilocarpin, arsenic and iodine act upon certain glandular cells; phosphorous upon the process of growth in the bones.

When we come to analyze the cases known at present, however, how do we find it applicable to successful therapy? Bromides check epileptic convulsions for a limited period, but they do not affect the processes in the central nervous system.

Alcohol in measured doses stimulates for a time the action of the brain and heart, but does not act in a curative manner in any of the pathological conditions which may have rendered its exhibition necessary.

Morphine relieves the pain of neuralgia, but does not relieve the changes that cause the same. Digitalis relieves passingly the insufficiency of the cardiac muscle, tachycardia and arhythmia, but does not prevent their recurrence, neither does it restore to normal the fine or coarse anatomical foundations of these conditions.

The nearest approach to true cure or healing which we are able to produce by means of drugs, is seen in the action of iodine upon gumma and enlarged thyroid gland; but even here we must acknowledge that the true nature of the disease is entirely unknown to us. Even in the most favorable cases of unquestionable specific influencing of the diseased tissue in such a manner that the processes leading to recovery must be directly ascribed to the remedy, still, the receding of the disease in the true sense of the word is effected by the organism itself. To be sure, if circumstances analogous to those attending the action of iodine in enlargements of the thyroid were more frequent, the art of healing would be brought nearer to its ideal. Yet how pitiably few are these up to the present day! Whether or not we shall reach a goal by a similar train of thought which led our renowned Robert Koch to institute his experiments with tuberculin, clinical experience must show. Possibly the art of healing is destined to advance in this direction—at all events it forms a noble work of research, worthy of our highest endeavors. First of all, and even more with our advancement of knowledge, we must come to understand that the physician is only the servant of nature and not her master. Although, however, our outlook and possibilities may at present be very limited, yet this should offer no discouragement or cause us to give up our work without further endeavors. If Science cannot master Nature, it can at least follow faithfully, observing its mysteries. The warning sounded in the foregoing sentence gives the key to the secret of the success of truly great physicians.

We must carefully investigate and confirm the development, nature and results

of morbid changes, and also under what conditions and by what processes the human organism is capable of withstanding or recovering from these disturbances, and when possible in a suitable manner to cause or assist these processes, or to imitate them, and above all to do no harm. This is the way in which the art of healing can accomplish great and good ends. History shows most conclusively that parallel to the advance of our knowledge of scientific methods, our capabilities at the sick-bed have also advanced. Isolated exceptions prove nothing against this assertion. The exceptions are accidents, and we cannot count on accidents when we are endeavoring to extend the limits of our art.

Allow me, by the way of illustration, to quote one example. A cardiac valvular insufficiency as such we can never cure. How is it then, that in spite of the necessary change of circulation, accompanying such an insufficiency, the patient may live for years in apparent health and capable of work? The compensatory hypertrophy of a certain part of the heart is the cause of this, and the life-retaining hypertrophy itself is the physiological sequel of the above change of circulation. When this is recognized, and when we further have recognized that the extent of the hypertrophy corresponds in degree to the change of circulation which has caused it, and which it relieves, we may deduct the following, with reference to the art of healing: First, no effort should be made to check the development of this hypertrophy, as formerly used to be done; second, everything that might tend to hinder the development of this hypertrophy must be removed or kept away; third, we must not endeavor to excite the stronger action, by excitants, whatever they may be, so long as the condition of compensation remains. The organism has done its work, and our hands must not destroy or disturb it.

I will refrain from any further reference to any special instances, by which it may be seen that medicine of to-day, without being able to directly affect the process of the disease, by simply following the rule laid down above, viz., of watching and aiding the natural processes of restoration of the organism itself, can accomplish more in this way than by any other means. We have been taught above all things not to disturb the course of natural restorative processes. On the contrary medicine should endeavor to place the organism in a position which will enable it to vanquish the pathological process, either by dietetic, hygienic or climatic influences, or by a methodical stimulus to the material changes in the nervous system. The most careful and helpful assistance and watching—suited to the conditions, and our knowledge of the processes of the disease—designed always to aid the natural restorative and healing processes, this forms one of the paths in which we may tread in seeking to broaden the usefulness of our art.

With the knowledge that already developed pathological processes can only be influenced by our art to a limited extent, or perhaps not at all, medicine has recently entered upon an entirely new field of labor, from which it already reaps a blessed and costly harvest. And in fact, since in many cases we are not, and will not, be in a position to influence the results of disease in the organism, it becomes all the more our imperative duty to guard against the occurrence of the same, to recognize the cause of the disease and to render it harmless.

This duty should, however, be accepted in the fullest sense; not alone in the guardance against infectious diseases, and this again not alone in the enforcement of sanitary laws. The success of this work has caused us very commonly to ascribe a curative action to its influence, while in point of fact none such exists. By closely examining the fact, it will be seen that the results are obtained not by a process of cure in the scientific sense, but by a distinction of the cause of the disease.

When a potash solution which has been swallowed, has been immediately neutralized by the exhibition of vinegar or when the acarus scabiei has been killed by any local application, any one will understand that this is naturally only a removal of the harmfulness of the exciting cause of the disease, not a cure for the gastric lesion or cutaneous affection. But we must go much further in this line of argument; the curative action of many so-called specific remedies becomes subject to the same limitations. So the treatment of malaria with quinine must be, to all appearances, regarded as ætiological treatment. The

changes in the blood-corpuscles and in the spleen are not cured or restored by the alkaloid, but the plasmodiæ ofmalaria are in some way killed and the process of the disease in the tissues stopped.

As the acid renders the alkali harmless, thus removing the cause of disease, so does quinine render the plasmodium in the blood harmless.

The hope is by no means unjustifiable that in the near or perhaps more distant future, such a destruction of the exciting causes of the disease may be possible by means of the employment of specific remedies in other infections. After the destruction of the course of the disease, the nature process of healing can effect a cure of the existing disturbances: in typhoid fever, the intestinal ulcers; and the bronchitis in whooping cough. It is possible that advance in this direction may occur by accidental discovery, as was the case with quinine in malaria and salicylic acid in rheumatism. All the same, the opinion is not without good foundation that methodical investigations in this line may also be fruitful of success. And although the battle of opinions still wages here or there, and although many of the results as yet obtained, are only applicable to the diseases as found in animals, yet there is no real reason why the same results should not be reached in the disease as it appears in the human organism.

The most noteworthy endeavors of the present, move in three directions: the healing of bacteriological diseases that already have advanced as far as clinical manifestations; to render harmless infections still in the incubatious period; to guard against infections, or rather to prevent their occurrence.

The last named effort has been the one most advanced. It can accomplish its results by two different means. The one consists in the application of sanitary precautions against infection. It is very clear that the value of these precautions, their establishment and maintenance, becomes greater with the advance of our scientific knowledge. Cholera may be remembered as a good example. The other possibility is to prevent infection by rendering the individual organism immune. An unparalleled example of this may be seen in the precautionary inoculation, or vaccination, against small-pox. The result was reached by the simple clinical observations of the English physician whose name millions have already lauded in gratitude. To cause immunity by artificial precautionary inoculations, forms a scientific fundamental principle occupying a formost position in the advancing tide of research. Whatever favorable results it may ultimately obtain, the following is practical and clear: Even if we come to the possession of advanced methods in this line, we will only attempt preventive immunization in the case of such diseases of an infective nature, that affect the majority or at least many individuals and to the danger of which they seem most liable. So besides small-pox and possibly scarlet fever, would come under this category besides these, also whooping cough, pneumonia, diphtheria, typhoid fever and the epidemics most prevalent at the present time, including cholera, influenza, typhus, etc. Naturally geographical conditions would alter or modify this list. On the contrary, for many patent reasons, it is highly improbable that general preventative innoculations will ever be undertaken in such diseases as hydrophobia, anthrax, and tetanus. Such an advance would to-day seem rather visionary, but the possibility exists and we are already close to its fulfillment.

The second endeavor, namely, that of rendering harmless an already existing infection (which, however, is still in the period of incubation) has an existing paradigm in Pasteur's inoculation in hydrophobia. The number of this class of cases will of necessity always remain limited. The cause for this limitation is very apparent. In hardly any case can this period of the disease (the incubation period) be recognized at all, or can it be recognized whether the pathogenic germs have entered into the human organism or not. How may we determine, in the case of a perfectly healthy man, whether there are tetanus bacilli or the cocci of erysipelas in his system? We must have a tangible source before we can proceed, such as the bite of a rabid animal.

From a practical point of view, however, our endeavors will be in the direction of that goal, in which we will be able to find remedies that will render harmless the exciting cause of disease, even after the same has been clinically manifested. In what manner these remedies act, whether they act harmfully upon the mi-

croörganisms themselves, whether they render their nutritive soil in the organism unfavorable to their further growth, or finally, whether they increase the withstanding power of the cells (phagocytosis, or otherwise)—all these are secondary to the practical results achieved. The goal is an exalted one, but this is no cause for impossibility of attaining it, and its attainment would be a brilliant triumph for the art of healing. To be sure, even after its achievement, it would be a mistake to imagine that death from any disease in question could always be avoided. Even in such a case the severity of the disease remains a potent factor in the possibility of recovery, as has already been referred to in another part of this address. A sudden overloading of the organism with large numbers of the exciting factors of the disease, an existing lack of withstanding power of the organism, the institution of the treatment at the time when the extent of the tissue changes render it too late to be of any value, since the natural process of restoration cannot occur—all these will act as limitations to its usefulness.

Naturally the duty of the preventing and removing the cause of disease to the utmost limits, holds good in the most varied conditions, only the results of such a course are rarely so evident as in the treatment of bacteriological diseases. Very frequently the cause of the disease is entirely removed from any possible therapeutic influence. This is the case in that frequently referred to affection, "cold," the importance of which is frequently absurdly over-estimated, but which in some cases cannot be denied. In many cases the cause is even now entirely unknown, as in renal atrophy (Schrumpfniere) and leucæmia, as well as many other diseases. Or again, the cause may be in the patient's manner of life, social circumstances. To offer single examples of all these, would lead us too far.

Even the most important point I can here only touch upon most briefly, in the technical knowledge of which the power of the law and society itself must join hands in order to grasp strongly at the very foundation of the subject: I refer to the general maintenance and care of health.

And although our art is unable to effect healing by the impossibility of effecting the natural processes at our will; and even when it finds narrow limits in the prevention of diseases, even granting that such might be the case, even then its field of usefulness is by no means exhausted. There still remains an open field of extreme value, namely, the treatment of disease symptoms. Out of the countless number of pharmaceutical preparations the majority are valuable in this respect, and apart from these the value of mineral springs, bath-cures, electricity and numerous other therapeutic aids. We must not under-rate the vast importauce of this part of the art of healing.

For the sufferer it is frequently quite immaterial whether this or that functional change has taken place in his body, as long as he does not experience any trouble from the same, his capabilities for work not being lessened or his life shortened. Not this alone, but also something vastly more important. It is the symptomatic treatment alone that often creates the possibility for the natural process of healing or cure; it annuls those symptoms which are most dangerous to the life of the patient. Truly no one who has been a recipient of the successful treatment of a physician in œdema of the lungs or cardiac failure when the stamp of death has already been upon him, will think lightly of the value of symptomatic treatment. In this the art of healing is not only capable of great advancement but it is now rapidly making these advances in a most satisfactory manner.

While Griesinger only thirty years ago complained bitterly against the helplessness of the physician to reduce high fevers, we now, thanks to the cold-water treatment, and thanks to the discovery of a list of most energetic antipyretics, are able to keep the temperature of a patient suffering with typhoid fever, almost normal. Yet we no longer deceive ourselves as to the value of these proceedings. Antipyresis is only the relief of a symptom and then only questionably; the true process of the disease is not affected by it. Think of the number of hypnotics that have been given to us in the past four years—a welcome addition to the old king of hypnotics, opium. Then again the number of antiseptics; and pilocarpin, cocaine, diuretin, and many others. Equally fruitful has been the introduction of symptomatic curative methods. In this respect we need

only refer to the pneumatic apparatus and irrigation of the stomach.

"In all we see life and active work,
Budding branches and ripe fruit!"

And in all this how humbly must we acknowledge our ignorance. Every human life that ends prematurely, every one whose life of usefulness is endangered by processes we cannot overcome; these show the limits of our lot. And what is more poignant, the knowledge that certain difficulties we may never overcome, certain limits never overstep, and never master the processes of life itself.

We would only desire to extend vastly the limits of our field of usefulness, and no matter how slowly we progress or how many set-backs we meet with, yet spurred onward with ardent enthusiasm, we look always toward that guiding star, in the light of which we seem to read that—

"To work in the service of mankind,
Is the noblest duty of man."

PROLAPSE OF THE EXTREMITIES IN HEAD PRESENTATIONS.

J. Kaeser (*Centralbl. f. Gynäk.*, No. 2 1892), from a study of recorded cases, finds that prolapse of the extremities is far commoner in multiparæ than in primiparæ. The complication is favoured by hydramnion, contracted pelvis with previous heavy labors and twin gestation, since in these conditions the inferior uterine segment does not press on the head with firmness sufficient to prevent prolapse of the extremities. Prolapse of the arms is less serious than prolapse of the legs, but the cord often comes down as well in these cases, and, that condition is very grave for the child. When the membranes are yet entire the obstetrician must wait till the os is completely dilated. Then the protruding extremity must be pushed up and the head brought well down by external pressure. After rupture of the membranes, manual reposition of the prolapsed member must be effected; if this proves unavailing and the head is movable, it will in many cases be advisable to turn. When the head is firm, reduction of the extremity should be cautiously attempted in the intervals between the pains. If this should fail, then according to the nature of the case in other respects, natural evolution may be awaited, or the forceps or perforator may be required.—*Brit. Med. Jour.*

REFLEX URETHRAL AND GENITAL NEUROSES; URETHRAL NEURALGIA AND HYPERÆSTHESIA; HYPERÆSTHESIA AND NEURALGIA OF THE TESTES.

By G. FRANK LYDSTON, M. D.,
CHICAGO, ILL.

There are a few morbid conditions of a functional character which, although oftentimes an integral part of organic diseases of the organs which it is my special province to consider, are occasionally either morbid entities or else the prominent source of complaint on the part of the patient, indeed we are apt to be more often consulted regarding these functional or nervous derangements than the diseases upon which they frequently depend.

There is, perhaps, no subject in the whole range of genito-urinary disturbances of greater importance than the varied phenomena involving nervous derangements that are due, directly or indirectly, to pathological conditions of the various portions of the urethral canal. It is certain, also, that in no class of cases which come under the observation of the genito-urinary surgeon, is an accurate diagnosis of greater importance, or more difficult to accomplish. I feel, therefore, that a contribution to the special study and treatment of such cases is, to say the least, warrantable.

When we consider the vast amount of labor and talent that have been devoted to the study of the reflex neuroses of the female due wholly or in part to pathological entities affecting the uterus and its appendages, it is certainly surprising that more attention has not been given to analogous conditions in the male due to disturbances of the generative organs and especially of the urethra.

Taking as our point of departure the prostate body, we will find quite a close similarity between some of its morbid conditions and those affecting the uterus. Physiologically, the prostate, or at least a portion of it, is the homologue of the uterus, there being the closest resemblance in the muscular structure of the two bod-

ies. If the muscular tissue becomes perverted in growth, we have in the one, uterine myoma, and in the other, prostatic hypertrophy, the structure of the two morbid processes being strikingly similar. When, as is occasionally the case, the "third lobe" of the prostate becomes so circumscribed as to form a distinct tumor, it is generally not unlike a pedunculated fibroid. It will also be found that certain remedies which have a pronounced action upon unstriated muscular fibre, have a somewhat similar action upon the prostate and uterus, this being especially true of secale, ustilago maidis, and hammamelis. Certain sedative remedies act very similarly upon irritative affections of the uterus or ovaries, and the prostate. To carry the argument a little further and directly approach the subject of neuroses, it will be found that certain irritations affecting the prostate, will produce effects quite like those produced by utero-ovarian irritation in women. False spermatorrhœa (spermatophobia) pseudo-impotency involving disgust for the sexual act, melancholia, hypochondria, neuralgias whether of the contiguous or remote nervous filaments, and nervous inhibition amounting to almost complete paresis, are all possible results of urethral or prostatic irritation, and these conditions are all represented by similar disturbances, such as hysteria and allied conditions in the female, due to morbid conditions of the generative organs. The analogy between the results of prostatic catarrh and those of cervical catarrh, as shown in one of the cases herewith reported, is sometimes especially striking.

One of the interesting features of stricture of the urethra, is the ensemble of symptoms of a nervous character that is so often seen, and which neuroses are frequently entirely disproportionate to the degree of organic trouble present. Cephalalgia, neuralgia in various localities, particularly sciatica, lumbar and intercostal neuralgia, are quite common, but are probably regarded by both physician and patient, as coincidences rather than as bearing any consequential relation to the stricture. Associated with these are others (quite as prominent in some cases) of a purely mental character, such as melancholia, hypochondria, disturbed sleep, incapacity for intellectual effort, and deterioration of business capacity, perhaps associated with great irritability of temper. Disturbed digestion and general faulty nutrition are constant. That these various morbid conditions depend upon the stricture is never fully appreciated until that organic entity is cured, when the complete restoration to health demonstrates their true relation to the primary source of irritation. Many of my patients tell me that they had become so accustomed to their little ailments that they had come to consider them a matter of course and had never dreamed of their association with the stricture until the latter was cured. One of my patients remarked that he did not know how sick he was until he had been cured of his stricture.

Certain cases of gleet are associated with considerable mental depression which is commonly attributed to the moral effect of the supposed drain upon the system. This mental disturbance I believe to be in many instances the result of reflex irritation through the sympathetic system, which is so closely associated with the functions and nutrition of the sexual organs.

Morbid conditions of the urethra not only cause neurosis in other portions of the body, but they are often a reflex result of disease of contiguous structures; thus I have noted cases of spasmodic stricture dependent upon hernia and varicocele. Dr. Otis has described some very interesting cases of chronic spasmodic stricture of reflex origin. Operations about the anus are very often followed by spasmodic stricture and urinary retention. Morbid conditions of the anterior portions of the urethra often cause reflex disturbances of the deeper portion of the canal, or indeed, of the bladder. This is very familiar in connection with the results of contraction of the meatus.

One of the most annoying complaints which the surgeon is called upon to treat in connection with the genito-urinary apparatus, and especially in stricture, is neuralgia and hyperæsthesia of the urethra. This disorder is most often the result of long standing urethral inflammation, or stricture with its attendant gleet, and frequently persists long after organic disease has apparently been cured. The majority of patients who suffer from urethral neurosis of this kind are either of an emotional highly sensitive nervous organiza-

tion—often simulating "hysteria" in the male—or of a gouty temperament with highly acid and concentrated urine; anæmic and cachectic patients are especially liable to it if nervous or rheumatic. In such patients the imagination has been over wrought by the dread of serious results from urethral disease, and the mind depressed by a sense of self-degradation. The condition of the mind as well as that of the urethra has been impaired by long continued treatment of something which although trifling in itself perhaps, is to the patient, a terrible morbid entity, and a mental incubus from which he is never free except during the hours of sleep. Quack literature, irritating injections, over enthusiastic treatment, sexual starvation and excitement without gratification, are all disturbing elements in his case, and if we superadd the results of dissipation, intemperance and dietetic errors, what wonder is there that he never gets well, or that he magnifies the slightest unusual sensation about his sexual organs into something new, serious and startling. Such patients will say to us when we try to convince them that their gonorrhœa, gleet or stricture is practically well; "But doctor, I am not quite right. I have a funny feeling at this point in the canal," or the complaint will be varied by a description of severe burning or cutting pains in the canal during micturition, or a tender spot usually near the meatus. Sometimes the pain radiates to the other portions of the sexual organs. On examination with the urethroscope, nothing appears which would account for the trouble; and treatment is usually of little avail, unless we succeed in obtaining the patient's confidence and inducing him to believe that his trouble is not organic and will soon wear away—only too often however, he goes from surgeon to surgeon in the vain endeavor to find relief, until despairing and disgusted he resigns himself to what he considers inevitable fate and lapses into confirmed melancholy and hypochondria. Great irritability of mind alternating with depression and melancholia. Morbid states of the prostatic sinus and vesical neck with or without co-existing stricture occasionally give rise to urethral neuralgia; vesical calculus and tumors are especially liable to be complicated by it. Hyperæsthesia of the urethra is so often associated with stricture and gleet, that it is worthy of consideration in every case in which obstructive spasm occurs during instrumentation; some canals will be found to be so hyperæsthetic that a chronic spasmodic condition exists. In some cases of chronic spasmodic stricture or urethrismus, local lesions of the mucous membrane exist, while in others nothing abnormal is to be detected.

Hyperæsthesia of the testicle, is an interesting condition which sometimes results from reflex irritation from stricture; more often however it is due to excessive sexual indulgence or the opposite extreme, i. e., ungratified and prolonged sexual desire. It is most apt to be associated with cachexiæ, gout, neurasthenia or anæmia. The testicle may be relaxed and soft, or full and firm to the feel. Oftentimes varicocele is present and acts as an efficient cause for the affection. Hypochondria, melancholia and various mental perversions of a delusional character are not unusual, and may perhaps be associated with a sluggish portal circulation or dyspepsia. Sudden deprivation of customary sexual indulgence is said by Curling to be a frequent cause.

The symptoms consist in extreme sensibility and tenderness either of the entire testicle or some spot upon its surface. So exquisitely tender is it that oftentimes the contact of the clothing and the various bodily movements cannot be borne.

Neuralgia of the testicle, is really an exaggeration of hyperæsthesia, and has in addition to hyper-sensitiveness, paroxysms of shooting cutting pain in the organ. The causes are much the same as for hyperæsthesia-syphilis, gout, and malaria having a prominent place in its ætiology. Urethral stricture quite often and prostatic and bladder disorders occasionally cause it. The pain is much like that of renal colic and is sometimes attended by retraction of the testis from spasm of the cremaster and the sick, faint feeling and cold perspiration characteristic of shock. I believe that some cases are really due to irritation of the renal pelvis and ureter by sharp crystals in the urine, and this acting reflexly produces pain in the testis. Usually only one testis is involved. As a rule the patient can walk about but in the severe cases he is apt to be greatly prostrated, and in addition he usually suffers from pain and soreness on movement.

The treatment of the neuroses which

have been presented consists in following some very plain indication as well as putting in practice numerous general principles. First and most important of all is attention to the patient's mental condition. His mind should be diverted from his physical ills, and at the same time kept free from all sources of sexual disquiet. Questionable literature and the society of loose woman must be avoided; in short, an attempt should be made to correct the impression so prevalent among men, that man's chief mission upon earth is the procurement of material wherewith to cloy his sexual appetite. *Once dispel the idea that his penis and testes constitute the axis around which his earthly existence revolves; and one will have done more for his patient than if he had fed him the entire contents of a drug store.* Having allayed sexual disturbances of a purely mental or moral character, it remains for us to secure for our patient physical sexual rest, it being sometimes a matter of nice judgment to determine whether moderation or strict continence is best for the patient's welfare. In a general way it may be said that those neuroses which are dependent upon or complicated by actual inflammation, acute or chronic, demand absolute continence, while in those of a purely nervous character, moderation is to be advised. It is always a hard matter to determine the degree of success of our prescription in this matter, as the patient's penis is not only quite liable to gain the mastery over his reason and judgment, but over his morals as well, and he will therefore be apt to consider that a lie to his doctor, like Rip Van Winkle's drink, doesn't count.

Second only to sexual rest is the correction of urinary activity. This may be corrected by diet and remedies combined, the diet being by far the most important. The proper standard for a suitable diet is bread and milk, but this may be varied within narrow limits. Nitrogenized food, stimulants and tobacco must be strictly prohibited. As an adjuvant to this regimen, the Turkish bath does excellent service.

The best remedies to correct hyper-acidity of the urine, are the acetate and citrate of potassium, liquor potass, and in gouty or rheumatic patients (who are especially liable to neurotic symptoms from urinary disturbances) lithia, colchicum, and salicylic acid. Mineral waters are very useful, the Buffalo lithia and Waukesha waters being especially useful. Several of my patients claim great benefit from partaking freely of the Garfield Park mineral waters.

Sedatives and anti-spasmodics are often useful in these cases, the following being of service in different cases, viz: potassium bromide, gelsemium, hyoscyamus, camphor monobromate, morphia, salixnigra and ergot. Tonics are often required, the best being the chloride of iron, strychnine, arsenic and quinine. In those rare cases of spasmodic stricture of malarial origin, quinine is of course a specific. Three very useful drugs are the phosphide and bromide of zinc, and the bromide of arsenic, these being great favorites of my own.

In many cases of urethral neurosis, surgical interference is required, thus a contracted meatus must be cut, a stricture dilated or cut, hernia or a varicocele operated upon or properly supported, etc. *The paramount indication from a surgical standpoint, is the relief of obstructive and inflammatory lesions of the genito-urinary tract.*

Cases of irritability and hyperæsthesia of the testes are by no means promising. The use of anodynes is ordinarily reprehensible as the disease is chronic in character and a narcotic habit may be readily acquired. If hygiene, the steel sound, the suspensory bandage and marriage do not cure, the case is apt to be hopeless. Galvanism and the application of ice bags are said to be of service. Castration is not to be thought of, but the idea suggests itself to me that in an obstinate case, stretching the spermatic cord with incisions into the tunica albuginea might be successful in curing the neuralgia. Hammond suggests pressure upon the cord for the relief of the obstinate cases, upon the theory that in this way the sensibility and conductivity of the affected nerve fibres will be obtunded.

A very interesting case showing the great annoyance which may reflexly arise from slight irritation of the genito-urinary tract came under my observation a few days ago. A gentleman 28 years of age had been troubled by frequent micturition especially a night for some years. At times he would be compelled to rise four or five times at night to evacuate his bladder. The only point in his history of any

importance was a gonorrhœa some seven or eight years ago. He confessed to masturbation and sexual excess in times past, but stated that sexual apathy and incapacity had prevailed of recent years. On examination I found a meatus which had been badly cut by some surgeon one year ago. Just within it was a very irritable and resilient stricture of a calibre of twenty Fr. Not a stricture perhaps, in the eyes of some surgeon, but a decided stricture in my opinion. This contraction was so irritable that attempts at exploration threw the entire canal into a state of spasmodic contraction. I found it impossible to pass a bougie through the deep portion of the canal. Cocaine was applied and a meatotomy at once performed. As soon as the meatus was free, I passed a 32 Fr. solid steel sound into the bladder without the slightest effort. The night of the operation the patient had the first uninterrupted sleep that he had enjoyed for years, this experience being repeated every night following until he left for his home in the west.

We have here a case of vesical and prostatic hyperæsthesia, and chronic spasmodic stricture—urethrismus—instantly relieved by removing the reflex sources of irritation, a resilient irritable meatal contraction.

Another interesting case of a somewhat different type is at present under my care. This case shows how posterior irritation may reflexly excite disagreeable symptoms in the anterior portion of the genito-urinary tract. A young man of twenty-five who had suffered from several severe attacks of gonorrhœa, presented himself to me complaining of severe burning and and hot, lancinating pains along the pendulous urethra, localized at times at a point one inch posterior to the meatus. These painful symptoms were chiefly manifest after urination although present in the intervals. The patient was extremely neurotic and suffered from sexual hypochondriasis. Otherwise he was in a normal condition. The urine presented no pathological features, save *tripper fäden* and mucous casts of the prostatic follicles of the characteristic horse-shoe nail variety.

Examination with the bulbs showed a urethral calibre of thirty-four French, and an absolute freedom from contractions. There were several points of tenderness in the penile urethra, and excessive tenderness in the prostatic region. Rectal examination showed the prostate to be slightly enlarged.

I made the diagnosis of urethral neuralgia and hyperæsthesia dependent upon posterior urethritis and follicular prostatitis.

There was no cutting to be done, and the treatment therefore consisted of intermittent dilatation with large sounds, and the application of nitrate of silver solution to the prostate. These applications were alternated with the application of the continuous current, positive pole, to the deep urethra. Internally tonics were given, the Tr. ferri chlor. being mainly relied upon. The case has slowly but markedly improved, a fact which is particularly gratifying in view of the stubborness of of such cases.

I wish to state in passing that I envy those surgeons who have such brilliant success in the management of this type of genito-urinary neurosis as is claimed by some. Personally I had rather see the gentleman with the cloven hoof walk into my office, than one of these patients.

The explanation of the obstinacy of such conditions is to be found chiefly in faulty sexual hygiene, a matter over which we have but little control.

As illustrative of the interesting character of some of the cases described, I take the liberty of presenting the following, selected from my case book:

Case I. Reflex vesical irritability and intercostal neuralgia from contracted meatus. W. R. age 39. This gentleman had had numerous attacks of gonorrhœa in his youth, the last attack having occurred about fifteen years ago. Since this last attack he had been troubled with frequent micturition, necessitating his rising six to eight times during the night, and causing great irritability of mind. Micturition was occasionally quite difficult, requiring fifteen or twenty minutes for its completion, the stream being especially slow in starting. Every spring and fall and whenever he was overworked he suffered from a severe attack of pleurodynia, which had been variously diagnosed as pleurisy, impending pneumonia, cardiac neuralgia, intercostal neuralgia, etc. In two of these attacks in which I attended him, there was an elevation of temperature of about four degrees, with considerable

prostration, leading me to believe that the attacks were of a rheumatic character. On examination of the urethra, I found the meatus so small as to barely admit a small probe, and excessively tender and inflamed. A slight gleety discharge was noticeable, which the patient stated had been a constant symptom for years. I at once enlarged the meatus to 34 French, and attempted a thorough exploration of the canal. I found that steel sounds would not pass the muscular urethra on account of the intense spasm which they induced, soft bougies, however, passed readily up to 18 French. Above that size could not be passed without producing intense pain. No organic contraction of the canal could be demonstrated by either the urethrameter or *bougies a boule*. The second night after the meatotomy, the patient slept soundly for the first time in some years, and he has continued to secure his natural rest ever since, it being now three month since the operation. The flow of urine has become quite free, and starts as soon as an attempt at micturition is made, the act of micturition being of normal frequency. A marked improvement in the general health is noticeable and the nervous irritability has in a great measure disappeared. There has been some increase of weight, but as the patient is naturally spare, this has not been very marked. The attacks of pleurodynia have not recurred, although the usual time for their occurrence has passed; and as time goes on, I am confident that the theory of their dependence upon the urethral irritation will be confirmed. The gleet has disappeared entirely, and there has been a decided increase of sexual vigor; in short, as the patient expresses it, he is "himself again."

Case II. General sympathetic disturbance and neuralgia of the testes, from stricture of large calibre and follicular prostatitis.

J. G. R. aged 45. This gentleman had several attacks of gonorrhœa, the last one having occurred some twenty years ago. For the last four years he had been suffering with irritation of the urethra, which had been referred to stricture, and treated by dilatation. Later on he had been "quacked" for diabetis, prostatic enlargement, Bright's disease, rheumatism, and several other afflictions, with no effect save to convert the patient into a confirmed hypochondriac. At the time he consulted me, he had been suffering from paroxysmal pain in the testes, with occasional "burning" sensations in the testes, perineum, and cranial vertex, and pains of a rheumatic character in the limbs. On examination of the urethra I found that it would admit an 18 English sound quite readily save some pain was experienced at a point one inch from the meatus. At this spot the *bougie a boule*, demonstrated the existence of a linear stricture of large calibre. The prostate was found to be somewhat tender, but not enlarged. On examining the urine I found that it contained membranous shreds, which from their appearance I judged to be from the prostatic urethra, and the result of follicular prostatitis. A slight gleety discharge was noticed, evidently of a similar origin.

The meatus and stricture were cut to a 40 French, with a complete relief to the neuralgia of the testes. The rheumatism in the limbs has greatly improved, but the feeling of heat in the testes, perineum, and head has in a measure persisted, although much better. These latter symptoms I attribute to prostatic irritation, more particularly because applications to the prostatic sinus, of a sedative or astringent character, produce a marked and speedy amelioration of them. I have found also that the shreddy appearance of the urine was increased by each application to the prostate. Hot boracic acid irrigation has been substituted for these applications, and the case is slowly improving. The connection between the neuralgia of the testes and the stricture in this case is demonstrated by the improvement resulting from urethrotomy.

Case III. Pseudo-impotence from contracted and irritable meatus. This case and Case IV I will not give in detail, but will present the salient points:

A young man of 27 had suffered from several attacks of gonorrhœa, the last of which ran into a gleet which lasted about a year. There had been no trouble with urination, but about six months before I saw the patient, he noticed a loss of sexual power. He would suddenly succeed in securing an erection at times, but erection would suddenly cease in the act of copulation. On examination I found the penis and testes apparently normal, but the meatus was quite narrow and excessively sensitive. There was no deep or penile stricture.

The meatus was incised to 34 French,

and sounds passed to the bladder every third day for several weeks. At the end of a month improvement was reported, and in about two months the patient reported himself as entirely recovered from his sexual disability.

Case IV. Vesical atony from contracted and irritable meatus.—This patient, 40 years of age and a gambler by profession, gave the usual history of numerous gonorrhœas and also of syphilis. Micturition had for a long time been attended by pain and smarting at the meatus, and a slight gleet had been present for some years. For about a year the stream had grown less and less forcible, until quite a strenuous effort was necessary to empty the bladder. On examination the meatus was found to be only moderately contracted, but very tender, the lips being everted and reddened. No deep strictures were discoverable. The feeble flow of urine through the catheter demonstrated the vesical atony. As the obstruction was only moderate and was congenital, the atony was explicable only upon the theory of reflex spasm of the cut off muscle and inhibition of the detrusor urinæ. Meatotomy to 40 French resulted in an almost complete cure as demonstrated by examination six months after operation.

Other cases of a neurotic character have occurred in my genito-urinary practice, but these cases will serve for the purpose of illustration. In all my cases, due attention has been paid to general hygienic and medicinal measures, but the details of treatment would simply result in prolixity, without adding to the value of the report.

I have found that reflex neuralgia of the testis, penis and cord, and chronic spasmodic stricture are by no means rare, as several instances among my patients serve to demonstrate.

FATAL POISONING BY CHLORATE OF POTASH.

Dr. M. J. Donahoe reports in the *University Medical Magazine* for January a case of a man thirty-six years old who took by mistake two tablespoonfuls of chlorate of potash in water. Four of five hours afterwards violent vomiting set in, accompanied by great pain and tenderness in the epigastrium followed by albuminuria, and cardiac weakness, gradually increasing for a week, when the patient died.

CLINICAL CONTRIBUTION TO THE STUDY OF HYPERTROPHIC HEPATIC CIRRHOSIS.*

By DR. FREGHAN,

BERLIN, GERMANY.

Laënnec regarded hypertrophic cirrhosis as the early stage of ordinary atrophic cirrhosis of the liver. Todd, in 1857, was the first to try to show that an essential difference existed between the two forms. In 1859, Charcot and Luys contributed a short report to the Société de Biologie, supporting the same view on purely pathological grounds. Dr. Freghan very frankly admits that race prejudice prevented the Germans from giving a proper consideration to these investigations. Other investigators, however, followed up the studies of Todd, Charcot and Luys and with substantial aggreement.

Dr. Freghan reports four cases of hypertrophic cirrhosis, all of which showed very similar symptoms and presented nearly identical post-mortem appearances.

Case I. was that of a saloon-keeper aged 51, with good family and previous personal history. His habits had been correct with the exception of moderate indulgence in alcoholics. The disease had developed gradually in the last three months, the patient complaining principally of increasing weakness, loss of appetite and indigestion. Vomiting and profuse diarrhœa were recent symptoms, the bowels having previously been regular. For six weeks there had been jaundice with light colored stools, enlargement of the abdomen and swelling of the legs, particularly toward evening.

Condition on entrance:—The patient is a large pretty perfectly built man, moderately well nourished; icterus marked and general, including the conjunctivæ and upper air-passages. Considerable œdema of the lower extremities, tongue slightly coated; appetite not bad; temperature 97.6° pulse 108, respiration 24; urine scanty, dark-brown, with a yellow foam on shaking; much bilirubin present and a trace of albumin. The urine after standing deposited a sediment of isolated epithelial cells, pus cells and hyaline casts

*Condensed translation by A. L. Benedict, A. M., M. D., from the *Archiv f. Path. Anat. u. Phys. u. Klin Med*, April, 1892.

tinted yellow. Bowels sluggish, fæces hard and grey and of the consistence of clay. Lungs normal except for moist râles posteriorly; heart normal. "The abdomen is half-cannon.belly forward arched." No trace of collateral venous anastomosis; no tenderness on pressure; vague fluctuation inferiorly. Percussion verifies the expectation of ascites which is moderate and freely movable; liver greatly enlarged and plainly palpable; left lobe is the most hypertrophied and can be traced far into the left hypochondrium, no irregularities can be felt. The margin is rounded and the consistence of the whole organ strikingly hard. Liver reaches from the fifth rib to a hand's breadth below the arch of the ribs. The spleen is not palpable but on percussion is found to be enlarged, reaching from the eighth to the twelfth rib.

Course of the disease. The temperature remained about normal,the pulse continued rapid. The general symptoms became worse and worse and the patient's strength fell gradually but without remission. The icterus remained stationary. After eight days in the hospital the constipation was succeeded by watery but normally colored stools. The ascites increased very slowly but the patient complained so incessantly of the weight and distension that on September 11, eight weeks after admission to the hospital, the abdomen was tapped and 3000 c. c. of deep yellow fluid removed. Microscopical examination of the fluid revealed nothing. The tapping afforded only temporary relief. Four days later, the patient's intellect became disturbed and his speech was irrational and the articulation indistinct. For several days preceding, he had suffered from headache. A condition of sopor slowly deepened into coma with involuntary evacuations of urine and fæces and heavy labored breathing, and on September 21, death resulted.

Autopsy.—Diagnosis: Hypertrophic hepatic cirrhosis, enlarged spleen, ascites, laryngitis, pharyngitis, catarrhal bronchitis, œdema of the lungs, hypertrophy of the heart, arterio-sclerosis, parenchymatous nephritis.

Skin brownish yellow, face pale, considerable œdema of the lower extremities. Mucous membrane of the air passages and pharynx icteric and covered with a mucopurulent secretion. Small quantities of clear yellow fluid in both pleural cavities. Left lung slightly adherent to the chest wall at the apex. On pressure, foamy fluid exudes from the bronchial tubes. Very little serum in the pericardium. Heart broadened. Tar-like fluid blood in the left ventricle and also strongly icteric chicken-fat clots. Valvular apparatus intact. Atheromatous changes above the aortic valves. Heart muscles yellowish brown, friable. The abdominal cavity contained about 4000 c. c. of turbid, somewhat fibrinous, dark yellow fluid. Intestines inflated and floating on the surface of the fluid. Serous coat of intestines slightly roughened and thickened in places. The stomach contained dirty brown fluid, its mucous membrane was markedly reddened in places and particularly near the pylorus. Gall duct patulous and discharging normal bile on pressure. Intestinal contents yellow in the jejunum, more brownish in the ileum. Mucous membrane of small intestines slightly reddened and loosened, the injection increasing toward the large intestine. Spleen enlarged by half, capsule greatly thickened. Section shows a bluish red color interspersed with dark blue pigment. Kidneys large and thick. Capsule strips quite easily. Surface smooth but with a few slight depressions. Marked congestion seen on section. Papillæ pale and abnormal. Cortex thickened, glomeruli moderately injected. Liver very large, left lobe particularly involved. Surface uneven and marked by numerous granules of various sizes. Granules nowhere sharply limited but marked mostly only by slight and gradual depressions so that there was no great change of level at any place. Surface appears like shagreen with a ground color of pale yellow on which brownish zones were conspicuous. Weight of liver 3100 grams (more than twice the normal weight). Texture, firm and tough. On section, the arrangement of acini can still be detected, the acini appearing as dark brownish red in the midst of broad streaks of yellowish grey connective tissue. Venous channels patulous. Gall bladder contains about 30 c. c. of quite normal bile and a smooth gall stone of the size of a hazel-nut. Common and hepatic ducts and intra-hepatic biliary passages much dilated and everywhere patulous. Their mucous membrane is intact throughout.

Case II. was that of a butcher aged 29

with good family and fair previous personal history except that he had quinsy in his youth and that he was addicted to the use of alcoholics. He presented about the same symptoms as the first patient, and, in addition, he had twice vomited blood to the amount of a pint on the same day. The hæmatemesis had not been repeated. As in the first case, there was a good physical development, normal temperature, rapid pulse, œdema, the last more general than in the first patient, jaundice. The stools were copious, loose, of normal color. There was bronchial catarrh and a mitral direct murmur. The liver and spleen were enlarged as in the first case. Eleven days after entrance, an exploratory laparotomy was made which verified the first diagnosis and revealed no opportunity for improving the patient's condition. There was some suspicion of ecchinococcus cyst, since the patient had had much to do with dogs. The course of the disease was steadily downward. The diarrhœa and the jaundice, including the coloration of the urine, continued. Once there was hæmatemesis. The temperature never exceeded 100.40,° while the pulse remained constantly above 100. The last stage of the disease occupied four or five days, beginning with great restlessness and loud complaints of pain. The patient tossed about and writhed in the bed-clothes but there was no delirium. This condition very quickly gave place to coma from which the patient could scarcely be aroused by shouting and shaking. The pupillary reaction remained.

Tubercular broncho-pneumonia was found post-mortem. The heart was relaxed but the valves were competent in spite of the mitral direct murmur. Three thousand c. c. dark yellow fibrinous fluid was found in the abdominal cavity. The intestines presented the same thickening and roughening of the serous membrane. The gastric mucous membrane was reddened and swollen, especially in the cardiac portion. That of the intestine was in places injected and covered with a bloody fluid. The kidneys were congested and the cortex somewhat icteric in streaks. Otherwise the kidneys were normal. The spleen was large and congested, its capsule thickened, the Malpighian bodies indistinguishable. The liver weighed 3,900 grams. Its serous covering was roughened and flecked with gray. The surface of the liver was uneven from projections of the parenchyma. The consistence of the liver was about as in the first case—tough. The gall bladder and biliary passages were normal.

Case III. was that of a saloon keeper aged 36 addicted to the use of alcohol to the amount of twelve or fifteen glasses of beer daily besides other spirits. Since spring he had suffered from pains in the upper part of the abdomen but which never became intense. Except for the longer duration of the trouble, about eight months, and an early remission, the history was not very different from the previous two. Ascites could not be demonstrated. The lungs were emphysematous and there was much bronchial catarrh. The spleen was so much enlarged as to be palpable. There was little change till two days before death when delirium suddenly set in. After about twenty-four hours coma ensued and death took place soon after with pulmonary œdema. The post-mortem diagnosis was hypertrophic hepatic cirrhosis, hyperplasia of the spleen. broncho-pneumonia of the lower lobe of the left lung, pulmonary œdema, old tuberculosis of the upper lobe of the right lung, purulent bronchitis, gastritis, enteritis. The liver weighed 4500 grams.

Case IV. was that of a man aged 34 who was also addicted to drink. The urine contained albumin and hyaline casts stained yellow. The temperature and even the pulse were normal. The patient was apathetic and made little complaint. Four days after admission he became still more stupid and, soon after, comatose. Death came suddenly. The post-mortem diagnosis was made of hypertrophic hepatic cirrhosis, enlarged spleen, ascites, pulmonary atelectasis, catarrhal bronchitis, pulmonary œdema, gastritis, enteritis. As in the third case, there was only 400 c. c. of fluid in the abdomen. The liver weighed 3500 grams. The biliary passages, as in all the other cases, were patulous.

A microscopic examination was made of the livers from the third and fourth cases, with almost identical results. There was a general and marked formation of new connective tissue. The whole parenchyma was interlaced with anastomosing lines of connective tissue of varying thickness. The new formation of connective tissue did not occur in the acini, but was most

marked in the lobules and was arranged in bands radiating between the liver-cells. The islands of hepatic tissue thus formed were irregular in size and shape and the rows of liver-cells were so compressed and distorted that the original structure was with difficulty recognizable. At times the process of formation of new connective tissue was marked by collections of white blood corpuscles and the connective tissue was composed of fine fibrils interrupted by only a few small nuclei. The liver-cells did not seem to have been destroyed although they appeared, almost without exception, flattened and atrophied in varying degrees. There was no indication of fatty degeneration or a retrogressive metamorphosis. The nuclei remained distinct and took the stain well. In the bands of interstitial tissue were numerous nearly-formed biliary-channels. They possessed a distinct wall lined with cubical epithelium. Their course was at times serpentine, at times nearly straight.

Dr. Freghan proceeds to discuss the various views taken of hypertrophic cirrhosis. Charcot compares it to an experimental hepatitis produced by ligation of the common bile conduit, the former resulting from trouble with the smaller biliary passages, the latter from obstruction to the main duct. Both of these diseases he contrasts as biliary forms with ordinary atrophic cirrhosis which is a venous form of disease. Attempting to follow out this theory, Charcot describes the newly-formed connective tissue of atrophic cirrhosis as being located primarily about the twigs of the portal vein and spreading thence to other parts of the lobule. In hypertrophic cirrhosis, however, he declares that the interstitial formation follows the course of the biliary passages and is located at the periphery of the acini. In this way Charcot explains the frequency of icterus as a symptom of hypertrophic cirrhosis whereas the typical symptoms of atrophic cirrhosis are those of portal obstruction. Ackermann and several others have, however, disproved Charcot's plausible theory of the connective tissue. Ackermann suggests that the essential difference between the newly-formed connective tissue in the two kinds of cirrhosis is its retractile tendency in atrophic cirrhosis and the lack of such a tendency in hypertrophic cirrhosis. He considers as analagous the difference between ordinary cicatrical connective tissue and that formed in elephantiasis and in chronic obstructive hyperæmia. According to Ackermann, hypertrophic cirrhosis is primarily an affection of connective tissue while atrophic cirrhosis consists essentially in a degeneration of parenchymatous cells. Ackermann and Rosenstein compare the hepatic cirrhosis to kidney lesions. Rosenstein compares hypertrophic cirrhosis to the large kidney and particularly to its second stage, and atrophic hepatic cirrhosis to the common contracted kidney.

[Note.—If by "large kidney" is meant the large white kidney and if the "second stage" refers to the fatty and contracted kidney, the analogy does not seem well taken since both of these are lesions of parenchymatous degeneration, while the common contracted kidney marks an interstitial change.—A. L. B.]

To quote Dr. Freghan literally, "The Ackermannisch theory, yes, in many points doubtless overshoots the mark."

Dr. Freghan takes a conservative position with regard to the difference between atrophic and hypertrophic cirrhosis, believing that the former may have an initial stage of increase in the size of the liver and the latter a final stage of shrinking. He lays down, however, a typical triad of symptoms for hypertrophic cirrhosis, namely, (1) enormous, usually gradual increase in the size of the liver, (2) intense icterus usually accompanied by colored stools; (3) ascites lacking or slight. Symptoms of secondary importance are the almost constant enlargement of the spleen and the tendency to gastro-enteritis of hæmorrhagic type. The disease usually occurs between the *second* and the beginning of the *third decennium*s. [Dr. Freghan's four cases were aged respectively 29, 34, 36 and 57]. "The temperature changes are mostly within the normal limits, and evening exacerbations occur seldom." The pulse was about 120 in three of the four cases. This symptom has not been found mentioned in other articles on hypertrophic cirrhosis, The last stage of the disease is attended by an increase of temperature usually with delirium, sopor and coma successively. Cholœmia terminates the chain of symptoms. The duration of the disease is usually stated at three or four years but in this series of four cases it varied from four weeks to one year.

Maugelsdorf could find in the whole literature of atrophic cirrhosis only eight cases reported in which there was icterus; so that this symptom alone has considerable diagnostic value. The differential diagnosis must be made between hypertrophic cirrhosis and tumors. Intra-hepatic tumors are usually carcinoma and multilocular hydatid cysts. The former has icterus and the enlargement and hardness of the liver in common with hypertrophic cirrhosis, but the surface of the liver is usually uneven although the inequalities may not be palpable. The moderate ascites and the earlier age of hypertrophic cirrhosis are diagnostic points. The hard rounded prominences of ecchinococcus cysts, becoming soft later, the tenderness of the liver and its irregular contour distinguish it from hypertrophic cirrhosis. The disease must also be differentiated from a second category of tumors which grow from the larger biliary tubes. If the closure is not complete so that bile passes into the intestines, the diagnosis is difficult. If complete, hypertrophic cirrhosis may be excluded with considerable certainty.

The question naturally arises, why is there jaundice in hypertrophic cirrhosis if the ducts are patulous? Charcot's theory that this trouble consisted essentially of a disease of the biliary radicles has been disproved. Rosenstein has suggested that there is an over-secretion of bile and a lessened excretion through the smaller tubes but this theory does not solve the problem. Dr. Freghan believes that Charcot's theory is in part correct, that some of the biliary passages are involved so that bile is reabsorbed into the blood while other biliary passages are normal and excrete bile into the intestines.

With regard to ætiology, Dr. Freghan adheres to the old view that alcohol is an important factor. He also inclines toward the belief that there may be a tubercular element. At any rate, hypertrophic cirrhosis and pulmonary diseases—especially tubercular—are frequently united in the same patient.

NEURALGIA OF THE TRIGEMINUS.

Dr. Leslie (*Lo Sperimentale*, No. 21, 1891) recommends snuffing a pinch of common salt into the nostril of the side affected, or throwing in a solution by means of a spray.

THE DIAGNOSIS OF SOME ABDOMINAL TUMORS SUPPOSED TO BE OVARIAN.*

By JAMES A. GOGGANS, M. D.,

ALEXANDER CITY, ALA.

Our text-books often lead one to believe that it is quite an easy matter to differentiate between ascites and abdominal tumors, and I have recently noticed that a few writers have, in referring to their series of abdominal sections for various causes, stated that, "no mistake in diagnosis was made in the whole series."

Now, my experience does not lead me to believe that the diagnosis of abdominal tumors is always such an easy thing; and I will make a few remarks on cases which have occurred in my experience which will serve to illustrate the fact that the diagnosis is often difficult, and in some cases indeed, quite impossible without resorting to an exploratory incision.

The specimen which I hold in my hand, is a part of the remains of a cystic ovary and tube removed from a patient, 35 years of age. She was taken with pains in the pelvis after having had her fourth child. This pain continued for four years before the abdomen began to enlarge, and at the time I saw her and removed the tumor the abdomen was extremely large. She had been tapped three times and large quantities of fluid had been withdrawn. The canula had been left in the abdominal cavity for three days, and a solution of iodine had been injected into a cyst which was supposed to exist. I recognized some obscure form of pelvic disease and opened the abdomen for its removal. Two water buckets-full of ascitic fluid escaped from the abdominal cavity, when a cystic ovary as large as an orange was found floating in the pelvis. The cyst was ruptured in the attempt to bring it through the abdominal incision, the pedicle being extremely short. There has been no return of the dropsy, and the patient has made an uninterrupted recovery.

The following case is one of extreme interest, being the only case which has ever recovered in America after operation, and perhaps the only one where operation was

*Read (by title) before the Georgia State Medical Association April 22, 1892,

undertaken for exactly the same condition in this country.

Patient, 21 years of age, had been in bad health for two years, but her abdominal pains had existed only about eight or ten months. The abdominal enlargement was first noticed only three months before I first saw her. Her father and brother, both physicians, had made the diagnosis of abdominal dropsy, and upon my first examination I thought that I had to deal with an ovarian cyst. Upon further investigation I recognized some obscure form of abdominal cyst which could be elucidated only by an exploratory incision. This was made and the cyst proved to be one of the mesentery. The removal of the sac was impossible, consequently it was incised and emptied of a large amount of thin fluid, the incised lips drawn into the abdominal incision, and a glass drainage tube introduced to the bottom of the cyst and drainage kept up until recovery was complete.

The second specimen I show you is a multilocular cyst of the ovary. It was removed from a patient, 45 years of age. The abdomen was quite full of ascitic fluid, and fluctuation in the cyst was very indistinct. In fact the fluid in the cyst was only semi-fluid. The diagnosis in this case was almost impossible. From the fixity of the tumor it seemed to be a most unfavorable case on which to operate; but there was much distress, and as the uterine cavity was not elongated, and there were no other signs indicative of malignant disease, I consented to operate, with the results as I show you. The patient made a perfect recovery.

A few weeks ago I was asked to see a lady who had been told that she was pregnant, and the symptoms pointed very clearly toward pregnancy, the menses having ceased to flow quite suddenly. It turned out to be a dermoid cyst which in all probability may have been solid originally, and very closely connected with the uterus. I must think that all abdominal surgeons who have much experience encounter more or less difficulty in the diagnosis of many cases. And I believe that we should exhaust every means at our disposal to make a perfect diagnosis, but after doing all this, there are still cases where there is manifest serious abdominal disease, and our course is quite clear that we should not wait for a post-mortem examination to clear the way, but should boldly make an exploratory incision and give the patient a chance for life. I can recall cases sufficient to establish in my mind the fact, that many lives may thus be saved, which would, without exploratory incisions, have been sacrificed. I make it a rule to regard all female patients, who are invalids and suffer from incapacitating pains, with surgical suspicion, whether they have a tumor or not. If I can not make the diagnosis perfectly clear, it in no way interferes with me, for I believe the way to duty is quite clear, and that the condition is an unnatural one and demands an operation. I am not an advocate for abdominal section for mere symptoms, especially dysmenorrhœa and the neuroses, but am firmly of the opinion that we should always be able to put our hands on something that we know is pathological, and is causing serious symptoms, before we subject the patient to such a grave procedure. The point I wish to bring out in this paper is, that it is altogether unnecessary to wait and try to map out all of the pathological conditions that may be present in a given case before an operation is undertaken.

RESECTION OF THE INFERIOR MAXILLARY NERVE.

Dr. v. Vamossy reports a case treated by Zuckerkandl's method and describes the operation as follows: "The incision is mada on a line drawn from the tragus to the middle of the naso-labial fold, so that one-third of its length is over the masseter and two-thirds in the cheek. Cautiously dissecting down to the fascia of the masseter, Steno's duct and the facial nerve are to be drawn aside. After the moderate hæmorrhage has ceased, the fascia is opened and the fat removed with forceps and scissors. There is now a cavity, whose bottom is the buccinator, and which is bounded behind by the internal pterygoid and without by the masseter muscle, the ascending ramus of the jaw and the tendon of the temporal muscle. At the posterior part of the latter the nerve is found. It is easiest found by tracing back the branch which is found at the bottom of the wound upon the buccinator muscle. From 2 to 2½ cm. of the nerve should be excised. V. reports a successful case. The only drawback of the operation is its bad cosmetic result."—*Wien. Med. Presse*, No. 48, 1891.

THE ÆTIOLOGY AND BACTERIOLOGY OF DIPHTHERIA.*

By FRANKLYN J. TOWER, M. D.

MILWAUKEE, WIS.

Although this is a subject which is causing a great deal of discussion in the medical world and so much is at present written on it, I have no apology to offer for reading this paper before the Milwaukee Medical Society. The particular point I wish to elucidate and emphasize most strenuously is the examination of all membranes or other exudates in cases of suspected diphtheria and to show the ease with which it can be done by any physician possessing a microscope of four or five hundred diameters magnification and a few modest accessories which should be in the appanage of all practitioners of medicine.

There is probably among the diseases which we are called upon to treat, none more difficult to diagnose than diphtheria; and when we fail to recognize it, in no instance are the consequences likely to be more disastrous to others exposed. On the other hand, when every case of throat difficulty is called diphtheria and treated accordingly, there is an unnecessary isolation, an unnecessary expense both to the government and patient and with but one possible advantage; praise for the doctor upon the rescue of his patient from the grave. On this so-called advantage I think you will agree with me when I inform you that in 880 cases which have come under my indirect notice I find that 50 per cent. recover within 48 hours: and if this is diphtheria it is a disease of most benign type and instead of dreading to care for cases we should delight in a disease with such a termination.

Several have put forth the assumption that filth was the direct cause of diphtheria but all such theories have long since been exploded.

In 1868, Oertel discovered in the diphtheritic exudate a micrococcus; Cohn also found them and called them micrococcus-diphtheriticus; but Billroth, Klebs and others showed them to be the pyogenic bacteria which without doubt we find in a large per cent. of all throat affections and which if in sufficiently large numbers will produce grave and general toxæmia, but such conditions are not contagious and in no case does paralysis follow, and we have usually a rapid convalescence. The pseudo-diphtheria described in which a claim is made that a non-toxic bacillus identical with the Klebs-Loeffler bacillus (to be later described) is found, is probably a pyogenic micrococcic disease with occasional bacilli, for I have failed to corroborate the assertion and believe that there is but one diphtheritic germ and as Roux and Yersin hold that the other bacillus found by some investigators is but an attenuated form of the Klebs-Loeffler bacillus, there being but one thing which may argue against this, i. e., the Klebs-Loeffler bacillus changes the alkaline reaction of the culture media to acid while the spurious bacillus does not.

In 1883 Kelbs isolated a peculiar bacillus always present in diphtheria, conducted many experiments upon it which were verified by Loeffler in 1884 and later by Brieger and Frankel, Roux and Yersin, Simonds, Klein, Welsh and Abbot and many others.

Osler states in his late and very excellent work on practice that the poison of diphtheria is not given off by the breath; but owing to many instances of infection through the air only, with which I am cognizant, I cannot agree with him for I have also been enabled to infect tubes of media with the breath from a diphtheritic blown through a glass tube bent many times, so that fluid particles could not reach the culture media.

To Wagner, Weigert and Oertel are we indebted for the descriptions of the minute changes which take place in diphtheria, the always perfect technology of Weigert showing itself in every case.

Klein, of London, in 22 cases of diphtheria found the Klebs-Löeffler bacillus in all and in those examined in which they were not found the cases were not contagious and recovered rapidly.

V. Bates found with no exception the bacilli in all cases examined.

In the series of 342 cases compiled by Johnston, of Montreal, examined by sixteen different men, 307 cases were found in which the bacilli were present, 35 cases absent, 24 of these were of Dr. Prudden's cases; and it is well here to notice that these were all cases of sore throat of chil-

*Read before the Milwaukee Medical Society, May 24, 1892.

dren, all inmates of an institution in which there was an epidemic scarlatina and erysipelas, so that these should go for naught. The other eleven cases were instances of one or two failures in a large series, as in 52 cases examined by Beck, in two of which he failed to discover the bacillus.

Ruffer in the *British Medical Journal* in a preliminary paper on this subject gives many interesting notes on examination, and also some good staining processes. Simonds in an elaborate article remarks that every false membrane which does not contain the Klebs-Loeffler bacillus is not a diphtheritic product, and writes very exhaustively on the morphology of the organism. In the experiments on animals, of Roux and Yersin, the important fact is disclosed that the bacillus can be found as early as six to fourteen hours after the inoculation, and it is well known that in a 24 hours culture, the bacilli will have developed so that they can be seen in colonies and on steamed potato show the characteristic thin, colorless, glassy scale. It might be well at this point to call your attention to the description of the bacilli under consideration; they are about the length of the tubercle bacillus and twice as thick, that is, about 3μ in length by 6μ in thickness; they exhibit a variety of bizarre and various forms; are often thickened upon one or both ends; in which latter case the central tenuity may be nearly invisible, giving the appearance of a diplo-coccus, and may be sometimes bent like a comma baccillus. They are stained in two minutes in solutions of the methyl blues, or in 15 minutes by Gram's method; they grow well on gelatine bouillon, blood serum, steamed potato, or in sterilized milk, are killed by an exposure to 58° temperature for ten minutes, do not grow, except sluggishly, at a temperature below 18°; they form no discoverable spores, but are extremly tenacious of life, as they may be dried for years and then recover and show their vitality upon implantation in a proper soil; they form an exceedingly active toxalbumin.

In 1890 in one of the numbers of the *Berliner Klinische Wochenschrift*, Brieger and Fränkel give an exhaustive article on ptomaines or bacterial poisons, as they designate them, and give many experiments of the filtered cultures of the Loeffler bacillus. According to their researches, the ptomine is rendered innocuous by exposure to a temperature of 100° for twenty minutes, or two hours at 58°; when injected into animals, caused multiple cell necrosis and paralysis, but no membrane: the actual presence of the bacilli themselves being necessary for the formation of the exudate; the paralysis even occuring after many weeks.

In 1887 Loeffler made the first experiments on this ptomaine by making ether extractions of bouillon cultures and evaporating to dryness, dissolving the residuum in water and making from the resultant solution the inoculations.

According to Roux and Yersin the ptomaine introduced into the stomach causes little trouble; alcohol precipitates it from solution; carbolic acid has also the same property and a small amount added to cultures diminishes their toxicity.

The bacilli are found only in the most external portions of the membrane so that on section and proper staining the bacilli can be seen confined only in that part of the membrane.

This exudate consists of an aggregation of dead cells most of which have become hyalin material; and the nuclei when seen have suffered a fragmentary destruction. The first change which takes place when the bacilli have fallen on a proper soil is a cell necrosis caused by the ptomaine, particularly of the epithelium and leucocytes which become paralyzed and are unable to perform their function of phagocytosis. The irritation causes an exudation of fibrin elements agglutinizing the whole together and the pseudo-membrane has now a layer: and it is thus that there are many layers formed which can be seen by placing a diphtheritic exudate in water when the layers will separate. Following the cell death a hyalin transformation or coagulation necrosis occurs.

At a late meeting of the Berlin Medical Society a lengthy discussion was called out by a paper read by Baginsky on the ætiological relationship of the Klebs-Loeffler bacillus to diphtheria in which the important and general decision was reached that an absolute diagnosis of diphtheria could not be made without a bacterological examination. In 154 cases of so-called diphtheria, Baginsky found the Klebs-Loeffler bacillus in 118, the mortality of which was 40 per cent; only 25 per cent. ran a mild or favorable course; of the 36 cases in

which only cocci were found, only four proved fatal or 11 per cent.; and one of these was complicated with measels and died from pneumonia; two developed bilateral empyema and the other was admitted with a severe paralysis, in which latter case the bacilli had probably given way to the coccic invasion and it was a true case of diphtheria; which would give but a mortality of 8 per cent. in the coccial variety, if I may be allowed the term; and they all developed sufficient complication to prove fatal.

I have six cases which I desire to refer to, all of which have come under my notice in practice. Case one: female, age 18—all the symptoms of diphtheria; exudate covered both tonsils extending back over the entire pharynx, no bacilli found, and on this result called it a tonsilitis—other children were exposed who had not had diphtheria—case recovered in three days and the other children remained well.

Case two: Female, age 7, small patches on right tonsil and uvula, very light case, bacilli present, child isolated but brother came down in a few days.

Case three: Male, age 11, brother to case No. 2, membrane very extensive, great prostration, bacilli found, faucial paralysis developed and remained for a long time.

Case four: Female, age 10, contagion from sister who died three days previous to my being called, membrane extensive, nasal and laryngeal variety and extended as far down as I could see, bacilli very numerous.

Case five: Male, age 6, disease infecting the nose principally, uvula slightly affected, many bacilli present, exposed to child of neighbor who died.

Case six: Female, age nine, membrane extensive, bacilli present both in exudates and in a piece of expectorated membrane, nasal voice and difficulty in swallowing remained for some time.

I have examined all cases of throat disease that have come under my notice and when the bacilli were found I had many reasons also for believing my case to be diphtheria, and when not present I have never seen contagion follow, any paralysis, or even slow convalescence. My method is as follows in these cases—I carry a few cover glasses on my second visit, take two or more, clean them, rub a little of the tonsilar, faucial or nasal exudate on them or put a particle of the membrane between two and press it out flat—slide the glasses apart and dry for 2 or 3 minutes in the atmosphere, put covered glasses together and return wrapped in paper to my pocket until my return home—when in a few minute I find, or not, the bacilli: often times there are micrococci of many kinds and spirilla; even the leptothrix found in the mouth is often seen, but no trouble will be had in seeing and determining the proper bacilli. When the disease has progressed and the Kelbs-Loeffler bacilli are present in considerable numbers they are nearly if not quiet alone. In all cases of suspicious throat difficulties it is well to examine with a view to the determination of the presence of the bacilli. In Case I. which I recited, as in many others which I have seen, I was inclined to call it diphtheria on my first visit, but did not solely because I failed to find the bacilli, and though others were exposed to the case no contagion followed.

I must of necessity arrive at the conclusion that a microscopical examination of membrane or exudates is of much value in the diagnosis of this disease.

A few words on some of the late experiments with the chemistry of the toxalbumins of diphtheria or albumoses as they are now called, will no doubt hold attention. Injections in animals of minute doses produce a Wallerian degeneration of certain nerves, seeming to be greater in motor nerves and to affect particularly the terminals; alternate fibrils are attacked, accounting for the recovery from diphtheritic paralysis, we have therefore in this substance not only a fever producer but a true nerve poison.

By making extracts of the tissues of a corpse dead of diphtheria, doing so within a few hours after death to preclude the entrance of saprophytic bacteria, not only can a toxalbumin be removed, but also an organic acid which has far less virulency when inoculated into animals. These albumoses are precipitated though not coagulated by alcohol, are soluble in water and not precipitated therefrom by ebullition.

According to Roux and Yersin, .0004 gm. is capable of killing 8 guinea pigs of 400 gms. weight each, or two rabbits of 3 kilo-grams each.

Martin concludes that the effect of this poison in the body is a digestive process;

the proteids of the body upon digestion forming these albumoses and organic acid. In anthrax we have an alkaloidal poison; in diphtheria it is probably a ferment. (For discussion, see Society Reports.)

110 Mason St.

SOME POINTS CONCERNING THE OPENING OF THE MASTOID PROCESS.

Heiman (*Arch. of Otol.*, xx, 2) sums up the indications for the operation as follows: 1. In acute purulent otitis media, complicated with inflammation of the mastoid process, when the inflammatoy symptoms do not yield to antiphlogistic treatment and Wild's incision. 2. In acute and chronic purulent otitis media, when the escape of the secretion is impeded by granulations in the middle ear or stenosis of the external auditory canal, or when there is a suspicion of inflammation of the mastoid process. 3. When the mastoid process is apparently healthy, but the removal of pus or cholesteatomatous masses through natural channels is impossible, and symptoms dangerous to life manifest themselves. 4. In congestive abscesses and fistulas in the region of the mastoid process. 2. In persistent, continuous pain in the mastcid process, yielding to no other treatment, especially when it seems sensitive to pressure. 6. As a prophylactic operation, in symptoms of retention of secretion and inflammation of the mastoid process when death is to be feared on account of imperfect disinfection. 7. In acute purulent otitis media, in which there is no inflammation of the mastoid process, and no retention of secretion, but in which the discharge is very profuse, does not yield to the usual methods of treatment after a certain time, or even increases. 8. When there are distinct symptoms of inflammation of the brain and the meninges.

Heiman has used the trephine *á crèmaillière* of Pasteur for opening the mastoid, and has received the following impressions from its use: 1. The removal of the compact portion of the mastoid process is much more rapid than with the mallet and chisel. 2, The edges of the wound need not be rendered smooth after the operation. 3. The different size of the trephines permits the formation of a wound in the bone of the desired size. 4. Shock is entirely obviated. 5. The depth of the wound can be graduated with exactness.

Society Reports.

MILWAUKEE MEDICAL SOCIETY.

Stated Meeting, May 24th, 1892.

Dr. F. J. Tower read a paper on the Ætiology and Bacteriology of Diphtheria. (See page 181.)

DISCUSSION.

Dr. Miles H. Clark: I have very little to say in opening this discussion, except words of commendation for the paper of Dr. Tower. I do not think that there can be any doubt in the minds of any of us as to the advisability of microscopical examination in order to determine a doubtful case. As far as I myself am concerned, I have been singularly fortunate, in having but one case of diphtheria since I have been in the city, but I have had any number of cases of tonsilitis and cases doubtful enough in my own mind so that I have been rather suspicious and at certain times anxious, for fear that contagion to other members of the family might follow; and it seems to me that with this method before us, properly carried out, that many times, not only the lives and safety of other members of the family can be cared for, but also the extreme annoyance to the members of the family itself from having a case placarded which is not diphtheria avoided; and I have no doubt that very many cases have been thus reported which were not diphtheria. I have seen many cases of tonsilitis with the tonsils completely covered with membrane from the coalescence of distinct follicles or follicular patches, which have recovered in the usual short time of a tonsilitis; but if such case as that had furnished contagion for a family of four or five children, and had resulted in diphtheria to the rest of them after I had called it tonsilitis, I might have felt very much ashamed of myself. For this reason I would simply commend the examination of the exudates in this manner.

Dr. F. E. Walbridge: I would like to have the doctor give us his methods of staining the bacillus.

Dr. A. B. Farnham: The infecting poison is a ptomaine. The bacillus forms a slight layer and the ptomaine causes the fever, as I understand it. A practical

question came up to me once this summer. If you will notice at the commencement of the disease, you will see a first glassy layer and if you treat that layer with a solution of chromic acid of sufficient strength and penetration to destroy it, could not the case be cured? The only case of diphtheria that I have treated in a family here in Milwaukee was one in which I saw that very first infection, a small, glassy layer. I happened to be treating a throat disease and it developed this, and on just that merest commencement I made a diagnosis which proved to be correct, and I have thought since that if that had been destroyed then and there, the whole difference might have been ended. Once this summer I saw that same appearance and I did treat it with chromic acid and it was the end of it.

Dr. S. W. French: We might as well tell of our failures as our successes. It will be remembered that a few weeks ago I reported some possible cases of abortion of diphtheria by the use of submucous injections of chlorine water. It was not very many days after that when I was called to a case that had undoubted symptoms of diphtheria, and I gave it a most thorough injection, and I used chlorine water that there was no doubt about whatsoever. There was some doubt, I will say, in regard to the other cholorine water that I used after I had seen this. I gave that case an injection on two successive days and gave it very thoroughly, but the case went from bad to worse and is now under the sod. Dr. Tower made the statement that the bacilli were found on the surface. Seibert, however, in his paper in the matter of the use of chlorine water, says that the bacilli are found in the sub-mucous layer and that is the reason he gives them the submucous injection of chlorine water, to kill the bacilli in their nest holes, so to speak.

But there is one other point. Dr. Tower has said in his paper that it is, as I understand it, beyond a doubt established, that this so-called Klebs-Löeffler bacillus is the bacillus of diphtheria. I should like to know if that is a positive fact; if it has been proved over and over again a sufficient number of times to establish beyond a doubt that it is the bacillus of diphtheria.

Dr. W. H. Washburn: From my reading, it has not seemed to me as though the question of the ætiology or the materies morbi of diphtheria was yet absolutely determined, although especially during the last two or three years the evidence seems to be growing stronger and stronger that the Klebs-Löeffler bacillus is the materies morbi of the disease, yet if you will look over the files of the medical journals, you will find that a great many cases are reported that have presented all of the appearances of diphtheria, both as to the course and termination and following paralyses, and many cases also with the element of contagiousness present, where this peculiar bacillus has not been found.

Dr. Tower referred to the cases of Baginski. The impression that I derived from reading the report that I saw of that paper was somewhat different from the way he stated it in his paper. There were quite a number of cases that presented every appearance of diphtheria except that they did not contain these bacilli; and a certain number of those were fatal and were followed by paralysis of the pharynx, and I believe that those cases were cited to illustrate the fact that it was not so certain after all that the Klebs-Löeffler bacillus was the actual active agent in the disease; nevertheless the mortality among those cases was much less than among those in which this bacillus was present.

I think that we would gain considerably if we were all of us expert enough with the microscope to be able to recognize these bacilli; but I do not think that if I had Dr. Tower's paper as a guide and my microscope beside me that I would be able to make a satisfactory examination of the sputum. It does not seem to me as though he has gone sufficiently into the subject of the preparation and characteristics of the bacilli to enable one who is not already expert in the study of bacteriology, to the discovery of this bacillus.

Dr. A. J. Puls: I just want to make this point, that Dr. Tower stated that contagious diseases of the throat he classes always as diphtheritic. It seems to me that I have seen a number of cases of ordinary tonsilitis which was just as contagious as diphtheria, although the disease appeared in a benign form; so also coriza.

Dr. U. O. B. Wingate: It is well known that we have a great deal of diphtheria in this city. During the past year 1891, there were four hundred deaths recorded, and usually where a death certifi-

cate comes in, it is pretty sure that the diagnosis has been correctly made as diphtheria. Undoubtedly there are a great many cases of diphtheria reported that are not diphtheria, but I think that the physicians of the city as a rule are inclined to give the public the benefit of the doubt and report the cases. It is a commendable practice, I believe, and unless there is some way of making a positive diagnosis, as Dr. Tower has stated in his paper, it seems to be the best course to pursue. Certainly it is much better to report a case that is not diphtheria than it is to fail to report a case that is genuine diphtheria, if we are to attempt to do anything in the way of prevention. There are certain wards of the city, I have noticed in looking up the records of the past year, that show a very marked dissimilarity in the proportion of the number of cases reported and the deaths. Some wards show a very large mortality compared with the number of cases reported and others a very small mortality.

There are two questions I would like to ask Dr. Tower, one is, is it not well recognized that you may find bacillus of diphtheria in a throat that does not have diphtheria and which may recover without having diphtheria, or even in perfectly healthy throats? The other question is in regard to the degree of temperature which will destroy the bacillus, which I do not quite understand?

Dr. F. J. Tower: In answer to Dr. Walbridge about the staining of these bacilli, there is probably nothing easier to do in a microscopical way. All the necessary chemicals that are needed are a small amount of a Methyl blue, probably Grieber's blue is about the best that can be had; it can be made in an aqueous solution, or it can be made in what they call Löeffler's blue which is an extremely weak solution of caustic potash with the aniline dye dissolved in it, making a saturated solution in alcohol; and when you want to use the staining material add five or six drops of the saturated alcoholic solution of the aniline to a watch-glass full of water; pass your slide through an alcohol-flame or gas-jet two or three times to set the albuminous substances, then place it in your watch-glass of blue water and hold it over the burner or gas-jet and heat it until it steams; do that for two or three minutes or until you bring it to the boiling point, then let it stand for four or five minutes; take the cover-glass out of the blue solution, wash it in water, put it proper side up on a slide and examine it immediately, pressing out the superfluous water. Probably there is no easier thing to do than to make that examination. If you are in doubt as to the presence of the bacillus, take a potato, which need not be sterilized, put some of the exudate on it and keep it at about the temperature of the body, about thirty-eight degrees; leave it there for five or six hours or until the next morning, then take a little of this glassy film which forms. The Klebs-Löeffler bacillus under proper temperature grows with extreme rapidity, whereas other bacteria that would interfere with our examination do not, so that it is really unnecessary to sterilize the media that we use for examining or hunting for the Klebs-Löeffler bacillus,

In answer to Dr. Farnham about the the ptomaine, as I understand it, I think the definition for the word ptomaine means alkaloidal-poison. According to the late experiments made with this substance produced by the Klebs-Löeffler bacillus, it is not a true ptomaine, it is an albuminous substance. This glassy layer that the doctor spoke about is exactly what is seen on a potato or on gelatine. The finding according to Seibert of the bacilli in the submucuous tissue I doubt. I have made lately some sections of diphtheritic membrane according to new processes and find that the bacilli are with possibly an exception or two, all contained in the outside, so that if we take a piece of membrane say one-eighth of an inch thick and properly stain it, when it is thoroughly washed out and held to the light, we will see a fine blue line in some cases where the bacilli are; oftentimes they do not seem to be able to puncture through the membrane. Otherwise, why do not the bacilli enter the body, and it is a known fact that they do not. As far as the Klebs-Löeffler bacillus being the cause of diphtheria is concerned, I did not know that there was any doubt about it, but there may be. As good men as I have quoted in my paper, men that are continually working on that subject, almost no other subject, claim that it is a fact. My own experience has been limited; I have had a very few cases to examine actually, but in those cases where I have, as I state, I found the Klebs-Löeffler bacillus,

and where it was a case that had progressed considerably there were no other bacteria found at all.

Dr. Washburn said that he had a different idea from a certain paper by Baginski. Baginski did in his article call out both sides of the question. My reference to that paper was only in this way, to the opinion of the other men present who were probably at this meeting in Berlin lately, some of the most eminent men there are in the world, and the general opinion arrived at seemed to be that a bacteriological examination was necessary, as I stated.

In regard to not being sufficiently plain in my methods, I think I have covered that point now. About the contagiousness of choryza and tonsilitis, that certainly is possible; but the contagion that we have there as due to the streptococcus and the cephalococcus pyogenus due to pus microbes. I think Dr. Weurdemann will tell you, as I believe, that some cases of otitis media are contagious, and probably for the same reason. Dr. Wuerdemann, could not such a case of otitis media produce an ophthalmia?

Dr. H. V. Wuerdemann: Yes, sir. Otitis media, however, is contagious indirectly, i. e., the nasal affection disease is contagious; and coryza is contagious, producing a purulent ear disease, then eustachian salpingitis, and after that, middle ear disease.

Dr. Tower: In answer to Dr. Wingate about finding the Klebs-Löeffler bacillus in non-diphtheritic cases, I doubt if it is so found. It has been to my mind proven, where there is a considerable number of Klebs-Löeffler bacilli present, the substance which they produce being a ferment, a minute quantity of it in the circulation seems to act as ferment, and that minute quantity it is necessary to have but a very small number of Klebs-Löeffler bacillus present to produce, so that if we had a case with any discoverable number of Kelbs-Löeffler bacilli in the throat, we would probably have some systemic effects also. I believe that some investigators, I could not name them now, have claimed that they found occasionally the Klebs-Löeffler bacilli in sputum, in faucial mucous, but there is, of course, in those cases where you find one or two, the possibility of not only their inability to discover them, but also it is very easy to make a mistake in the bacteriological examination, if everything is not absolutely and scrupulously clean, in which case you are bound to have some kind of outside infection.

In regard to the temperature necessary to destroy the Klebs-Löeffler bacilli, probably it was a little bit misleading, as I used the centigrade scale. Exposure at a hundred degrees or boiling point is sufficient to destroy them. The Klebs-Löeffler bacilli themselves grow but very sluggishly at a temperature below 18 degrees centigrade and do not grow above 58 degrees centigrade which would be about 140 degrees Fahrenheit.

Dr. A. B. Farnham: I believe that the authorities state that an exposure to a temperature of 140 degrees for ten minutes will destroy the Klebs-Loeffler bacillus; of course a higher temperature is usually employed, 200° or 250°.

Dr. W. H. Washburn: The doctor spoke of the bacillus being present on the surface of this false membrane, and in his remarks he said—at least I so understood him—that if the bacillus was on the under surface of this false membrane, why didn't it get into the blood. We know that these bacilli do not get into the blood. Is it not a fact that these bacilli have been injected subcutanously under the skin of the animals and yet have not got into the blood? If I am not very much mistaken, experiments of that kind have been repeated time and again. The bacilli have been injected subcutaneously and still have not found their way into the circulation, but remained right where they were injected; and hence the objection that the bacilli were not on the under surface of the membrane, because they did not get into the blood, would not be tenable.

SEPSIS OF THE UMBILICAL WOUND.

Eross (*Arch. f. Gyn., B.* xii., H. 3) observed the process of healing of the umbilical wounds in 1,000 new-born infants under different modes of treatment. A strictly normal course was the exception rather than the rule. Morbid conditions of greater or less gravity were found in sixty-eight per cent. These consisted in sloughing of the stump, softening instead of complete mummification, decomposition of fragments left undetached after the rest had separated, suppuration and gangrene. Pyrexia occurred in 220 cases and in a certain proportion of instances was the only evidence of septic absorption.

Selected Formulæ.

FOR HOARSENESS.

In addition to the measures employed in the treatment of the causative condition, the following formula will prove useful in the amelioration of hoarseness:

℞ Acid. tannic.....3j.
Pulv. sodii biborat.....3j.
Tinct. capsici .....f3ss.
Aquæ rosæ.....f3x.—M.
S.—To be used frequently as a gargle.

—*Whitla.*

FOR LARYNGEAL PHTHISIS.

In the treatment of this affection, Cozzolino (*Revista de Ciencias Médicas de Barcelona*, April 25, 1892) employs this mixture:

℞ Pulverized iodoform..... 5 00 grammes.
Powd. phosphate of calcium.10.00 grammes.
Boric acid, in powder..... 5.00 grammes.
Menthol.. .....From 40 to 80 centigrammes.
M. Sig.—To be insufflated into the larynx, night and morning.

FOR SYPHILIS.

The following mixture is recommended by Stukovenkoff and Balzer (*Jour. des Maladies Cutan. et Syphlit.*, April, 1892), in the treatment of syphilis:

℞ Benzoate of mercury..... 0.40 gramme.
Iodide of potassium..... 20.00 grammes.
Distilled water..... 25.00 grammes.
Simple syrup..... .....1000.00 grammes.
M. Sig.—A dessertspoonful a day.

THE USES OF RESORCIN.

The therapeutic uses of resorcin are carefully reviewed in *Il Raccoglitore Medico*, April 30, 1892, and the following prescriptions recommended:

For *acute gastritis, dyspepsia, etc.*

℞ Pure hydrochloric acid.
Sublimated resorcin, of each.... 2.00 grammes.
Syrup of orange peel..... 20.00 grammes.
Distilled water.....178.00 grammes.
M. and place in a dark bottle. Sig.—A tablespoonful every two hours.

For *catarrh of the stomach:*

℞ Infusion of rheubarb root .....180.00 grammes.
Sublimated resorcin..... 3.00 grammes.
Bicarbonate of sodium..... 8.00 grammes.
Peppermint water..... 10.00 grammes.
M. and place in a dark bottle. Sig.—A tablespoonful every hour.

For *carcinoma of the stomach:*

℞ Decoction of condurango.....180.00 grammes.
Tincture of rheubarb..... .... 5.00 grammes.
Sublimated resorcin..... 2.00 grammes.
Syrup of orange peel..... 20.00 grammes.
M. and place in a dark bottle. Sig.—A tablespoonful every hour.

For *sea-sickness:*

℞ Sublimated resorcin.....0.1 to 0.75 gramme.
Sugar of milk.....0.5 gramme.
M. and make thirty papers. Sig.—A powder every hour.

EARACHE.

When due to inflammation of the external meatus, it is well to scarify first, and then to make use of aural suppositories or tampons, about one-third inch long, and composed of:

℞ Morphin. sulph.
Cocain. hydrochlor.....āā cgm. 10.
Gelatin.....grm. 90.—M.

Or, the canal may be irrigated by 6-per cent. solutions of cocaine, or 20-per cent. solution of carbolic acid in glycerin.

—*Giornale Internatz. delle Scienze Med.*

CAVAZZANI'S ANTISEPTIC POWDER.

To improve upon the antiseptic virtue of iodoform and at the same time to diminish tendency to cause bleeding, Cavazzani (*Wein Med. Presse*) has devised the following:

℞ Iodoform .....P. 55.
Salicylic acid.....P. 20.
Bismuth subnitrate.....P. 20.
Camphor ..... 5.

This mixture has proven an excellent disinfectant and stimulant in cases of bubo. Its use must be suspended every fifth or sixth day, iodol being employed instead.

SUPPOSITORIES OF MORPHINE AND COCAINE IN PERITONITIS.

Dr. Klefer (*Le Bulletin médical* No. 44, 1892), in order to combat the pain and vomiting of peritonitis, employs the following suppository:

℞ Extract of opium..... } āā cgms. 6.
Hydrochlor. cocaine ..... }
Iodoform ..... } q. s.
Cacao butter..... ....}

NUTMEGS IN HÆMORRHOIDS.

The common nutmeg employed in the form of an ointment is said to give prompt and permanent relief in itching and painful piles. It may be employed as follows:

℞ Pulv. nuc. moschat.....3ij.
Acid. tannic.....3j.
Petrolat .....3j.
M. Sig.—Apply locally.

—*Ex.*

CORYZA.

℞ Naphthalin in an impalpable powder..3vj.
Powdered boric acid.....3vj.
Powdered camphor.....gr. xv.
Extract of violets.....gr. xv.
Essence of roses.....gtt. xx.
Sig.—Mix and use as a snuff in coryza.

—*L'Union Médicale Therap. Gazette*, May 16, 1892.

THE

MEDICAL and SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

DIRECT COMMUNICATIONS TO

P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor.

(Professor of Physiology, University of Penna.)

BUSINESS OFFICES:

29 to 35 North Tenth Street, Cor. Filbert.

EDITORIAL OFFICE:

Southeast Cor. 36th and Woodland Ave.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00

REMITTANCES should be made payable to THE MEDICAL AND SURGICAL REPORTER, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

—o—

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates).... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt "**The Medical and Surgical Reporter**" and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts.....$1.50 each.
Bovine Points or Quills..... 1.00 a doz.
Humanized Crusts..... 1.00 small.
Humanized Crusts..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

☞Please accompany orders with the money, and address all communications to

Leading Articles.

CARBOLIC ACID GANGRENE.

The profession has recently been warned more than once through the unfortunate experience of surgeons that the use of carbolic acid solutions as a surgical dressing is frequently followed by grave complications, amounting in some cases to a condition of dry gangrene of the parts that have come in contact with the acid. This complication may result when the original injury is only trivial. The first symptom the patient will complain of is a numbness of the parts, or a prickling sensation, this is frequently followed by severe pain, and upon removal of the dressing the parts below it will be found to have assumed a dark blue or black color, to be without feeling, and in other words, to present the typical picture of dry gangrene.

Billroth, the German surgeon, has some time since called the attention of the profession to the danger attending the use of carbolic acid, and his warnings were quoted by nearly all the leading German medical journals. Strange to say, apart from the histories of a few cases published by Kortum, no further mention has been made of the subject in German literature. Kortum sought to explain this unfavorable action of carbolic acid, by crediting it to an action upon the vaso-motor nerves.

It has however, been the privilege of Dr. A. Frankenburger, of Nurenberg, in his able Inaugural Address before the University of that city, to definitely settle the question of the cause, and to throw much valuable light upon the subject. His address has also been discussed editorially in a recent number of the *Medicinische Neuigkeiten.*

In France the subject has been widely discussed, and among French writers on the subject the dissertations of Tilleaux and Secheyron are perhaps most notable. It is evident that the conditions produced

are not merely the result of the cauterizing effect of the acid, as suggested by Billroth.

Frankenburger, to settle the question, conducted a series of experiments upon animals, the results of which appear to be most conclusive. He applied the acid in the form of a 3 per cent. or 5 per cent. solution upon a bandage covering the intact skin of the animal. The parts over which the bandage was placed were shaved, and the dressing kept constantly moist with the solution. Every half hour microscopical examinations of a portion of the skin were made, and the experiments lasted for about three hours in each instance.

In every case a typical "mummification" of the skin was observed, which gradually encroached upon the deeper tissues the longer the application was continued. The microscopical appearances of the preparations were very characteristic and similar in every case.

The epidermis was destroyed, and the papillæ of the chorium were laid bare; there were large gaps in the connective tissue due to an enlargement of the lymphatics; the lumina of the vessels were filled with a partly yellowish red and partly yellowish white masses,—viz., vascular thrombi.

That these thrombi are really formed *intra vitam* during the course of the experiments, is proven by the results of many authors who have studied the action of carbolic acid upon the blood, among whom we may mention, G. G. Bill, Huchs, Prudden and Hueter. These writers have observed as an action of the acid a change of the blood corpuscles, consisting in a degeneration of the red corpuscles and accession of the amœboid movements of the leucocytes. This has been shown by direct examination of the mesentery of a curarized frog, as a direct action of the acid. Frankenburger's experiments show that a similar action is obtained by the mere application of dressings moistened with a weak carbolic acid solution. He summarizes the results of his experiments as follows:

If parts of the human body, intact or else having slight injuries, be brought in contact with a carbolic acid solution of 2½ or 2 per cent. strength, the action of the acid will in predisposed cases cause a gangrene of these parts extending as far as the application.

This gangrene assumes the typical appearance of dry gangrene. It is caused by the formation of thrombi in the vessels, and if the application be kept up for a sufficient length of time will result in an entire occlusion of all the vessels in the field of contact, thus robbing the parts of all nutrition.

This thrombosis and subsequent occlusion is directly caused by the degenerative action of carbolic acid upon both the red and white blood corpuscles. There are no circulatory disturbances of note caused by the action of the acid upon the vasomotor nerves.

The longer the acid is allowed to remain in contact with the parts, the deeper the gangrene will spread.

This action is especially frequent in such parts as are entirely surrounded by the dressing—notably the phalanges of the extremities.

The use of carbolic acid in the form of moist dressings is especially prone to cause gangrene.

The danger of carbolic acid gangrene is especially predominant in weak subjects, women and children.

In conclusion, we would infer from the results of these observations and experiments that the use of carbolic acid as a dressing in minor or major surgical operations should be restricted as much as possible, and other equally efficacious antiseptics substituted; and, finally, that the profession should warn the laity against the indiscriminate use of the drug in the treatment of injuries.

Book Reviews.

TREATISE ON MEDICAL AND SURGICAL GYNÆCOLOGY. By S. Pozzi, M. D., Professeur Agrégé à la Faculté de Médicine Chirurgien de l'Hôpital Lourcine-Pascal, Paris. Complete in Two Volumes. Translated from French Edition under the supervision of, and with additions by, BROOKS H. WELLS, M. D., Lecturer on Gynæcology at the New York Polyclinic; Fellow of the New York Obstetrical Society, and the New York Academy of Medicine. Volume Two. With 174 wood-engravings, and 9 Full-page Plates in Color. Royal Octavo. 174 wood-cuts. Muslin, $6.00; sheep, $7.00; half morocco, $8.00.

The first volume of Pozzi's Gynæcology was favorably noticed in these columns some months ago. Volume second fulfils all the expectations raised by its predecessor. Undoubtly the work will take rank as the leading exposition of modern gynæcology. It is not to be expected that every theory and every statement of the author will find acceptance; but his book is so comprehensive, progressive, and so distinctively fresh and modern that it must gain universal favor. It is refreshing to find many untenable theories of the older authors (especially as to the pathology and therapeutics of pelvic imflammation and extra-uterine pregnancy) ignored, and instead to find modern theories based upon the facts proved by the experience of the past twenty years. Gynæcology has developed so marvelously during this time, and the mass of facts accumulated has been so great, that it is now possible to write a scientific treatise upon this subject. It is no longer possible to sustain theories either as to pathology or treatment upon reputation of their discoverers and promulgators. Hence we can chronicle the passing away of the but recently accepted theories concerning pelvic inflammation, cellulitis, pelvic abscess, hæmatocele, displacements of the womb, the perineal body, etc.

Chapters I–IV deal with the many and complex problems of pelvic inflammation in a manner which will find approval with all who have had opportunities for studying the subject not only clinically but also by abdominal section. Special statements will, of course, be challenged, but on the whole we know of no exposition of this subject equally good. The author regards sepsis in childbed and gonorrhœa as the great causes of pelvic inflammation. He considers also that almost without exception the extension of the inflammation takes place along the mucous lining of the uterus and tubes, and yet he distinctly upholds the doctrine that at times—especially if not exclusively during the puerperal state—extension takes place along the lymphatics. The doctrine is laid down in positive terms that salpingitis is precedent to and a part of almost every case of peritonitis; and this is emphasized by treating the subject under the title perimetro-salpingitis. The innovation is to be commended as fixing upon the mind of the student the fact that almost without exception salpingitis precedes, causes, and is a part of pelvic peritonitis. The strictly minor rôle of inflammation of the pelvic cellular tissue also is amply elaborated. It occurs at times as a result of puerperal infection. This is the usual form. It occurs also as a result of inflammation of the uterine appendages. Pozzi also admits (but gives no proof) that it occurs as a result of dirty operations upon the uterus. In view of all the facts proof should have been forthcoming for this statement to gain credence. Well-observed cases, with autopsies, as for instance those reported by Coe, of the Woman's Hospital in New York, of deaths from septic inflammation following operations on the uterus, show that in such cases the inflammation spreads to the peritoneum through the Fallopian tubes. The portion of these very excellent chapters most open to criticism is that relating to the treatment of pus in the pelvis. The author admits the propriety of *simple incision* of the pus collections under several conditions—at the same time admitting the danger and deficiencies of the method. Many excellent gynæcologists absolutely reject such measures, and treat all such cases by cœliotomy; others probably with greater wisdom reserve incision for cases of broad ligament abscess, or suppurating hæmatoma—both rare conditions—and certain cases of pelvic abscess when the patient is exhausted and suffering from general sepsis. In the last class of cases by evacuating the pus the patient can at times be improved so as to withstand the shock of a radical operation to remove the abscess sac.

Chapters V—IX treat of tumors of the uterine appendages, broad and round ligaments. The treatment of these subjects is satisfactory, but conventional. Chap- X is devoted to genital tuberculosis, and

Chapter XI to hæmatocele. Unfortunately this was written before the general acceptance of the fact that most cases of hæmatocele are cases of ruptured tubal pregnancy. The author advises the policy of doing nothing, which is clearly inadmissible because of the dangers of recurrent and fatal hæmorrhage. While it is true that cases of hæmatocele recover under the expectant treatment, it is none the less true that very many die from further hæmorrhage. Fortunately abdominal section in good hands will save almost every case.

Chapter XII covers the subject of ectopic gestation admirably. The author everywhere takes advanced ground. The work of the past is chronicled and due praise given to the many who have added to our knowledge of this subject. But great advances are predicted for the future. The currently accepted pathology in given, primary abdominal and ovarian pregnancy being admitted. But these are regarded as most rare, and due caution is exercised in accepting doubtful examples. Werth's view that an ectopic gestation should be regarded as a malignant tumor, to be removed promptly after its discovery, is commended. Prompt removal of the gestation sac is advised in all cases before the fifth month; injections of morphia, and electricity are condemned, as being uncertain if not unsafe. The dangers inherent in the condition are considered greater than those of the operation. It is gratifying to find such sound doctrines taking vigorous root in French soil. Prompt operative interference is advised also for the later months. The dangers of hæmorrhage and septicæmia being regarded as greater that those of an operation. It is pointed out that recent operations have been much more successful than older ones. Thus up to 1886 Harris reports thirty sections done during the viability of the child with five mothers and sixteen children saved; whereas since that date of thirteen cases, nine women and eleven children were saved. Much is expected from prompt operation with a perfected technique. The author states, "here, as in all the problems of abdominal therapeusis, the theoretical objections of a timid surgeon fall before the results of a bolder practice characterized by good technique." The results under expectant treatment until after false labor having been so deplorable, the courageous surgeon will be emboldened to apply his art for the relief of these women in such peril of their lives. With modern hæmostatic forceps and an abundance of gauze for packing, the skillful surgeon should be able in most cases to successfully remove the gestation sac and add another triumph to abdominal surgery. Cases in which the placenta grows from the intestines will probably remain a dangerous class to deal with.

Chapters XIII—XXIII deal with diseases of the vagina, vulva and perineum. Chapters XXIV—XXVI treat of malformations of the genital organs and Chapters XXVII—XXVIII of diseases of the urinary tract, rectum, and pelvis, thus giving the book a wider scope than is usual with treatises upon gynæcology.

Periscope.

THERAPEUTICS.

TINCTURE OF IODINE IN INFECTIOUS ULCERS OF THE CORNEA.

Chibret (*Rec. d'ophthal.,* September, 1891) thinks he has found in tinctures of iodine the following necessary properties: 1. A powerful and general antiseptic action. 2. Energetic dialytic power. 3. Absence of formation of insoluble salts causing indelible opacities of the cornea. 4. Non-destructive effect on the cornea. He thinks his belief in the value of this drug has been fully justified by ihe results, and he even recommends its use in corneal scars and opacities.

TREATMENT OF THREAD WORMS.

Heath (*British Medical Journal,* December 10, 1891, p. 1300) writes that within the last few years the views about ascarides have greatly altered. It used to be thought that they lodged entirely in the rectum, and that the patient could be cured by copious enemata, usually of salt and water. But it has been shown within the last few years that it is not a fact, and that these ascarides have their habitat mainly in the cæcum, and are to be found, more or less, throughout the whole length of the large intestine. It must, then, be borne in mind that it is not sufficient to attack the rectum with enemata, but purgative medi-

cine must also be given which shall act upon the cæcum and clear away the worms themselves and the mucous in which they are lodged. You may often see them coming away in large balls as the result of purgative medicine, and until they are thoroughly cleared out you cannot hope to cure the patient.

CANTHARIDINATES IN TUBERCULOSIS.

Demme (*Therap. Monatsh.*, March, 1892) has treated 30 cases by subcutaneous injection. The potassium salt was used at first, but the sodium preparation gave rise to less pain. There was never any suppuration at the site of the injection, but in one case a considerable swelling occurred without any reddening of the skin. It took long to subside. The dose used was 0.0001 to 0.0002 g. In 10 cases of more or less severe laryngeal with pulmonary tuberculosis no conclusion could be formed owing to the insufficient length of the treatment. After giving short details of the remaining 20 cases, the author makes the following remarks: Results are obtained by this treatment more surely than by any other method. The drug must be used with great caution, for albuminuria appeared in every case. This albuminuria lasted longer than the treatment in 5 cases. The effect on the lungs is slight, but expectoration becomes easier. In the larynx the œdema, especially that over the arytenoid cartilages, disappears almost completely. More solid infiltrations also tend to become smaller more quickly than under other treatment. While some cases were greatly improved and might (if the albuminuria could be avoided) be looked upon as cured so far as the larynx was concerned, two were certainly cured. In other cases temporary improvement alternated with relapse.—*Brit. Med Jour.*

LOCAL APPLICATION OF CALOMEL IN INFLAMED HÆMORRHOIDS.

Dr. B. James (*La Semaine Médicale*, No. 11, 1892) has employed with success for several years the local application of calomel in inflamed hæmorrhoids. The remedy is applied topically by the fingers to the swollen and inflamed parts. This rapidly causes all the morbid symptoms to disappear. The writer has not seen a single case resist the action of this remedy.

MEDICINE.

EMIGRATION OF LEUCOCYTES FROM THE TONSILS.

Dr. Polyak finds that most of the leucocytes which in a normal condition of the tonsil migrate through its epithelium into the buccal cavity are lymphatic corpuscles (lymphocytes)—that is to say, young elements generated by karyokinesis of the cells of the adenoid tissue. There are, however, in addition, a considerable number of leucocytes with polymorphic nuclei which migrate from the superficial capillaries and capillary veins. The emigration of these multi-nuclear leucocytes is also observed in places where there is fibrous connective tissue beneath the epithelium. The emigration of large numbers of lymphocytes is accompanied by well-marked destruction of epithelium close to the free surface, but the emigration of the multinuclear leucocytes only appears to give rise to increased exfoliation of the superficial epithelial cells. When acute inflammation of the mucous membrane was induced by irritation with chemicals, the emigration through the many layers of flattened epithelium was mainly confined to multinuclear leucocytes.—*Lancet.*

ON THE KNEE-JERK IN THE CONDITION OF SUPERVENOSITY.

Dr. T. Hughlings-Jackson makes a short preliminary communication on this subject in the *British Medical Journal*, 1892, No. 1624. He has observed absence of knee-jerks in some cases of emphysema with bronchitis, where the blood has become venous in an extreme degree. As the patients observed were near death, he hesitates to conclude that they were absent as a mere consequence of supervenosity. He quotes the case of a girl of nine years suffering from diphtheria, who was tracheotomized at midnight for urgent respiratory difficulty, producing cyanosis. Before the operation her knee-jerks were absent. On the following day, the cyanosis having then disappeared, the jerks were obtained and remained present until her discharge from the hospital. The knee-jerks of a dog artificially asphyxiated by clamping the trachea were absent in the

third stage of asphyxia, having been exaggerated in the earlier stages of the condition. It is suggested that the preliminary exaggeration was owing to the loss of cerebral control over the lumbar centres, the eventual loss being occasioned by the succumbing of these strongly organized spinal centres to the poisonous influence of supervenous blood.

The testing of knee-jerks before and after the administration of oxygen to cyanosed patients may be expected to throw light on the question. If supervenosity is a cause of loss of knee-jerks, that fact may be important in the apoplectic state, and possibly somewhat with regard also to post-epileptic coma. Careful observations on such cases may be productive of valuable results.

ANKYLOSTOMIASIS THE BERIBERI OF ASSAM.

According to the *Indian Medical Gazette* for February, 1892, Dr. G. M. Giles finds that the disease known as the beriberi and the kala-azar of Assan are identical, and that they are in reality ankylostomiasis caused by the *Dochmius duodenalis*. This parasite, Dr. Giles finds, develops slowly if at all in drinking-water, but develops plentifully in fæces. The ingress of the parasite into the human system is believed to be due to the habit of cleansing kitchen and table utensils with infected earth, and of eating food from a mat on the ground. The symptoms and causation of the disease are the same as those found by Dr. Kynsey in the so-called beriberi of Ceylon.

THE CEREBRAL CIRCULATION DURING HYPNOSIS.

Drs. Sarlo and Bernardina (*Rev. Sperimentale* XVIII, III), publish an article on this subject in which they discuss some of the physiological literature and elaborately report a case in which they were able to make a careful study of the cerebral pulse through an aperture in the skull due to an old traumatism, and their paper is illustrated by sphygmographic tracings. The authors conclude as follows: (1) The cerebral circulation is different according to the hypnotic conditions, it appears that there may be hyperæmia in the reduced lethargic state and anæmia in the thus induced cataleptic condition. (2) Everything leads us to believe that antagonism between the cerebral and the peripheral circulation, during tne hypnotic state does not exist. (3) A greater frequency and an apparent increase of the respiratory oscillations are observable in the hypnotic condition. (4) The psychic functions, during the hypnotic conditions, incite a vascular reaction, identical with that which occurs in the normal state, but less marked on account of the existing vascular constrictions. (5) The hypnotic state should not be considered as anything by itself, but serves only to put in evidence what already exists. The hypnotic manipulation, of whatever kind (sensory stimulation, suggestion, etc.) has only the effect to increase the excitability of such nerve centers that are, as it were, the *locus minoris resistentive*, and detach or functionally cut off certain nerve elements from the complex that forms the organic substratum of the healthy mind. In our case the cortical motor elements, morbidly excitable, were, through the hypnosis, separated from the rest.

SURGERY.

PARTIAL NEPHRECTOMY AND REUNION OF RENAL PARENCHYMA.

Tuffier (*Archiv. Gènèr. de Mèd.*, July, 1891). Renal cysts are frequently mistaken for ovarian cystoma. Of these, the unilocular are benign in opposition to the multilocular ones. In the former the renal parenchyma is sufficiently extensive as to leave no doubt as to the desirability of preserving the organ as functionally useful. Complete nephrectomy, it has been heretofore held, offers a better chance of recovery in these cases of renal cysts than incision. The discouraging results in this operation, however, led the author to institute a series of experimental studies (Gaz. Hebd., 1888, 1890, *Archiv. Génèr de Mèd.*, 1891), which developed the fact that hæmorrhage from the renal parenchyma may be controlled by compression of the vessels of the hilum and suture of the renal tissue. Such renal wounds heal readily and fistulæ are only observed to occur in cases in which the ureter has been injured. He therefore proposes to carefully dissect only the renal cyst, and to

suture carefully the walls of the cavity in the substance of the kidney. This procedure was carried out successfully in a case communicated by T. After enucleation of the cyst the renal tissue was sutured by deep catgut sutures, the capsule being sutured separately, hæmorrhage ceasing as soon as this was accomplished; no drainage was employed. The wound healed kindly. In this case an epithelioma of the bladder was subsequently removed by suprapubic cystotomy. The subsequent fate of the patient is not recorded.

EUROPHEN IN SURGICAL DRESSINGS.

The respective advantages of dry and moist dressings have received much attention of late. A point was made concerning dry dressings which did much to decide operations in their favor. We refer to the quality possessed by some of them of adhering closely to exposed surfaces thus making an impervious, antiseptic covering, beneath which the reparative processes may uninterruptedly take place. This adhering property is observed in a marked degree in europhen, which has attained a high reputation as a cicatrisant. Europhen, too, is a bulky powder which may be spread to advantage over large denuded surfaces in cases in which it would be dangerous to employ iodoform. The antiseptic and stimulating properties to europhen have, no doubt contributed greatly to its success, for its cresolic component promptly shows a characterisfic action. The iodine contained in europhen goes off slowly, thus preventing the toxic action so often recognized in preparations of iodoform, and making frequent dressing necessary, while its solubility in the liquified products of inflammation add to its effectiveness as well as its safety. In the lesions of syphilis, in ulcerated surfaces, burns and all traumatisms, this new dressing has done admirable work. Europhen has undoubted advantage over iodoform in being free from disagreeable odor or toxic influences.

IMPROVEMENTS IN THE ELECTRO-ENDOSCOPE.

Dr. Oberländer (*Archiv für Derm. und Syph.*, 1892, III. Heft.) gives an account of some improvements which have been devised as a result of suggestions furnished by a more or less constant use of the endoscopes of Nitze and Leiter.

The most important improvement seems to be a substantial enlargement in the caliber of the tubes used. Formely only instruments with a caliber of 22 to 24 F. was employed. It was found, however, that in a large proportion of the cases examined tubes of 28 to 30, and even 32 F., could be introduced. As these yielded a much larger field of vision and better illumination, their use was found to be of great clinical value.

The advantages to be derived from practicing internal urethrotomy, under guidance of the eye, by means of improved endoscopic instruments, are spoken of and the apparatus described and illustrated. (This procedure was, however, first described and practiced by Dr. F. Tilden Brown, of this city, who demonstrated its practicability and exhibited his instruments before the Genito-Urinary Section of the N. Y. Academy of Medicine, some six months before the publication of this paper.)

The writer is of the opinion much may be expected from the employment of electrolysis and the direct application of the galvano-cautery, in stricture and hypertrophic disease of the urethra: and his appliances for carrying out these suggestions are also described among the more recent improvements. Considerable advantage has been gained in deep urethral endoscopy by the employment of the hinged-obturator which enables the observer to introduce the straight tube to the membraneous urethra without pain or difficulty.

OBSTETRICS.

COMPLETE RUPTURE OF UTERUS.

Winter (*Centralbl. f. Gynäk.*, No. 1, 1892) exhibited a uterus before the Berlin Obstetrical Society not long ago. A rent passed obliquely through the anterior walls, and reached from the contracting ring nearly to the os externum. The serous coat was divided as far as the level of its firm attachment to the muscular tissues, so that there was communication with the peritoneal cavity through a rent nearly 4 inches long. At the necropsy, the uterus was found strongly anteflexed,

and the intestines and parieties had already (within 28 hours) adhered around the rent so as to cut it off from the peritoneal cavity. The patient was a 3-para, aged 29 ; one labor was normal, one required forceps. The third was at term, and began naturally. In ten hours the water broke and the pains ceased. About nine hours later, rupture of the uterus occurred, the head slowly receded from the pelvis, and a trifling amount of flooding took place. The patient was sent into a lying-in hospital. Winter found that the child had entirely escaped into the abdominal cavity, and lay in the first position, close under the parietes. The temperature was normal, the pulse 124; there was evidence of peritonitis, but not of severe hæmorrhage. The indication was, he thought, to deliver at once, rather than to take steps to check hæmorrhage. He did not deem it advisable to attempt to deliver through the rent and out of the vagina, as the fœtus lay far from the uterus, and the rent, if enlarged, would be the source of fresh hæmorrhage. He made a short incision through the abdominal walls, and drew out the fœtus and placenta within ten minutes. There was but little collapse; the symptoms of peritonitis subsided for awhile after the operation, but soon reappeared, and the patient died in twenty-eight hours. Nevertheless, Winter holds that the simple operation which he performed was preferable, in cases where little hæmorrhage or fear of hæmorrhage existed, to the long, difficult, and complicated suturing of the uterus in abdominal section. The following table gives the results of thirty-seven cases of rupture of the uterus, with complete escape of the child into the peritoneal cavity:

Treatment.	Number.	Deaths.
Died undelivered	5	5
Delivered through the rupture	8	5
Abdominal section after delivery through the rupture	1	1
Abdominal section, and delivery through incision; no suturing of uterus	12	4
Abdominal section and delivery through incision; suture of uterus.	7	5
Porro's operation	4	4
Total	37	24

Thus delivery through a simple incision in the abdominal walls gives a percentage of 66 for recoveries.—*British Medical Journal.*

GYNECOLOGY.

DIABETES AND THE FUNCTIONS OF THE FEMALE ORGANS.

Strojinowski (*Nouv. Arch. d' Obstet. et de Gynêc.*, March, 1892, Supplement.) on the basis of eleven cases under his own observation, states that diabetes not only causes suppression of the catamenia, but also distinct atrophy of the uterus and ovaries.

CIMICIFUGA IN THE TREATMENT OF DYSMENORRHŒA AND OVARIAN IRRITATION.

Following the example of Boddie, of Edinburgh, Dr. James Brunton has employed blacksnake-root in the treatment of dysmenorrhœa and ovarian irritation. He employed 30-minim doses of the tincture thrice a day, and was able to dissipate the occipital headache and ovarian pains from which his patient suffered. In cases of dysmenorrhœa, similar doses every four hours produced great benefit.

Brunton believes that the drug is an anodyne, which is valuable as a substitute for the bromide sand opiates in dysmenorrhagic pain.

When given for dysmenorrhœa, it should be given four days before, and continued over the period.

In metrorrhagia, and menorrhagia, he believes it is a regulating agent, although it is sometimes disappointing in its action. —*Practitioner*, April, 1892.

HYSTEROPEXY.

Chaput (*Annales de Gynëc. etd' Obstët.*, April, 1892) discusses the treatment of uterine retroflexions. In simple retroflexion where the uterus is freely movable, the pessary is sufficient, though the curette may be needed; but in more advanced reflexions where the pessary cannot be used, abdominal section is needed. This proceeding is preferable to vaginal hysteropexy, as it allows the operator to choose between simple replacement of the uterus, removal of the appendages with or without fixation of the uterus (abdominal hysteropexy), and fixation without castration. As fixation of the uterus itself is not in all respects advisable, Chaput recommends that the pedicles of the amputated appendages be fixed to the abdominal wound, or that the round ligaments be shortened, if re-

moval of the appendages be inadvisable. In the discussion on this communication, P. Petit advocated Alexander's operation. He said that it had fallen into discredit owing to the many indications for thorough treatment of complications in each case. It sometimes proved necessary, he declared, to perform, at the same sitting, curettage, plastic amputation of the cervix, anterior colporrhaphy, colpoperineorrhaphy, and shortening of the round ligaments. Chaput objected that it was impossible to diagnose all the complications which interfered with the success and value of Alexander's operation without an abdominal exploration, which at once altered all the conditions associated with that operation. Petit did not think highly of hysteropexy. In one case, performed by a good operator, the pains from which the patient had suffered continued, and a bad ventral hernia developed. In another the patient was sick on recovering from chloroform, and the vomiting caused the threads to cut their way through the uterine tissue into which they had been passed. The patient died of hæmorrhage.—*Brit. Med Jour.*

ENDOTHELIOMA OF THE OVARY.

Rosthorn (*Archiv für Gynäkologie*, Band xli., Heft 3) describes and figures the appearances observed in microscopical sections of so-called endothelioma, which he regards as a true neoplasm, favoring the term "sarcoma perivasculaire" applied to it by Ackermann. He thinks that capillary stasis is doubtless an ætiological factor in its development. Several forms of endothelioma may be distinguished according to their mode of origin and the prevailing histological structure.

PEDIATRICS.

ACUTE CHOREA, WITH FATAL ENDOCARDITIS.

Stahl, (*Annals of Gynæc. and Pædiatry*, Phila., 1891, v., 183.) gives the following case:

C. M., female, aged six. Family history free from any neurotic tendency, or other discoverable predisposition to disease. For a week or ten days before seeking medical advice, she had complained of her legs and feet being asleep, the "numb feelings" seemed to be confined to the lower extremities and not referred to the articulations.

On May 19, 1891, she was pale, had moderate fever (101°), pulse 130, small and somewhat irregular in rhythm, tongue coated, stomach irritable, frequent vomiting, bowels constipated, some cough. There were small moist râles over both lungs with no impairment of resonance. There was presystolic and systolic mitral murmur, without increase in cardiac area. There was considerable dyspnœa. Three days later there developed a mild chorea, most marked on the right side. It reached its greatest severity and rapidly subsided. The dyspnœa, meanwhile, increased and the pain about the heart became more severe. By the twelfth day the choreic movements were no longer present, the dyspnœa now amounted to orthopnœa, the murmur had not changed in character, there was puffiness about the extremities, and the lungs were more congested. The child died the twentieth day from my first visit of heart failure due to dilatation. No autopsy allowed.

INFANTILE MELANOSIS.

A rare case of melanosis of the lower jaw in an infant is recorded in the current number of the *Annals of Surgery* by Charles A. Power, of New York. The child was three months old when it came under observation. The swelling was about the middle of the left side of the gum of the lower jaw, and in size about that of a small almond, oval, of moderately firm consistency and covered by mucous membrane which was apparently normal. An exploratory incision was made which yielded no pus. At the end of a month; when the child was again brought to the hospital, the swelling had much increased in size. It projected well beyond the middle line of the mouth, pushing the tongue far to the opposite side. It was dense, and firmly attached to the body of the jaw, which, when felt externally, was much enlarged and resistant. Ultimately the left half of the jaw was removed under chloroform. The ordinary incision along the lower border of the bone was used, the body divided a little to the right of the symphysis, and the condyle dissected from the glenoid cavity. The operation occupied a little over an hour. The patient took the anæsthetic badly, failed to rally,

and died two hours after being returned to the ward. On microscopic examination the tumor proved to be a true melanotic growth, springing from the periosteum of the lower jaw. The author adds that the patient would have had a better chance of life had time been taken up in operating. But in so young a subject such a procedure as was carried out would in any case have proved one of a very formidable nature.

SULPHUR IN THE TREATMENT OF CHLOROSIS.

Prof. Hugo Schulz (*Med. Neuigkeiten*, No. 17, 1892) recommends sulphur in cases of pure chlorosis where iron has no action. In such cases the general condition is much improved by the administration of sulphur. After this drug has been given for a time the use of iron may be begun and successfully carried out. On the contrary, it is not well borne in catarrhal and inflammatory states of gastro-intestinal tract. The form of administration is:

℞ Flowers of sulphur.....5 ijss.
Milk, sugar.....5 xxv.
Sufficient for ten powders. A knife-pointful three times a day.

HYGIENE.

STOP SPITTING.

Says Dr. T. M. Prudden:—"If the vile and increasing practice of well-nigh indiscriminate spitting goes unchecked in nearly all assembling places and public conveyances; if the misguided women who trail their skirts through the unspeakable and infectious filth of the street are to be admitted uncleanzed into houses and churches aud theatres; if theatres and court-rooms and school-houses and cars are to remain the filthy lurking-places of contagia which their ill ventilation and their mostly ignorant and careless so-called cleaning necessarily entail; if in sleeping-cars and hotel bedrooms the well are to follow consumptives in their occupancy without warning, or even the poor show of official disinfection; if in ill-ventilated and ill-cared for dwellings the well must breathe again and again the dust borne seeds of tuberculosis; if no persistent warning is to be given to the ignorant of the dangers which lurk in uncleanliness—then our task will be most complex as well as difficult in limiting the contagiousness of tuberculosis."

Of course cleanliness and plenty of water are necessary, but, after all, it is the expectoration which carries the germ and promotes the spread of disease. Spitting, it seems, is not only a vile, but an increasing habit. This is an unfortunate social fact which reformers do not seem to have grasped, despite its noxiousness. Shall we not have to have Society for the Prevention of Expectoration—except into sanitary spit-cups? If one could stop the spitting habit, prevent the spread of consumption, and finally stamp it out, he would be greater than a tariff reformer.—*Medical Record.*

EFFECTS OF ANTISEPTICS ON VIRILITY.

Attention is called by Dr. Van Den Corput (*Rev. Therap.*) to the diminution of virile power which he has observed in patients to whom he had prescribed antiseptics, such as salicylic acid, quinine, menthol, carbolic acid. The author supposes that these antiseptics act on the blood elements, and on the seminal cells as on inferior organisms. The spermatozoids become in effect completely immobile under the microscope, like all the leucocytes, which lose their amœboid movements, and can no longer effect their migrations. Salicylic acid acts in the same manner upon the ovary, and causes the lengthening of the menstrual period.

AVINE TUBERCLE VERSUS HUMAN TUBERCLE.

Some further experiments are recorded by Mr. Charles Richet on the protection afforded against tuberculosis by inoculation with cultivations of the bird tubercle. This micro-organism, though closely allied to the normal microbe, differs from it in several important respects. Thirty dogs, all in robust health, were taken, nine of which were thus inoculated without giving rise to any local or constitutional manifestations. All the animals were then inoculated with a cubic centimetre of cultivation of the active human tubercle bacillus. Within a month from the date of inoculation every non-vaccinated animal had succumbed to the disease, while the nine dogs previously treated to a dose of the bird tubercle remained in good health. So far as they go those observations possess very great interest, but it is

hardly necessary to point out that it would be premature to conclude that we are yet in possession of the means of protecting human beings againt this terrible malady. It is a far cry from the laboratory to the sick-bed, and it is notoriously unsafe to apply the results obtained in the treatment of maladies experimentally induced to maladies occurring as part of a constitutional condition.—*Med. Press.*

MEDICAL CHEMISTRY.

A NEW REAGENT FOR ALBUMIN.

A. Jaworowski proposes a new reagent for albumin which detects the presence of $\frac{1}{3000000}$ part of albumin. (The other known reagents, as, for instance, Bodecker's, Millon's, acetic acid, and others do not detect even the $\frac{1}{600000}$ part.) The reagent is prepared after the following formula: One part of molybdenate of ammonium is heated with 40 parts of water, and afterwards mixed with 5 parts of tartaric acid, when, if the liquid is not clear, it must be filtered. For examination, the urine must be transparent and acid; if it is necessary to acidify it, tartaric acid is used. For the complete removal of albumin from the urine, add a few drops of the reagent and filter it; after filtration, add the reagent again, and so on till a precipitate ceases to be thrown down. Too much reagent must not be used at once, because the excess may redissolve the albumin. By this reagent, also, a very small quantity of mucus may be detected.—*Wiadomosci Farmaceutyczne*, November 1, 1891.

A RESEARCH ON THE POISONOUS NATURE OF MOULDY RICE.

Dr. J. Sakaki, in tho *Sei i-kwai Medical Journal*, reports the results of his study upon the action of mouldy rice. The research is particularly interesting because it has been thought by students of the disease known as *kakke* that mouldy rice was the cause. From the experiments which Sakaki has made upon frogs and rabbits, it would appear that the poison is capable of producing, in the case of the rabbit, dyspnœa, rapid pulse, pupillary dilatation, and paralysis, the animal dying in convulsions in from three hours to forty-five minutes. In the frog it caused paralysis of the forelegs and loss of reflex activity. Finally the batrachian was unable to recover its former position when placed on its back. Respiration became feeble and only very severe stimulus elicited any response.

THE FLUORESCENCE OF QUININE CONCEALED BY PHENACETIN.

From medico-legal investigations conducted by F. Sestini and R. Campani (*L' Orosi and Chem. News*), they have arrived at the following conclusions: The presence phenacetin conceals the fluorescence of sulphuric acid solutions of the cinchona alkaloids, especially when dilute. Aqueous solutions of phenacetin are colored yellow on the addition of chlorine water and ammonia, but mixtures of quinine and phenacetin are colored light-blue (methylene blue).

NEWS AND MISCELLANY.

PARADOXICAL.

The *Scientific American* says that there is much truth in the remark of one who observed, "The worst thing about the grip is that you are sick with it so long after you get well."

THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Will hold its Eighteenth Annual Session at Cincinnati, Wednesday, Thursday, and Friday, Oct. 12th. 13th and 14th, 1892. An excellent program, containing the best names in the valley and covering the entire field of medicine, will be presented. An address on Surgery will be delivered by Dr. Hunter McGuire, of Richmond, Va., President of the American Medical Association. An address on Medicine will be made by Dr. Hobart Amory Hare, Professor of Therapeutics and Clinical Medicine, Jefferson Medical College, Philadelphia. The social as well as the scientific part of the meeting will be of the highest order.

The Mississippi Valley Medical Association possesses one great advantage over similar bodies, in that its organic law is such that nothing can be discussed during the sessions save and except science. All ethical matters are referred, together with all extraordinary business, to appropriate committees—their decisions are final and

are accepted without discussion. The constitution and by-laws are comprehensive and at the same time simple. Precious time is not allowed the demagogue or the medical legislator. The officers of the Pan-American Medical Congress will hold a conference at the same time and place.

GALEN'S HYMN TO THE CREATOR.

In my opinion, true religion consists not so much in costly sacrifices and fragrant perfumes offered upon his altars, as in a thorough conviction impressed upon our own minds, and an endeavor to produce a similar impression upon the minds of others, of his unerring wisdom, his resistless power, and his all diffusive goodness. For his having arranged everything in that order and disposition which are best calculated to distribute his favors to all his works is a manifest proof of his goodness which calls loudly for our hymns and praises. His having found the means necessary for the establishment and preservation of this beautiful order and disposition is as incontestable a proof of his wisdom as his having done whatever he pleased is of his omnipotence.—*Pettigrew's Medical Biographies.*

DEATH OF PROF. MEYNERT.

The Vienna school has lost another of its most ardent workers this week in the death of Prof. Meynert. Rumor has been for several months past active in publishing different vague accounts of the professor's state of health, but few had any notion of the end being so near. Psychiatry had been his life study, and his memory will long be preserved in that department in connection with his labors in the anatomy and physiology of the brain. Every ramification of the University has passed a tribute in his memory.

Hofrath Nothnagle, before closing his Klinikischen Vorlesung, said that science as well as their own *alma mater* had suffered a severe loss in Meynart. The mention of the name instantly brought the whole class on their feet. It is surprising to a foreign eye the devout adoration and demonstrative formality a calamity like this excites! While all stood Nothnagel continued his eulogistic elegy on the immortal works of Prof. Meynert, who had built up a branch of knowledge unknown to mankind before his labors began. Psychiatry before his time was a name without a meaniug—a chaos with no hope of order being restored. About the end of last century and the beginning of the present the clinical symptomatology was scanty and ill-defined. It is true we owe the fundamental origin of psychiatry to Griesinger, but Meynert was the spirit that gave the department a new impetus, He said to the students, "your text-books on the anatomy and physiology of the brain to-day are very different to those when Meynert commenced his labors. His was a poetic conception, not a mere descriptive brain anatomist; he was a profound thinker that obtained results not in the usual manner step after step, but rather as Müller's description of the poets,

> 'Where confusion is greatest,
> Order seems nearest.'"

Meynert was a great admirer of Shakespeare, and poetry in general, which he cultivated in his leisure hours.

Mental diseases he divided into three large groups—1st, the old symptomatico-clinic group; 2nd, the anatomical; 3rd, the physiological-experimental.

Prof. Kahlar opened his lecture with the subject which he termed a "catastrophe," that one of the brightest luminaries of the University had set for ever. His efforts were towards elucidating the nerve centre in two directions—1st, In tracing the nerve fibres to their origin, and may be termed his anatomic labor. 2nd. His method of sectional series, or localization of the brain. To Meynart alone is due the credit of laying the foundation of this important section of modern knowledge.

Prof. Zuckerkandl said Meynert had opened a new epoch in the history of medicine, as to him is due the precise expression of symptoms for localization. His writings are numerous and varied, but his anatomy of the brain is sufficient to immortalize his name.

Profs. Krafft-Ebing, Toldt, Exner, etc., gave similiar testimony of Meynert's worth. Exner said that Meynert had been accustomed for some time past to liken the brain to a large globular projection draped with a mantle of grey matter which reflected the outer world as a brilliant mirror, this mantle was populated with images and sensitive beings.—*Med Press.*

WM. R. WARNER & CO.

SEDATIVE. ANODYNE.

EFFERVESCENT
BROMO
(WARNER & CO.)
SODA.

Caffein 1 Grain, Bromide Soda 30 Grains in each heaping teaspoonful.

USEFUL IN

Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Sea-sickness, and Epilepsy.

Dose and Composition.—A heaping teaspoonful, containing Bromide Soda 30 grains, and Caffein 1 grain, in half a glass of water, to be repeated once after an interval of 30 minutes, if necessary.

ANTI-RHEUMATIC. SEDATIVE.

EFFERVESCENT.
BROMO
(WARNER & CO.)
LITHIA.

EACH DESSERTSPOONFUL CONTAINS:
℞ Salicylate Lith a 10 grains, and Bromide Soda 10 grains.

A REMEDY IN THE TREATMENT OF
RHEUMATISM, GOUTY DIATHESIS, ETC.

Dr. A. Garrod, the well-known English authority on Gout, who was the first physician to introduce the Lithia Salts in the treatment of Gouty Diathesis, states that their action is materially increased by being administered in a *freely diluted form.*

This effervescing salt of Lithia furnishes an easy and elegant way of applying Dr. Garrod's methods.

INGLUVIN

A SPECIFIC FOR VOMITING IN PREGNANCY.
A POWDER:—PRESCRIBED IN THE SAME MANNER, DOSES & COMBINATION AS PEPSIN
In Doses of from 10 to 20 Grains,
AND A POTENT AND RELIABLE REMEDY FOR THE CURE OF
Marasmus, Cholera Infantum, Indigestion, Dyspepsia and Sick Stomach,
caused from debility of that organ. It is superior to the Pepsin preparations, since it acts with more certainty, and effects cures where they fail.

The Model Ledger enables a physician to make out his bills with great ease. Beside this, it tells at a glance just how much he has earned in any quarter; how much he has received; and how much is still due him. These are all good things for a doctor to know.

SURGERY OF THE GALL-PASSAGES AND LIVER.*

By. DR. W. KÖRTE,
BERLIN, GERMANY.

The surgical treatment of diseases of the gall-passages and liver has been given a great impetus during the last decade, and has developed into a most successful and promising branch of operative surgery. The therapeutics advocated in the various affections of these parts are by no means uniform, but even to-day are subjects of discussion and controversy. It would appear to me, therefore, that an unbiased description of the results obtained in the treatment of a series of diseases of the liver and gall-passages would be of value to the profession.

These cases are divided into the following groups:—

1. Diseases of the gall-passages.
2. Abscess of the liver.
3. Subphrenic abscess.
4. Echinococci of the liver.
5. Injuries of the liver.

1. DISEASES OF THE GALL-PASSAGES.

The most frequent cause for surgical intervention in the above is the presence of stone in the gall-bladder or ducts, and one which has been productive of excellent results in these diseases.

Gall-stones are caused by a precipitation of bilirubin, bilirubinate of lime and cholesterin upon the detritus and epithelial masses, in places where the gall becomes stagnant. This, of course, occurs most frequently in the gall-bladder. According to Naunyn, the starting point of such a concremental formation lies in a "desquamative angiocholitis." He is inclined to believe that a desquamative inflammation of micro-organisms is causative of this result. Any factor which tends to augment a stagnation of the gall, augments as well the formation of gall-stone. Among these may be principally mentioned the conventional dress of women of the present day, compressing as it does the region of the liver; or again, the compression exerted by the abdominal organs during pregnancy. These facts amply explain the more frequent occurrence of gall-stone in women than in men. A change of the chemical composition of the gall, productive of the formation of precipitates, is as yet an unproven theory for the cause of gall-stone.

Gall-stones may exist without exciting any symptoms, either untoward or otherwise, and will be only discovered at an autopsy by chance. In about one-tenth of all the bodies of adults upon which post-mortem examinations are made the concretions are found. They have been found to be five times more frequent in women than in men. Nevertheless while their presence may frequently be productive of no harm to the patient, they may occasion both severe and dangerous symptoms. In the more favorable cases they may be pressed through the gall-duct and evacuated by the bowels. But even this passage of the stone through the gall-duct occasions most agonizing pain. Those frequent gall-stone colics which are unrelieved by any internal medication Langen-

* In translating this admirable lecture by Dr. Körte, we have made no effort to abridge it, fearing thereby to mar the completeness of an article which must doubtless be looked upon as being the most exhaustive monograph on the subject in any language.

The lecture was delivered before the Free Meeting of Surgeons, in Berlin, and it appears in the German in Volkmann's Collection of Clinical Lectures. Owing to its length we are obliged to publish it in several parts.

buch considers as justifiable indications for surgical intervention. So soon as a gall-stone has attained a certain size, it can be no longer passed through the gall-duct, and then serious difficulties and dangers to the patient are likely to develop. If the opening of the ductus cysticus becomes occluded, then "retention-cysts" of the gall-bladder are developed—*hydrops cystid. felleæ*—which by means of an increasing tension and fruitless contractions of the gall-bladder are in a position to excite serious difficulties. The results are considerably worse when the stone becomes fastened in the ductus choledochus. In this event the gall is shut off from the bowels, the digestion suffers, and the stagnation of the gall in the liver causes an absorption of the biliary substances into the blood, occasioning the condition known as deletery cholæmia. By means of the pressure of the incarcerated concrements, the walls of the gall-bladder or ducts become weakened, and perforation can follow. The most fortunate termination of this process is where the stone breaks its way into the bowel, although even this is accompanied by most severe symptoms. If a perforation into the abdominal cavity occurs, the outcome is likely to be still more serious. By means of a migration of microörganisms a suppuration of the gall-bladder can occur—an empyæma—complicated with all the dangers consecutive to an intra-abdominal suppuration.

It is not the gall-stone diseases in themselves that call for surgical intervention, but rather the various conditions which the diseases give rise to, especially when internal medication has been proven fruitless or the nature of the complication (mechanical obstruction) renders its inutility obvious.

In the treatment of this disease there is no concurrence between internal medicine and surgical interference, but the latter steps in as a remedial agent only when the former has failed. Here, as in all diseases in the cure of which both great branches of the healing science may be of value, a special education of the physician is of great necessity. The surgeon who intends to operate in diseases of the gall-bladder must intimately understand the normal course of these diseases, and the physician, on the other hand, must thoroughly understand where and when his duties should be supplemented by those of the surgeon. With such mutual assistance the welfare of the patient—our *suprema lex*—is best advanced.

The indications for operative interference may be tabulated as follows:

1. Frequently recurring gall-stone colics which are unrelieved by internal medication. This indication is a relative one, and must be modified by individual circumstances.

2. The development of lasting enlargements of the gall-bladder, after such attacks of colic, is accompanied by retention of the bile. Here the existence of large concremental formations may be taken for granted, which may of course give rise to any of the dangerous complications spoken of previously. Since the supervention of these most grave complications can occur at any time and render our surgical interference too late to do any good, I therefore consider such enlargements of the gall-bladder, accompanied by retention of gall, as an indication for operation, especially among the working classes, among whom physical labor is necessary. In case, however, of the existence of retention and enlargement of the gall-bladder, unaccompanied by any colic or other symptoms, operation should be delayed. Indeed, the patients in question would, under such circumstances, scarcely be expected to submit to an operation.

3. If after severe attacks of colic the gall-bladder continues to remain tender and enlarged, the existence of an inflammatory process in and around the gall-bladder may be accepted, which in its turn points to the existence of concremental formations with a weakening of the parts. In such cases, after the futile use of internal medication, there should be an operation.

4. When the existence of fever, pain and swelling point to the existence of a suppurative process, operation should, of course, on no account be delayed.

5. Symptoms of closure of the gall-duct, should, after the failure of any internal therapy, be regarded as an indication for operation.

In the confirmation of diagnosis, and the above indications, stress should be laid upon the fact that gall-stone colics are frequently not recognized as such, but are

called by all sorts of names, but especially "cramps." This fact is called attention to by Fürbringer.*

Regarding the distinction between tumors of the gall-bladder, gall-stone diseases, and all other affections of neighboring parts, I would say that frequently hemispherically protruding and quickly growing tumors of a malign nature can be mistaken for distended gall-bladders. As an example of this I will cite a case later on (Case VII). Continued observation of the case, or exploratory incision—which I consider fully justifiable in such cases—will remove all doubt. A complication of cholelithiasis with carcinoma of the gall-bladder or liver can also occur (see Case X), Marchand having perhaps been the first to call attention to this fact. An enlarged and especially movable kidney can be mistaken for an enlarged gall-bladder. Two of my female patients came to me with the diagnosis of "floating kidney." In such cases the kidney should be held back with the fingers of the left hand, while the right hand palpates the region of the gall-bladder. This will usually suffice to clear away any doubt on such a score. The slight movement of the gall-bladder during respiration cannot be regarded as any definite mark, since frequently the kidneys also move sychronously with the respiration. Further, in such cases where the gall-bladder is considerably enlarged and adherent through inflammatory processes, this respiratory movement may be entirely absent, or else only minimal. In general, the enlarged gall-bladder will be found closer to the anterior wall of the abdomen than a renal tumor or floating kidney. Again, the latter will be more distinctly felt anteriorly if pressed forward from the back. When the colon is inflated with air it lies in front of a renal tumor. Such is, however, not the case with tumors of the gall-bladder—indeed, it would be impossible. Renal colics can, as Fürbringer† has noted, be frequently confounded with gall-stone colics, especially if only the patient's evidence is taken into consideration.

The expulsion of the gall-stones through the bowels can only be confirmed by the most careful watching of the stools. When in spite of the passage of these gall-stones, the gall-bladder still remains enlarged and painful, it may be taken for an indication that larger concrements still remain, which are of such a size as not to be able to pass through the gall-ducts.

Further, a growth in the region of the pylorus may be mistaken for an enlarged gall-bladder. Careful palpation, however, will generally reveal the fact that in cases of pyloric tumor, one is able to insert the fingers between the edge of the liver and the tumor; again, the distention of the stomach with either air or water will aid in the confirmation of the differential diagnosis. When distended the fundus of the stomach is pushed forward and the pyloric growth will change its position, or in certain cases disappear almost entirely. By these means any mistake of diagnosis in this direction may be entirely avoided.

Cysts of the liver may also be mistaken for the enlarged gall-bladder; this happened to me in a case of closure of the gall duct. The history of this patient will be given further on (Case XII). There was a round prominence somewhat larger than a walnut on the edge of the liver, and in the region of the gall-bladder. Laparotomy revealed the fact that it was a cyst of the liver. The shrunken little gall-bladder lay under he edge of the liver and could not be felt at all. In a few cases I have also found some of the liver tissue lying over an enlarged gall-bladder. This occurrence was first called attention to by Riedel.*

Right here I wish to warn most emphatically against the performance of any exploratory punctures in cases of enlargement of the gall-bladder. This can only be without danger when confirming adhesions to the abdomen. After opening the abdominal cavity, I in all cases punctured the gall-bladder, and found that even the punctures of the smallest hypodermic needle were sufficient to cause an efflux of the bile. The great danger of such punctures prior to the opening of the abdominal cavity will, therefore, at once be seen. Although pure and undecomposed gall may not have any deleterious effect upon the peritoneum, it must be remembered, as Naunyn has proved, that micro-organisms may exist in the gall-bladder, especially in empyæma of this organ. The bacteria found by

**Verhandlungen d. Kongress f. Innere Medicine,* 1891.

†*Loc. cit*

**Berlin Klin. Wochenschrift,* 1888, No. 29.

Naunyn and also by me in the gall-bladder (see Case X), and named *coli commune* excite most severe general peritonitis. This has been demonstrated by Dr. Alex. Fränkel, in the *Wiener Klin. Wochenschrift*, 1891, No. 13.

Since Bobbs, Marion Sims, and Kocher first performed the operation of opening the gall-bladder for stone, the operation has rapidly grown in favor and variously modified in its technique. It is termed cholecystotomy and may be completed at either one or two sittings. In contradiction to this procedure, Langenbuch in 1882 recommended cholecystectomy, or excision of the gall-bladder in order to prevent possible recurrence by the removal of the seat of its growth. Courvoisier, Merideth, Spencer Wells, Bernays, and Küster produced and performed the operation of so-called "ideal cholecystotomy," which consisted in an incision of the gall-bladder, with subsequent suture of the part. These constitute the three principal methods for the surgical treatment of cholelithiasis; which, however, may be subdivided according to the variations of the details of their technique. For the operative treatment of closure of the gall-duct other methods are of value.

My own experience in the operative treatment of gall-stone has been limited to twelve cases, eleven of these being women, and one man. The proportion shows the far greater frequency with which the disease is apt to occur in women. Besides these, two men came under my observation who were suffering from gall-stone, and in both cases operation was clearly indicated; both patients, however, refused operation and I lost sight of them. In the case of women, the influence of pregnancy was plainly discerned. All of them had given birth to children, and many gave evidence that the gall-stone colics appeared in connection with their lying-in period; although they frequently only recognized them as "cramps." In six cases there was a dropsy (hydrops) of the gall-bladder associated with frequent colics. Operation revealed stone in five of these cases, but no concremental formations whatever in one (Case VI). Four of the patients suffered with empyæma of the gall-bladder. In three of these cases stones were formed, but not in the fourth case (Case VIII). Finally, three of the patients suffered from occlusion of the ductus choledochus (one of these suffered also from suppuration of the gall-bladder and liver, and was operated upon twice). Of those operated upon three died—one case of occlusion of the gall-duct from gradual weakening (Case XII), another similar one from suppuration of the liver which had existed prior to operation (Case XIII), and the third death in a case of empyæma of the gall-bladder with stone, from carcinoma and suppuration of the liver, (Case IX). So far, therefore, I have had no death occur from the effects of the operation. I was able to dismiss all my patients without any biliary fistulæ and indeed, with a normally acting gall-bladder, although in some cases several operations were performed.

The operation of cholecystotomy was performed several times—once in a case of dropsy of the gall-bladder with stone, performed at one sitting, (Case I); four times in empyæma of the gall-bladder (Cases VIII to XI), at one sitting; twice in occlusion of the bile-duct as a preliminary operation in cholæmia (Cases XI and XIII), at two sittings. It will be seen, therefore, that I have performed the operation five times at one sitting, and twice at two sittings.

The last modification—the performance of the operation at two sittings—has been especially recommended by Riedel. I prefer the operation as performed at one sitting when it is possible, and would only resort to the double operation when (as in Case XII) the gall-bladder is so shrunken that it is difficult or even impossible to sew up this organ, or when its walls are quite fragile, or appear so thin, that it would seem that they could not hold the stitches. If the gall-bladder can be well reached and drawn into the wound, and if its walls are strong, I strongly favor the single operation. After puncture of the frequently tense and distended gall-bladder, in order to relieve the pressure against its walls, a hermetic closure may be effected. The line of incision should first be coated with iodoform-collodion, or covered with iodoform vaseline upon a piece of lint. After this one way safely cut the gall-bladder open and empty it of its contents. I believe that, if it is possible, without danger to the patient, we are justified in completing an operation at one sitting, it should be so performed, and secondly in certain cases (such as empyæma, possible necrosis

of the walls of the gall-bladder, and occlusion of the choledochus) a delay of several days is by no means a matter of little importance. The biliary fistula occurring in cases I and IX was closed plastically after a time, by means of loosening the walls, suture of the same, and covering the whole with the abdominal walls. In Case VIII the wound closed spontaneously, in Case XI the fistula was removed by establishing a communication between it and the intestine. Three of the patients died in consequence of the primary disease.

The secretion of gall—as is well known—does not occur continually, but periodically, and is especially copious a few hours after meals. Some patients apparently secreted no gall during the day time, while the flow was copious during the evening and night. Contrary to Naunyn's opinions, I have given Karlsbader salt (1 teaspoonful of the salt in half a pint of water) and salicylate of soda (2 to 3 grammes in water), in two cases of occlusion of the gall-duct, and in many cases of simple biliary fistula and have observed a decided increase in the secretion of the gall. I would ascribe to these remedies a decided cholagogue action.

I consider the operation of cholecystotomy the most rational procedure in empyæma of the gall-bladder, in diseases of the walls of the gall-bladder, and, further, in occlusion of the choledochus in order to establish an exit for the bile and save the patient from cholæmia.

In simple concremental formation in the gall-bladder, unaccompanied by any disease of its walls, and where the gall duct is not occluded, I prefer a simple opening of the gall-bladder, emptying its contents, and subsequent closure of the incision—the so-called "ideal cholecystotomy." This operation was performed by me in five cases (Cases II to VI).

After the opening of the abdomen over the distended gall-bladder—and for this purpose I prefer a transverse incision parallel to the ribs, rather than a longitudinal incision, since the former gives a better field of vision to the operator—the bladder and duct are carefully and directly examined by digital palpation, and any adhesions which tend to render the examination difficult, loosened. Then the gall-bladder is drawn forward as much as possible, and the abdominal cavity completely protected by sterilized or iodoform gauze, which is plentifully packed around the bladder. By means of puncture with the exploring needle, the character of the contents of the gall-bladder is determined, and if the fluid drawn up into the syringe is not putrid, and contains no pus, then the patient is inclined somewhat towards the right side, and the gall-bladder incised and emptied of its contents. The stones are usually washed out with ease, or may be removed with the "stone-spoon." Difficulties are met with if the stone is wedged in the cyst, and these are only removable after considerable effort and great pains on the part of the operator. For this purpose the blunt hook will frequently be found a valuable instrument. In one case (Case III) the stone was lightly wedged in the cyst and all efforts at removal were unavailing. Finally, I inserted my finger under the gall-bladder in the abdominal wound and executed a pressure, as though I were squeezing a cherry-pit out of the fruit. The stone was thus easily removed. It will be readily seen that in this case if the abdominal cavity had been closed by suture to the gall-bladder this procedure would have been rendered most difficult, or indeed impossible. The possibility of such an occurrence points, in my mind, to the superiority of this operation over the "ideal cholecystotomy." After the removal of the deepest stones the golden-yellow bile will appear in the bladder, showing that the communication with the liver is now free. In every case I have endeavored to sound the ductus cysticus, but the sound is always caught in the folds of the mucous membrane unless the duct has been very much distended by the presence of stones. This is easily understood since the mucous folds are in the form of a spiral. So far I have been unable to pass a sound from the ductus cysticus into the choledochus or even into the intestine. It will be seen, therefore, that by means of sounding alone we cannot prove the existence of a free passage, while palpation from the abdominal cavity is a most important aid in determining this.

A free passage through the choledochus—which should be determined before the performance of this operation—can only be proved or disproved by an examination of the fæces, or a digital examination of the choledochus.

After the removal of all concretions from the gall-bladder, the latter should be

disinfected with some solution as little poisonous as possible. For this purpose a one-half per cent. solution of lysol, or a solution of salicylic and boric acids will be found applicable. After this the gall-bladder is washed out with sterilized water, great care being taken to prevent, as far as possible, the fluid entering into the abdominal cavity. If we are convinced that the walls of the gall-bladder are intact, we can then proceed to close the opening with two rows of sutures, similar to those used in suture of the intestines. It will be found, however, that these sutures are more easily applied upon the gall-bladder than upon the intestine, since the walls of the former organ are considerably thicker than those of the latter.

The first row of sutures brings the edges of the incision together, and the second closes the peritoneum over it. Whether one should use the continuous or interrupted suture is entirely a matter of preference; personally I prefer the latter, since I consider that a more exact closure of the wound can be effected. For the suture material I have principally used silk thread, but lately have employed catgut in its place, for the reason that I have found that even when the most stringent aseptic measures have been employed the silk sutures are apt to slough out. When possible, it is well to bring the mesentery over the line of suture of the gall-bladder, and to fasten it with one or two stitches. This membrane becomes so rapidly adherent as to form an excellent protective covering. In the first few cases that I operated upon I fixed, or attached, the peritoneum to the peritoneum at the abdominal wound, for safety's sake, but later abandoned it without incurring any untoward results. In the endeavor to obviate the possible bursting of the sutures of the gall-bladder, Senger and Wölfler have practiced a fixation of the gall-bladder to the abdominal wound, opening it a few days later and emptying its contents; Wölfler would not return, or rather, resink the gall-bladder to its natural position for about nine days. The abdominal wound would be closed all but a few stitches which were left loose. In this opening a strip of iodoform gauze was inserted reaching to the suture of the gall-bladder. After the lapse of four or five days this was removed and the abdominal wound entirely closed. This precautionary measure as a guard against the possible rupture of the cystic suture, can at all events, do no harm. In my experience the gall-bladder healed very rapidly in four cases, in one a small but rapid closing fistula was formed (Case VI).

(*To be continued.*)

NEW OPERATION FOR THE RADICAL CURE OF ABDOMINAL HERNIA.

In a pamphlet (published by I. Artero, Rome, 1892), Bottini says that to attempt to close up, by itself, the passage down which the hernia has travelled, or to block up the external orifice by itself, is a delusion; the resulting resistance is far too weak to withstand abdominal pressure. It is the internal orifice, and this alone, which should be closed (by sutures). This is done by bringing together its margins, without disturbing the anatomical relations of adjoining structures, whether the hernia be oblique or direct. The sac is a secondary matter; it may be excised—all or part—or left, according to circumstances. Whether the hernia be free, incarcerated, or strangulated makes no difference; the methodical closure of the internal opening is the only thing aimed at. The hernia is thoroughly opened up along its length, the aponeurosis of the external oblique, and the fibres of the internal oblique are reflected on a director, and the sac is laid bare, and very carefully and thoroughly isolated. Then the bowel is returned, the sac being incised or not according to circumstances; in congenital herniæ, incision is best avoided. Two Hagedorn's needles armed with catgut are passed, the first from within outwards, embracing not only the free margins of the internal oblique and transversalis, but the aponeurosis of the external oblique; the lower suture passes well into the thickness of Poupart's ligament. Then the needles are withdrawn, and a finger is introduced into the orifice to control the tightness of the threads which are now drawn up. The patient is directed to cough, and if any bulging be felt, a third suture may be inserted; this however, is seldom necessary. After a fortnight, the patient is perfectly cured, no truss or bandage being afterward required. Nine femoral, twenty-one inguinal, and one umbilical herniæ were thus operated on, all with perfect success. —*Brit. Med. Jour.*

PREPARING THE FIELD OF OPERATION; CIRCUMCISION; INTESTINAL OBSTRUCTION; APPENDICITIS.

By DR. R. H. M. DAWBARN,
NEW YORK POLYCLINIC.

Gentlemen:—This patient was presented to you at the last clinic, and you remember a small fatty tumor was removed from the back. The result has not been so good as was expected, for there has been some suppuration, an occurrence which is by no means common here, but still is occasionally met with at our clinics, probably from the necessarily hasty methods adopted for cleansing the field of operation. An investigation carried on at the Johns Hopkins University has shown that the plan of disinfecting the skin at least twenty-four hours before the operation is an eminently wise one, as the microbes lodge in the hair follicles and in the deeper layers of the skin, and are therefore not removed by the ordinary washing just prior to operating. The best results are obtained where the parts are first thoroughly disinfected, and then covered with a wet bichloride dressing for a number of hours. The same investigator found that the usual methods of cleansing the hands failed to sterilize them, and the most approved method of effectually sterilizing the hands is the one which I would recommend you to employ in sterilizing the patient's skin, as it can be done quickly, is very efficient, and is applicable to such cases as those upon which we operate here in our clinics. The method consists in thoroughly wetting the skin with a saturated solution of permanganate of potassium in hot water. This stains the skin black, but the next step, which consists in washing with a saturated solution of oxalic acid, removes this stain, and the process is completed by simply washing off the oxalic acid. I am accustomed to carry in my satchel, crystals of permanganate of potassium and of oxalic acid, which can be readily dissolved in water when wanted. This method is convenient and cheap, and I heartily recommend it to you.

As I have been asked to fill this hour today for a colleague I shall adopt my usual custom under such circumstances, and speak on several topics which are of such practical interest and importance, that certain members of the class have requested that they be given special consideration.

CIRCUMCISION.

First, I shall say a few words about the operation of circumcision. I am a firm believer in doing this operation upon every child. Most genito-urinary surgeons will tell you that the Jews have much less venereal disease than any other race, and this cannot be because they are more virtuous, but because there is much less surface to be infected, and that surface is much less sensitive and liable to abrasion. The great majority of young men, probably ninety-five per cent., indulge in illicit intercourse before they are married, and we may as well face this fact. We hope in our minds that our sons will not belong to this great majority, but we know in our hearts that they most probably will, and hence we should do everything we can to avert the evils connected with such habits of life. The simplest way of doing a circumcision is to slit the prepuce along the dorsum, but I do not usually adopt this plan, as it is followed by great œdema which frightens the friends unnecessarily. I believe in removing all the prepuce except enough to cover the corona, and in doing this, great care must be taken that the mucous membrane be pulled down and cut along with the skin, otherwise you are likely to have the mortification of removing a circle of skin and leaving the mucous membrane intact. Having trimmed the parts nicely, a running catgut suture should be used, and the parts given a coating of iodoform collodion, and then dusted over freely with baby powder. In the adult, there is a tendency to erections, and consequent tearing out of the sutures, and to obviate this, the patient should be given for a day or two before the operation, large doses of bromide of sodium, and after the operation, the penis should be encircled in a coil of small rubber tubing through which cold water is kept running.

INTESTINAL OBSTRUCTION.

I shall next consider a few points regarding the diagnosis and treatment of intestinal obstruction—and first, as to intussusception. It does not necessarily involve the entire calibre of the intestine, and in many of these cases, which are especially frequent among children, a tumor can be felt, most commonly in the ileo-cæcal region. The books usually state that it is oblong in shape, but it is rare that the abdominal wall is thin enough or

sufficiently relaxed to enable you to distinctly map out the shape of the tumor. One well-known writer on children's diseases, says that whenever bloody movements are noticed in children under two years of age, the first thing to be thought of is intussusception, and although it does not follow that every time a child has bloody movements there is an intussusception, the frequency with which this condition is overlooked, justifies the warning which this writer gives. Volvulus, on the other hand, is more frequent in adults than in children, and most commonly involves the region of the sigmoid flexure. It seems rather remarkable that it should be met with in grown persons more often because in children the sigmoid flexure of the colon is proportionately larger than in adults. In volvulus, the obstruction is well marked; not even wind passes it, as a rule. Of course, it is sometimes high up in the small intestine, and then the frequent passages of fæces from below this point might lead you to suppose that the obstruction was not complete.

In most cases of suspected intestinal obstruction, the first thing the average practitioner thinks of is some laxative or cathartic, and he usually begins with a mild one, and then runs through the whole gamut to more and more severe cathartics, until probably he ends by giving some croton oil. Now, aside from the fact that croton oil is a very dangerous remedy, there are other and better ones which will suffice where any cathartic is appropriate. Just think that if the croton oil happens to be retained, what an irritant action it must exert! The only laxative I would use would be some saline, such as Epsom salts, Rochelle salts, or Hunyadi water; and if these did not act as purgatives, they will be gradually absorbed through the wall of the gut, and be excreted through the kidneys, and therefore they do not possess the objectionable features of other cathartics. If such laxatives do not relieve the obstruction, I should next think of a high rectal enema, which may be given in various ways. The plan which I believe to be original with me, consists in warming a siphon of carbonic acid water, attaching a rubber tube to the outlet tube of the siphon, and introducing this rubber tube high up into the rectum. By pressing the trigger on the siphon, you can obtain the effect of both the gas and water under pressure, and this pressure can be easily regulated in the same way. After discussing this subject before the class about two years ago, one of the gentlemen came to me and related a case of severe intestinal obstruction, where after the usual injections had failed, at the suggestion of one of the physicians present, the patient was inverted, and nearly two quarts of glycerine introduced into the rectum with a fountain syringe, and the patient kept in that position for half an hour. At the end of this time, there was a remarkably copious discharge of fæces, and the obstruction was completely relieved. We know that glycerine is a very powerful exciter of peristalsis, and the method is certainly worthy of a trial before resorting to the knife. Another method which I have never tried, but which is recommended, consists in washing out the stomach; it is said to act by exciting peristalsis, and I presume it might be successful in mild cases. We now come to the question of operation. If the patient refuses operation, I would desist from the use of laxatives, and would administer opium or similar remedies, and await events, for one well-known textbook says experience has shown that a large percentage of these cases of intussusception recover. If you do not operate early, you may expect dangerous complications, for there are usually in the later stages, firm adhesions. In both volvulus and intussusception, the best treatment in my judgment is to cut out the affected portion and make an artificial anus, and a few weeks later, operate for the restoration of the continuity of the gut, preferably by intestinal anastomosis. It is a great mistake to endeavor to restore the continuity of the gut at the time of the primary operation, although this was the common practice only four or five years ago. Of course, in advocating early operation in these cases, I take it for granted that those attempting such operations are thoroughly competent to carry out the full technique of aseptic surgery. Where there is much distention of the intestine, it may be necessary to puncture coil after coil of intestine, for, strange to say, you cannot remove any large amount of gas by puncturing a single coil. It is for this reason, that I have given up Senn's hydrogen gas test for intestinal perforation. Theoretically this is a beautiful test, but ex-

perience shows that practically, the test does not always work, as the perforation is sometimes obstructed by a hard mass of fæces. In a number of instances in which this test was successful in revealing a perforation of the intestine, it was found that the inflation of the intestine with the hydrogen gas had caused so much distension, that coil after coil required to be punctured in order to facilitate the subsequent steps of the operation. Finally, in experimenting with this test on the cadaver, I had an experience which led me to abandon it altogether. I had produced several bullet wounds in the intestine, and was endeavoring to inflate the gut with hydrogen gas. I allowed the gas to pass through for sometime, according to the usual method in order to expel all air, but on applying a lighted match to one of the perforations in the intestine, there was a violent explosion which would have been extremely disastrous had the test been performed on the living subject. The explanation of this subject was simply that sufficient air had gained entrance through the perforation to form an explosive mixture with the hydrogen gas. The test, therefore, is both unsafe and unreliable.

APPENDICITIS.

I shall now say a few words about appendicitis, a term which embraces what was formerly called typhlitis and perityphlitis. Dr. Mc Burney claims that in ninety-five per cent of these so-called cases of typhlitis, or perityphlitis the trouble is primarily in the appendix. It was because operations were performed formerly at so late a stage that it is only very lately that we learned that the appendix is not an intraperitoneal viscus. We know now that it has in almost every case a distinct though short mesentery. The common idea that seeds and other foreign bodies of some kind or another are the cause of this condition is a fallacy. Prudden states that he has never found in his large experience a seed or pit, the starting point being almost invariably a fæcal concretion. Normally, the blind end of the appendix is held upward so that it can empty itself by gravity, but in almost every case examined pathologically, the blind end has been found hanging downward, thereby inviting, as you see, the retention of fæcal matter long enough to cause irritation.

As regards the symptoms, the patient has pain and tenderness, greatest at a point midway between the navel and the anterior superior spine of the ilium. This was first described by McBurney, and has been called "McBurney's point." At one time, he claimed that it was pathognomonic of this condition, but we know that this is not true. This point is supposed to be about opposite the apex of the appendix, and hence this is the mid-point of the incision. The symptoms may be briefly summarized as follows: (1) This special point of tenderness; (2) rigidity of the abdominal muscles on the affected side, as compared with those of the opposite side; (3) a drawing up of the thigh on the affected side; (4) the presence of a tumor, provided you see the case sufficiently late, or if the patient be etherized, so that the rigidity of the muscles is overcome; (5) the presence in most cases of a certain amount of fever: and (6) if the pus be present, possibly rigors. On these half dozen symptoms, you can base your diagnosis of appendicitis. The condition of the bowels has nothing to do with the diagnosis, because the trouble is in the appendix, although usually the bowels are somewhat constipated. The degree of fever is also not of much importance. The most important point is, shall we operate whenever these symptoms are present? We all know that many of these cases get well, but unfortunately a great many do not recover. Poultices and iodine accomplish nothing; morphine does harm instead of good by making the patient so comfortable that he will refuse an operation which might save his life. The presence of a tumor would induce me to operate in every case, because that means pus, and you cannot tell by what route it will be discharged; but if no tumor is present, I would operate whenever there is shock, as shown by cold extremities, an abnormal ratio between the pulse and respiration on the one hand, and the temperature on the other. For instance, if the temperature were 101° or lower, the pulse 120 or 130, and the respirations proportionately increased, perforation or threatened perforation is indicated in most cases. Having decided to operate, you must make preparations as for an ordinary laparotomy, as you are going to expose the intestine for several inches. It is very common to find the small intestine covering the field of opera-

tion, and much valuable time is consumed in trying to get the intestine out of the way. The following point in technique will aid you greatly at this stage. Turn the patient over so that he rests with the left side against the bed or table, and the field of operation is uppermost; then seize the edge of the gut in the abdominal opening with a retractor, and draw it forward away from the spine. This will make a cavity into which the intestines will fall out of the way, while the cæcum which has a very short mesentery cannot follow, but must remain uppermost. You next apply two ligatures and cut between them. The mucous membrane and the stump of the appendix should be scraped with a spoon, and the stump disinfected by touching with a drop of pure carbolic acid. If you find adhesions blocking off this portion from the general peritoneal cavity, be most careful not to break them up. If the appendix cannot be readily reached on account of adhesions, I carefully wash out the cavity and pack it instead of breaking up the adhesions. This is very important. Drainage is established anteriorly, either by a glass or rubber tube, with gauze both around and inside of the tube. Only the extremities of the incision are closed, the packing being brought out through the middle portion. The packing is frequently changed, the frequency depending upon the temperature and the amount of the discharge. When suppuration is ended, freshen up the edges of the wound, and unite them by sutures, carefully including the muscles, in order to avoid the liability to hernia. When the accumulation of pus is posterior, make a small opening upon the dressing forceps, close to the ilium posteriorly, enlarge this with the forceps, and draw the drainage tube in from behind, and completely close the anterior wound. This is an excellent method of drainage, because the drainage is assisted by gravity, and the tendency to hernia is avoided.

SPIRITUS OPHTHALMICUS.

This is said to be a remedy of great value in chronic conjunctivitis. The old English writers on ophthalmology used it extensively:

℞ Spiritus camphor.
Spiritus vini gallici.....āā ʒi.
Spiritus lavender.
Spiritus rosemary.....āā ʒij.
M. Sig —Eye spirits, to be used only externally over the closed eyelids.

Communications.

THE SHURLY-GIBBES TREATMENT OF TUBERCULOSIS.*

By E. FLETCHER INGALLS, A. M., M. D.,
CHICAGO, ILL.

The iodine and gold and sodium bichloride treatment of tuberculosis, more commonly known as the Shurly-Gibbes treatment, originated with Drs. E. L. Shurly, of Detroit, and Heneage Gibbes, of Ann Arbor, in the fall of 1890, and was the outcome of numerous experiments which they have made on animals.

Owing to the furor created by the announcement that Koch had discovered a remedy for tuberculosis, some enterprising newspaper men who had heard of Dr. Shurly's experiments, succeeded in obtaining from the report of the Medical Society of Detroit and from the Harper Hospital certain facts with reference to his researches; these facts when amplified and illuminated by the brilliant imaginations of the reporters, made many columns in the daily press, which were sent out to all parts of the country. The craze over Koch's tuberculin kept alive the interest in Shurly's treatment and caused numerous physicians in various parts of the country to give it a trial.

In the early part of January, 1891, I visited Detroit to investigate Dr. Shurly's method and was so favorably impressed by the result of his experiments upon animals and the apparent improvement of a number of patients who had been treated upon the same principle, that I returned home and at once began the use of these remedies, with nearly all of my phthisical patients. Since that time I have treated in private practice over two hundred cases of pulmonary phthisis, many of whom have received this treatment. Not wishing to subject these patients to the chance of experiment, I carried out the treatment thoroughly but only as an adjunct to other measures, which seemed to me suitable. Indeed during all my subsequent use of this form of medication, it has been so associated, and therefore the results of

*Read before the American Climatological Association, at Richfield Springs, New York, June 23, 1892.

treatment cannot be ascribed wholly to the iodine or gold and sodium bichloride; however, the outcome of these cases has appeared so much more favorable than those treated by other methods alone that they seem to me worthy of record and sufficient to give a fair basis for estimating the true value of this method.

In the beginning I recommended the treatment for nearly all patients, but after a short time I became convinced that it was of no great value in advanced cases, and ceased to employ it excepting in cases which had not progressed beyond the second stage of the disease; as a rule, I have not since recommended it in cases where the disease has extended beyond the upper lobe of one lung, even though cavities had not yet formed. A considerable number of these patients I have seen but a few times, some not more than once, and in many instances only a few hypodermic injections have been employed; therefore only comparatively few of the two hundred cases can properly be considered in studying the effects of the treatment.

As nearly all patients suffering from phthisis consider themselves better and often appear better for the first two or three weeks under any new treatment or that recommend by any new physician, I have excluded from my list for analysis all cases except those in whom the treatment was continuously employed for more than five weeks. Of these I find very complete records of forty-three, an analysis of which will, I believe, enable us to form a fair estimate of the influence of the treatment upon the progress of tuberculosis. Although the effect of other remedies can not be excluded, I feel safe in the assertion that many of these patients have done much better than former experience would have led me to expect; and I believe these results are largely due to the tonic and alterative effects of the iodine and gold and sodium bichloride. I am confident that none have been injured by the remedies. In the following list I have presented all cases of pulmonary phthisis treated in this manner for a period of five weeks or more without regard to the origin, stage, course or result of the disease. Of the forty-two cases which I shall report many received no benefit; several were apparently benefited for a short time in a way that could hardly be accounted for by mental impressions; quite a large percentage were much improved for several months, and in eighteen per cent. the disease appears to have been arrested. I have classified as arrested all those cases in which the progress of the disease in the lungs has been checked for several months, in which the general health continues good, and the cough and other symptoms have nearly or quite disappeared. I think it probable in all such instances careful physical examination would still reveal evidences of consolidation, though to much less extent than when the treatment was commenced.

In some of this list of cases the diagnonis has been based upon the symptoms and physical signs only, there having been no microscopic examination of the sputum, and a few have been diagnosticated as tubercular, even though microscopic examination failed to detect tubercle bacilli. In some of the cases, classified as arrested, the bacilli may still be found when purulent sputum can be obtained; in others it has been impossible to obtain sufficient sputum for examination, and in still others the bacilli cannot be found. The treatment has not appeared to me to destroy or change the appearance of these germs.

In order that each may judge for himself of the probable value of this treatment, I have given concise histories of these cases that I will not read, but which may be examined at your leisure. I have not classed any cases as cured, believing that in a disease like pulmonary tuberculosis, no patient can properly be counted cured, who has not been free from all symptoms and signs of the disease for at least two years.

REPORT OF CASES.

Case 1.—Not benefited. July 8, 1891. Miss F. B. C., aged 21, ill five months. No hereditary predisposition. Symptoms,—soreness in the chest, night sweats, cough, expectoration, and dyspnœa. Usual weight–107 lbs., reduced to 93 lbs.; anæmic, strength fair, never had hæmoptysis, pulse 120, temperature 100° F. Signs,—left lung, in front: dullness from apex, descending as low as second interspace, with numerous mucus and subscerpitant râles extending from apex to base of lung. Posteriorly, similar râles and dullness extending three inches below spine of scapula. Right lung and heart normal. Numerous tubercle bacilli in sputum.

This patient was treated eight weeks and received 24 injections, when it was deemed best for her to go to Colorado. The treatment was continued there for a time, but she died at the end of eight months.

Case 2.—Not benefited. April 24, 1891. Mr. M. H. W., aged 29. No hereditary predisposition. Patient had been ill one year, the disease having begun with pneumonia. Symptoms,—cough and muco-purulent expectoration, amounting to about four ounces daily, weight reduced from 165 to 155 lbs., has had several hæoptyses; strength, appetite and digestion fair; pulse rapid, frequent fever. Signs,—left lung: feeble respiration over the entire lung with marked dullness, subcrepitant râles and exaggerated voice sounds. A large number of tubercle bacilli in sputum. Treated six weeks, received 17 injections. Patient disappeared.

Case 3.—Not benefited. November 30, 1890. Mr. S. J., aged 25, no hereditary predisposition, had pleurisy with effusion three years previously, and at the time I first saw him he had been sick four months. Symptoms,—pain in the chest, failing strength, dyspnœa on exertion, and cough and expectoration; weight reduced from 150 to 140 lbs., appetite fair, pulse 104, temperature 101.5° F. Signs,—left side, slight loss of motion and dullness and subcrepitant râles over greater part of anterior portion of lung; posteriorly similar signs, extending as low as the inferior angle of the scapula. Sputum not examined. About four months after the patient came under my observation, he was placed upon the iodine and gold and sodium bichloride treatment, which was continued for six weeks, but he received no decided benefit.

Case 4.—Not benefited. September 15, 1891. Mrs. H. H., aged 30, no hereditary predisposition, ill eighteen months. Symptoms,—pain in chest, loss of weight and strength, dyspnœa, cough and expectoration; hæmoptysis ten days previously. Pulse 144, temperature 101¾° F. Signs,—larynx and trachea congested; right apex dullness low as second rib; left apex dullness low as third interspace. Subcrepitant râles below left clavicle, numerous tubercle bacilli in sputum. Patient under treatment thirteen weeks; she received fifteen injections and apparently improved for a short time, but obtained no lasting benefit.

Case 5.—Not benefited, September 18, 1890. Mr. J. H. M., aged 29, no hereditary predisposition; had suffered an attack of pneumonia seven years previously, and had been a hard drinker for some years. Had been ill one year. Symptoms—pain in the chest, loss of weight and strength, cough and expectoration; pulse 130, temperature 100⅘° F. Signs—dullness, subcrepitant and mucous râles over the lower half of left lung. About three months later the patient was placed under the Shurly-Gibbes treatment, which was continued for five weeks; during this time he received twenty-three injections. Patient went to Texas, but finally returned and died a few months later.

Case 6.—Not benefited. March 12, 1891. Miss S. P., aged 27, no hereditary predisposition. Patient had suffered from bronchitis and influenza and began coughing two years previously. Symptoms—weak, lost 15 lbs in weight, strength fair, frequent cough with expectoration of a greenish sputum; two hæmoptyses, appetite poor, pulse 96, temperature 99⅘° F. Signs—left apex consolidation, which had progressed to the third stage; right apex consolidation beginning. She was under treatment six weeks; received eleven injections.

Case 7.—Not benefited. April 30, 1891. Mr. S. J. W., aged about 50, lost three sisters with consumption, had himself suffered from pneumonia four months previously, had been sick for four months. Symptoms—pain in right lung, loss of weight 19 lbs, great loss of strength, night sweats, cough and expectoration of viscid yellow sputum, about two ounces daily, no hæmoptysis, appetite was very poor, pulse 120, temperature 100° F. Signs—entire right lung involved, especially the upper two-thirds, left lung normal, numerous bacilli in sputum. Patient was under observation seven months and a half and received from ten to fifteen injections; he subsequently died.

Case 8.—Not benefited. January 3, 1891. Mrs. M. W., aged 28; ill eighteen months; one sister had died of phthisis; patient herself had pneumonia eighteen months previously. Symptoms—pain in left side, lost in weight 33 lbs., dyspnœa, cough, muco-purulent expectoration of about three ounces daily, no hæmoptysis, anorexia, pulse 112, and temperature 100° F. Signs marked. Sputum not ex-

amined. She was under treatment six weeks, and died about nine weeks after her first visit.

Case 9.—Not benefited. January 7, 1891. Mr. B. P,, aged 21; lost two brothers from phthisis; no previous pulmonary disease; ill four months. Symptoms,—loss of flesh, dyspnœa, cough and expectoration, poor appetite, one hæmoptysis. Pulse 100, temperature 98 ⅔ ° F. Signs,—left apex involved low as fifth rib; right lung: feeble respiration over lower lobe. Sputum not examined. Was under treatment eight weeks and received thirty-one injections; died a few weeks after the last visit.

Case 10.—Not benefited. July 7, 1891. Miss Z. H., aged 27. Several uncles and aunts had died of phthisis. Patient suffered from pleurisy three years previously and from influenza about ten weeks before calling upon me. Symptoms—pain over left lung, weakness, loss of weight from 145 to 114 pounds, night sweats, cough and expectoration of from one to four drams daily; appetite fair, pulse 120, temperature 120⅘° F. Signs—dullness, feeble respiration and harsh respiratory sound over upper lobe of left lung low as fourth rib in front and to fifth rib behind. Cogwheel respiration all over left side and feeble respiratory murmur over the lower lobe. Many tubercle bacilli in sputum. She was under treatment six weeks and received 38 injections, but apparently not benefited. She then went to Colorado and was there under the same treatment for a time, but steadily failed and died after a few months.

Case 11.—Not benefited. November 12, 1891. Mr. M. H., aged 40, no hereditary predisposition, or former illness. Symptoms — weakness, diminution of weight from 174 to 157 pounds, night sweats, dyspnœa, poor appetite, cough and expectoration of from two to four drams daily of muco-pus. Pulse 112, temperature 102° F. Signs—dullness over right apex low as fourth rib, with broncho-vesicular respiration low as the third interspace in front, and extending three inches below the spine of scapula behind. Tubercle bacilli in sputum. He was under treatment six weeks, but received no apparent benefit. He then went West where he probably died.

Case 12.—Not benefited. November 5, 1891. Miss L. S., aged 24. She had suffered no previous illness, but one sister had died of phthisis. Symptoms—failing strength, loss of weight from 130 to 104 pounds, poor appetite, night sweats, irregular menstruation, cough and expectoration of from two to three ounces daily of muco-pus; pulse 120, temperature 101° F. Signs—congestion and thickening of vocal cords, slight dullness, and broncho-vesicular breathing low as rib on left side and low as the third interspace on the right. Tubercle bacilli in sputum. Was under treatment about six weeks, but received only a few injections; died about four weeks later.

Case 13.—Not benefited. June 6, 1891. Mr. B. S., aged 21, no hereditary previous pulmonary disease. Had been sick three months. Symptoms—dizziness, weakness, loss of weight from 123 to 104 pounds, dyspnœa, cough and expectoration of muco-purulent matter about one ounce daily, poor appetite. Pulse 118, temperature varying from 98° to 102° F. Signs—distinct dullness over right apex low as third interspace with a few subcrepitant râles all over the upper lobe of that lung. Slight dullness over left apex and a few subcrepitant râles as low as the second rib. Sputum not examined. Was under treatment about five weeks, but grew gradually worse and died about six months after he first came under my notice.

Case 14.—Not benefited. January 28, 1891. Mr. H. D., aged 24, no hereditary predisposition or previous disease. Had been sick about three months. Symptoms—pain in right side, cough, nervousness, anorexia, emaciation, night sweats and fever. Pulse 106, temperature 101⅕° F. Voice very hoarse, dyspnœa, cough and expectoration of about three ounces of mucus daily. There had been no hæmoptysis. Signs—congestion of the larynx and trachea, with dullness over right apex low as second rib, broncho-vesicular breathing, and subcrepitant râles low as second interspace. Sputum not examined. Patient was under treatment eight weeks and received thirty-one injections, but no apparent benefit. Left for the Old Country where he probably died.

Case 15.—Slightly benefited. February 9, 1891. Mr. H. J., aged 20. Father and mother both died of consumption. Had been sick five weeks when first seen. Symptoms—pain in the shoulder and side,

headache, night sweats, weakness and loss of weight from 140 to 130 lbs., pulse 90, temperature 98⅘° at times, but frequently fever. Appetite poor, but digestion good. Signs—slight dullness and feeble respiration over left apex low as the second rib. Patient was under treatment seven weeks and received twelve injections, and at the end of which time he had gained seven or eight pounds in weight. He, however, began to fail rapidly shortly afterwards and no doubt died within a few months, though I have not a record of the termination of the case.

Case 16.—Improved for a time but finally failed. December 26, 1890. Mrs. D. A. E., aged 29. Had been sick about three years, her trouble having dated from an acute pleurisy. Her mother died of consumption. Symptoms—occasional pain in the left lung, very despondent, nervous, losing weight and strength. Pulse 128, temperature 100⅕° F. Hoarse, dyspnœa, severe cough and free muco-purulent expectoration. No hæmoptysis. Signs—showed a large cavity in the upper part of the left lung, with marked dullness low as the seventh rib and subcrepitant râles over the whole lower lobe. Broncho-vesicular respiration at the apex of the right lung as low as the second rib. She was under treatment about seven weeks and received thirty-five injections. She was apparently much benefited at first, but at length began to fail and then went West, where she continued to grow worse until she finally died about nine months after her first visit.

Case 17.—Improved for a time. December 29, 1890. Mr. E. P. F., aged 20. He had been sick two months; no hereditary predisposition, and no previous pulmonary disease. Symptoms—pain in chest, loss of weight from 134 to 124 lbs., loss of strength, night sweats, dyspnœa, poor appetite and digestion. No hæmoptysis; pulse 150, temperature 101½° F. Signs—dullness and broncho-vesicular respiration over right apex as low as third rib, over left apex as low as the fourth rib with numerous subcrepitant and larger râles. Sputum not examined. Patient was under treatment seven weeks, received twenty-nine injections, and was apparently considerably benefited at first, but died within a few months after last treatment.

Case 18.—Improved for a time. July 9, 1891. Mr. M. M. J., aged 16. Two brothers had died of consumption; he had suffered no previous pulmonary disease. Had been sick two months. Symptoms—pain in right side, with loss of weight from 124 to 120 lbs. Very anæmic, night sweats, cough and expectoration, with poor appetite and digestion. No hæmoptysis. Pulse 96, temperature 99½ to 103° F. Physical signs showed involvement of right apex low as third rib, with broncho-vesicular breathing, and dullness in left supra-clavicular region. Sputum not examined. Patient was under treatment five months and was apparently much benefited, but after a time he began to fail and with the coming on of bad weather, went to Arizona. On the way he took cold and continued to grow worse after he arrived at his destination. He remained there about two months, then returned and died about four weeks after reaching home.

Case 19.—Improved for a time. October 7, 1891. Mrs. K. J. F., aged 24, no hereditary predisposition; had pneumonia three years previously. Symptoms—failing strength, loss of weight from 150 to 135 lbs., night sweats, dyspnœa, marked anæmia, cough and expectoration of muco-pus. No hæmoptysis. Digestion and appetite poor. Physical examination showed slight involvement of both apices, numerous tubercle bacilli in sputum. Patient was under treatment seven weeks and was apparently considerably improved at first, but began to lose strength and then went West. She remained for three or four weeks in Nebraska, where she did poorly and subsequently went to New Mexico, but grew continually worse and finally returned at the end of three months, and died shortly afterward.

Case 20.—Improved for a time. May 27, 1891. Mrs. A. B. M.. aged 27. One sister died of phthisis; patient had pleurisy one year previously. Had been sick eighteen months. Symptoms—loss in weight from 135 to 111 lbs., anæmia, dyspnœa on slight exertion, severe cough, and expectoration of about half a pint daily; pulse 114, temperature 101° F. Signs—right side in front, dullness low as the fifth interspace, behind extending one inch below spine of scapula. Respiration slightly harsh over this dull region and feeble all over the remainder of the lung. Left side in front, slight dullness as low as sixth rib and behind extending

down to the spine of scapula; feeble respiration all over the left lung with a few subcrepitant râles. Sputum not examined. Patient under treatment 22 weeks, and received 55 injections. She seemed very much benefited for most of this time, but as the winter came on it was thought best for her to go to a different climate. She went to Arizona, but caught cold upon the way and did not regain her health, though she improved after a few weeks, but ere long she took the influenza, subsequently grew rapidly worse, and died after a few weeks.

Case 21.—Improvement for a time. February 6, 1891. Mr. R. S., aged 23, had been sick for seven months; no hereditary predisposition, and no previous pulmonary disease. Symptoms—pain in the throat, cough and expectoration of purulent sputum, poor appetite and loss of weight and strength. Signs—larynx congested and thickened, but no ulceration. Dullness and broncho-vesicular breathing low as the third interspace on the right side and similar sounds over the very apex of left lung. Numerous tubercle bacilli in sputum. Pulse 132, temperature 99½° F. Patient was under treatment 11 weeks, receiving 33 injections, and was very greatly benefited. When last seen he was in better health than in the beginniug, but I do not know the subsequent history of the case.

Case 22.—Improved for a time. January 8, 1891. Miss P. B., aged 21. Had been sick three months. Her mother and one sister had died of consumption; no previous pulmonary disease. Symptoms, —pain under the sternum, loss of weight from 128 to 124 lbs. Strength fairly good, pulse 132, temperature 102° F., night sweats, dyspnœa on exertion, severe cough in the morning with expectoration of light greenish sputum in small quantities; no hæmoptysis. Appetite good and digestion fair. Signs—dullness over right apex marked as low as third rib, and broncho-vesicular respiration in the same region. A few subcrepitant râles over the lower lobe of right lung, and feeble respiration over whole of this lobe. No distinct signs on left side. Sputum not examined. She was under treatment five months and received 65 injections. Two months after treatment began it was noted that she was gaining strength, her pulse was diminishing in frequency and her temperature was lower. Two months later there was less cough, but the temperature had slightly increased. About this time diarrhœa began and continued in spite of any form of treatment. She gradually failed and died after a few months.

Case 23.—Much improved for a time. March 11, 1891. Mr. C. H., aged 31. No hereditary predisposition and no previous pulmonary disease. Had been sick six weeks. Symptoms—loss of weight and strength with cough and expectoration of muco-pus. Pulse 114, temperature 98⅘° when first examined. Physical examination revealed distinct signs of consolidation low as second rib on right side, with feeble respiration low as fourth rib and slightly enfeebled respiratory murmur over the whole right lung, Tubercle bacilli in sputum. Patient was under treatment five months, received 33 injections, and apparently was very greatly improved. The patient, however, knew that he had consumption and had frequently stated that he would never die of that disease, intimating that he would take his own life. He called a physician suddenly one evening under peculiar circumstances seeming to indicate that he had taken aconite or some other violent poison from which he died in about five minutes.

Case 24.—Improvement for a time. January 31, 1891. Mr. K. C., aged 24. No hereditary predisposition, and no previous pulmonary disease. He had been coughing for about four years. Symptoms—dyspnœa, weakness, chills and fever of three weeks duration. Pulse 130, temperature 101° F. Physical examination showed marked involvement of right apex as low as seventh rib and with numerous tubercle bacilli in sputum. Patient was under treatment 15 weeks, received forty-four injections, and was apparently greatly improved for some time, being able to go on with his work, notwithstanding the severe epidemic of influenza, which caused four-fifths of the numerous other clerks in the office to lay up for some time. Eventually the patient began to fail and concluded to go West. A subsequent history of the case I have not obtained, but have no doubt it proved fatal.

Case 25.—Much improved for a time. October 11, 1891. Miss S. K. M., aged 24. Her mother died of phthisis; the patient had suffered no previous pulmon-

ary disease, but had been coughing for six months. Symptoms—pain in the chest, weakness, anorexia, loss of weight from 133 to 95 lbs., night sweats, considerable cough, but no expectoration. She was markedly anæmic, pulse and temperature were noted as normal. Physical examination revealed much depression of the upper part of the sternum and infra-clavicular regions, but this had existed since childhood. Dullness over right apex as low as the second rib in front and behind, extending to the spine of scapula. Broncho-vesicular respiration and subcrepitant râles with feeble respiratory murmur in the same region. Numerous tubercle bacilli in sputum. She was under treatment for six weeks, received the injections regularly, and greatly improved in her general condition. With the coming on of the worst portion of the winter she went to the City of Mexico, when shortly after her arrival she took a severe cold and from reports seems to have had pneumonia, at any rate she did poorly for a number of weeks, but finally began to improve. At present she is said to be gaining.

Case 26.—Mr. L. E. J., came under my care January 27, 1891. Much improved for a time. There was no hereditary predisposition. He had suffered previously with bronchitis, and had been sick for about two years. Symptoms—pain in chest, weight diminished from 154 to 149 lbs, cough and slight expectoration; never had hæmoptysis. Physical examination showed a small tubercular ulcer in the larynx and consolidation of the right apex, low as third rib. There were numerous tubercle bacilli in sputum. He was under treatment five weeks and received 45 injections, during which time he steadily improved, continuing at his work. When last seen, nine months later, he was much better than when he first consulted me.

Case 27.—Much improved for a time. August 1891., Mr. M. S. J., aged 20. A brother had consumption; the patient had suffered from bronchitis; had been sick four months. Symptoms—anorexia, emaciation, loss of strength, night sweats, cough and expectoration; Never had hæmoptysis; pulse 102, temperature 101½° F. Signs—left apex, slight dullness above clavicle with sticky subcrepitant râles and increased whisper resonance. Tubercle bacilli in the sputa. He was under my care seven months, receiving the injections quite regularly for four or five weeks, subsequently about two or three times per month; during this time he was very much improved and when seen about two months ago was much better than any time before since he first came under my observation.

Case 28.—Much improvement. July 10, 1889, Mr. K. L. J., aged 26, came under my care. His father had died of some pulmonary disease, and the patient had been troubled with his present illness for two years. He was nervous, had lost some in weight and strength, was short of breath on exertion, and sometimes had severe cough, expectoration of about an ounce of yellowish matter daily. Never had hæmoptysis. Signs—dullness over left apex low as fourth rib in front, and behind over whole of left lung. Respiratory sounds feeble with râles, most distinct over the lower lobe of the lung, and broncho-vesicular respiration at the apex. Right lung normal. About the 1st of January, 1891, he was placed under the Shurly-Gibbes treatment, which he received regularly for two or three months and since that time he has received the injections about two or three times per month, all told amounting to 106 times. A large number of tubercle bacilli in sputa. The patient has held his own during all this time, though he has not really gained, yet considering the nature of the disease it must be considered an improvement. He is still doing well.

Case 29.—Much improved, December 12, 1891. Miss D. N., aged 28, no hereditary predisposition or former disease of the lungs. She had been sick for one year. Symptoms—loss of weight from 110 to 95 pounds, very weak, hoarse, dyspnœa, cough, appetite poor and fingers clubbed. The pulse was rapid and she had a temperature from 102° to 103 ° F., had had two hæmoptyses. Signs—slight depression over the right apex, with deficient movement and some dullness low as the third interspace. In the same region broncho-vesicular respiration as low as the second rib in front and extending one half inch below the spine of scapula behind. On the left side respiratory murmur slightly harsh above the clavical, no râles. Patient was under treatment six months and received forty-three injections, and was much improved. Fever disap-

pearing entirely and the cough almost ceasing. She is still doing well.

Case 30.—December 16, 1891, Miss O. R., aged 17, no hereditary predisposition and no former disease. Symptoms—poor appetite, loss of weight and strength, hoarseness, cough and a little expectoration. Never had hæmoptysis. Pulse 120, temperature 99°. Signs—arytenoid cartilages much swollen, dullness over right apex as low as the second rib, very distinct above the clavical. Exaggerated vocal resonance in the same region, with broncho-vesicular respiration above the clavical; no râles. No tubercle bacilli were found in the sputum. She was under treatment for three months and apparently had nearly regained her health though she still remained hoarse. During the latter portion of treatment she was under the care of her family physician. At the end of three months I advised that the injections be discontinued, but she speedily began to lose weight and strength, and they were then renewed with favorable results. At last report she was still doing well.

Case 31.—March 17, 1891. Much improved, Mrs. M. R., aged 21, no hereditary predisposition, had an attack of pleurisy about three months previously. Symptoms,—soreness in chest, loss of weight and strength, hoarseness, and great dyspnœa on exertion; cough and expectoration of about four drams of yellowish sputa daily. Had hæmorrhage two years previously and slight hæmoptysis several times since. Appetite good, pulse 108, temperature normal. Physical signs—right arytenoid much swollen with a papillary growth on its anterior surface; dullness and harsh respiration over the left apex, and numerous tubercle bacilli in the sputa. She was under treatment two months but received the injections regularly for only a short time. She improved much and at last accounts was doing well.

Case 32.—Much improved. November 7, 1891. Mr. F. E., aged 29, no hereditary predisposition to phthisis. Symptoms—emaciation, hoarseness for the last two years, occasionally slight expectoration of blood. Pulse 88 but said usually to be slower. Temperature ranged from 98 6-10 to 99 4-10° F. Dullness over right apex. low as second rib, broncho-vesicular breathing, as low as third interspace and a few sticky subcrepitant râles, with many tubercle bacilli in sputa. He was under treatment about three months, receiving however, only a few injections. He gained several pounds in weight, and at the end of this time the temperature and pulse, were normal, there was little or no dyspnœa and but little cough.

Case 33.—Much improved. April, 1888. Mrs. W. N. N., aged 26, no hereditary predisposition and no previous pulmonary disease. She had been coughing for about two months when first seen. Symptoms—pain in the upper part of the left chest, with slight loss of weight, and occasional cough and expectoration of from two to five drachms of muco-purulent matter; had slight hæmoptysis six months previously. Appetite and digestion fair. Physical examination showed slight thickening of the arytenoid cartilage with deficient movement of the apex of the left lung and dullness as low as the third interspace. Broncho-vesicular respiration and exaggerated vocal resonance with a few râles over the same area and extending a trifle lower. There were also a few subcrepitant râles over the apex of the right lung. This patient improved under treatment and finally appeared practically well, but at length during the course of gestation the disease was lighted up anew, and after confinement she ran down rapidly, cavities formed in the lungs, and at the earnest solicitation of her friends, though without the advice of her medical counsellors, she went to California. After a time she improved, but during her residence there she had an attack of what appears to have been tubercular meningitis lasting for several weeks. She subsequently grew better and spent the early part of the winter of 1890 and 1891 in Texas, but about the middle of January went to New Mexico and near the first of February, 1891, began the Shurly-Gibbes treatment. She began to improve coincidentally with the treatment and steadily gained, making remarkable progress the next two months. She then went to Colorado and continued the Shurly-Gibbes treatment, the injections being given less frequently for many months. She is still doing well. This was a desperate case when she went to California and her improvement since has been phenomenal. When the Shurly-Gibbes treatment was commenced she was using about twenty handkerchiefs per day to receive the

abundant muco-purulent expectoration, but at the end of two months a single handkerchief would suffice. Microscopic examination showed a large number of tubercle bacilli in the sputum. Although the benefit in this case must be attributed largely to the climate, yet the rapid improvement was coincident with the use of the Shurly-Gibbes treatment, and it has always appeared to me, as it has to her friends, that it had very much to do with the arrest of the disease. This is the only advanced case of tuberculosis in which I have seen any decided benefit which could be attributed to this form of treatment.

Case 34.—Much improved. September 1891. Mr. S. G., aged 31, no hereditary predisposition to tuberculosis and no previous pulmonary disease. Patient had been ill for several months when I first saw him and had just suffered a hæmoptysis. This patient was under my care for three years before the Shurly-Gibbes treatment was commenced. In February 1890, there was distinct consolidation of the apex of the right lung as low as the third rib. In June of the same year he was slightly improved but in September was again worse. He returned to Chicago after a prolonged absence during the fall of 1891 and desiring to remain in the city, I decided to place him under the Shurly-Gibbes treatment. Numerous bacilli were at this time found in the sputum. His general health was fairly good and his weight as great as at any time since I had known him. Treatment was begun on September 10, 1891 and continued, the injections being given about twice a week for several months. The patient apparently improved under the treatment and was able to attend to his work all winter long. During the latter part of the winter he was so well that the treatment was discontinued, but he soon began to fail and the treatment was renewed with decided benefit. He continued to do well until about six weeks ago when he began once more to fail, and I now find that the disease had again been lighted up in the lung so that I have directed him to seek a different climate.

Case 35.—Disease arrested January 13, 1891. Mr. M. T. J., aged 24. He had lost one or two aunts with tuberculosis, and had himself suffered from catarrhal pneumonia the winter previously and had been sick for two months when I first saw him. Cough and expectoration of a considerable quantity of muco-pus, pulse 124 and temp., 100 3–8° F. No hæmoptysis, had a fairly good appetite. No examination of the sputa. Signs—right apex dullness and harsh respiration low as second rib in front; similar signs behind extending to within one inch of the spine of scapula, no râles. Feeble respiration over the lower lobe of right lung, having only about 60 per cent. of the intensity of the left side. This patient was under treatment 11 weeks and received 24 injections. At the end of the time he appeared perfectly well and has so continued with the exception of one or two slight colds.

Case 36.—Disease arrested February 17, 1891. Mr. B. W. J., aged 29. The patient had at this time been coughing for four weeks and had recently raised blood; there was no hereditary history of tuberculosis and he had never suffered from any previous pulmonary disease excepting bronchitis. The weight was nearly normal, strength fair, pulse 96 and temp. 99° F. The sputum which amounted to about two ounces daily, consisted of muco-pus, and contained tubercle bacilli. Signs—loss of motion and dullness over left apex low as second rib, with indistinct subcrepitant râles. He was placed under treatment several weeks during which he received 36 injections; at the end of this time he appeared perfectly well and has continued in this condition ever since, with the exception of two or three slight colds, which have caused him to cough more for a few days at a time. Tubercle bacilli continue in the sputa, though his general appearance is that of a person in perfect health.

Case 37.—Arrested May 9, 1891. Mr. S. G., aged 22, no hereditary history of tuberculosis and no previous pulmonary disease. He had been ailing for a year and a half. His flesh and strength remained good, appetite fair, there were no night sweats, but he coughed and expectorated about an ounce of muco-pus daily. Pulse 114 temp. 100 $\frac{3}{5}$ ° F. No distinct dullness could be discovered, but there were occasional râles all over the upper lobe of the left lung. He was under treatment nine months during which time he received 65 injections. He gained much in weight and strength and at the end of this time appeared perfectly well and he still remains in this condition, though at the last ex-

amination bacilli were still found in the sputum.

Case 38.—Arrested November 12, 1890. Miss S. R., aged 24. Her father died of consumption. She had been sick about three months. Symptoms—pain in the chest, emaciation from 145 to 122 pounds, weak, a hacking cough and muco-purulent expectoration; pulse 102, temperature 99½° to 103° F. Signs—marked dullness and broncho-vesicular respiration above the right clavical. No microscopic sputa. She was under my care for eight months, during which time she received only 11 injections, these being made at first about once a week. She received other treatment at the same time as did all other patients, so that the effects of the Shurly treatment cannot be definitely estimated. At the end of the treatment she appeared perfectly well and she continues so at the present time, having gained in flesh and lost high temperature and cough. Although the history of this case is not complete, yet those who saw her during the course of the treatment have no doubt of the nature of the disease.

Case 39—Disease arrested July 17, 1891. Mr. K. P. C., aged 27. There was no hereditary history of consumption. Symptoms—pain in the chest, cough and slight muco-purulent expectoration with dyspnœa upon exertion. Appetite fair, and strength good, pulse and temperature not noted; had suffered six hœmoptyses. Signs—dullness over right apex low as second rib in front and behind extending two inches below the spine of scapula, marked broncho-vesicular respiration in the same region and subcrepitant râles. She was under my care for seven months during which she received 58 injections and at the end of that time she appeared perfectly well and so continues at present.

Case 40.—Disease arrested August 26, 1891. Mr. T. G., aged 34. No hereditary history of tuberculosis. He had diminished in weight from 133 to 128 pounds, but had a fair appetite and digestion, was troubled considerably with cough but had only slight expectoration. Had raised four ounces of blood about one month previous. Pulse 78, temperature 99 2-5° F. Signs—harsh respiration over apex of left lung low as second rib, but no râles and no distinct dullness. A large number of tubercle bacilli in sputa. He was under my care for six weeks, during which time he received 18 or 20 injections. He then went to Colorado and the treatment was continued by Dr. Hart of Colorado Springs. He slowly improved and finally returned to Chicago in apparent perfect health and so continues at the present time. In this case climate might be given some of the credit, but the patient himself attributes the beginning of his betterment to the treatment. The bacilli have disappeared from the sputa.

Case 41. Disease arrested December 23, 1890. Mr. N. F. C. aged 27. Hereditary history showed numerous deaths in the family of tuberculosis. He had suffered from pneumonia twelve years previously, and had been ailing four months when he first called upon me. Symptoms—pain in right side with cough and free expectoration, strength and appetite fair. Pulse 102° F. There had been no hæmoptysis. Signs—dullness over the inner one half of the right infra-clavicular region with prolonged respiratory murmur and exaggerated vocal resonance but no râles. Similar signs were obtained in the supra-scapular region of the same side. Numerous tubercle bacilli in the sputa. He was under my care for nine months, during the early part of which he received twenty-two injections, which seemed to give him decided benefit. Sometimes he experienced a tonic effect from the injection for thirty-six hours after it had been given. At the end of the time he appeared perfectly well and has so continued ever since, with the exception of two or three slight colds lasting for four or five days each. He still continues in good health. Disease arrested.

Case. 42.—Disease arrested January 14, 1891. Miss H. M., aged 27. No hereditary predisposition or previous pulmonary disease, but had been coughing for three months. Symptoms—pain in chest, weakness, fever, cough and expectoration of muco-purulent matter. There had been no hæmoptysis. Pulse 78, temperature 99⅘° F., but subsequently frequently as high as 101° or 102° F. All the symptoms indicated rapidly progressing tuberculosis. Signs—Dullness over right apex as low as third rib with harsh respiratory murmur. She was under my care thirteen weeks during which she received thirty injections. At the end of the treatment she appeared well and she continues so at the present time. In this case the sputum was not examined, but the symptoms and physical

signs as witnessed by my assistants and myself leave no doubt as to the diagnosis. Several others of those for whom I have recommended this treatment who have been taken care of by other physicians have apparently been much benefited by it. Three of these were treated by Dr. Walters of Woodstock, Illinois, who reports very great improvement or arrest of the disease I have not included them in this report. When I first began the use of the Shurly-Gibbes treatment, I gave it to all phthisical patients who came to me, but in many instances only one or two injections were given, and often the patient was not seen after the first or second visit, as many of them came to me from a distance and soon returned to their homes.

An analysis of these 42 cases, will show that 14, or one-third, received no apparent benefit, but it will also show that twelve of these were far advanced when they first came under my care. Fourteen others were apparently decidedly improved for some time but ultimately they grew worse, and six of them have since died. Of the 14 cases that were not improved, I believe that all are dead. Six of the 42 cases are noted as much improved, all of them have been under observation for many months, and I believe that they are, with one exception all doing well at present. Four of these when first seen were in the early stages of the diseases having been ill but a few months and some of them will probably recover. Of the 42 cases eight are noted as arrested. All of them are at present in good health, though in those where the sputum has been examined recently, of which there are four, the bacilli continue and in all these four, and possibly in others there is still expectoration of a small amount of muco-purulent sputa every day, amounting possibly to half a dram.

It will be seen that whatever the results of the treatment, it does not destroy the tubercle bacilli, a fact which was established early by Dr. Shurly himself. During the last few months I have discontinued the use of chlorine as an inhalation substituting for it in most instances inhalations of iodine, which has seemed to me more beneficial.

It will be seen by the analysis that a little more than 19 per cent. of the disease has been arrested. In about 14 per cent. the patients have been greatly improved, and in 33 per cent. they were apparently benefited for some time, though they ultimately failed. It will be noticed also that nearly all of the patients who were not benefited, were already far advanced in the disease, when first given the treatment; and that the majority of those who have been treated in the inception of the disease have been greatly improved or have recovered. But it will also be observed that the treatment is not entirely valueless in some advanced cases. Considering these facts, I think that I am justified in believing that we have in the Shurly-Gibbes treatment for tuberculosis, a method of great value in incipient cases, which adds much to their chances of recovery. I do not think we should rely upon it alone in any case, but for myself I would feel that I had not done my patient justice if I had not given him the benefit of its trial, providing the disease of the lung had not extended below the third rib, when he first came under my observation. While the treatment may occasionally prove beneficial in advanced cases, I would not recommend it to such patients excepting where they desired to try it after the chances have been fully explained. In only one of the cases reported was a history of previous syphilis obtained, and this case was so clearly tubercular, that I did not hesitate to place it in this list; but it is at once apparent that where doubt as to the tubercular or specific origin of pulmonary disease existed, this would be an appropriate treatment for trial.

36 Washington St.

SYRINGES FOR SUBCUTANEOUS INJECTION.

The *Journal de Médecine et de Chirurgie pratique*, 1892, 2e. cahier, p. 49, gives full and accurate information concerning the syringes of Malessez, Félizet, Gimbert, Burlureau and Guerder, and Peter. The last three forms possess especial interest, in that the treatment of tuberculosis by injection of medicated oils (creasote 1 to 14, iodol iodoform 1 to 29, crystallized phenic acid 1 to 49, or guaicol) is now recommended. The technique is fully given, the accidents carefully stated, precise antiseptic precautions noted, and, taken as a whole, this paper is a complete guide to the practice of voluminous subcutaneous injections.

SEPSIS, WITH A NARRATION OF A FEW INTERESTING AND INSTRUCTIVE CASES.*

By ROBERT PETER, M. D.,
CANAL DOVER, OHIO.

1. In these blessed days of antisepsis, thanks to Pasteur, Lister and Koch, we are at least permitted to come to our patients with *clean hands and a clear conscience.* These sanitary precepts are founded upon the dire lessons of sepsis. This dread process is the dispenser of the admonition—"Let another man's shipwreck be your seamark." And yet, how little is its intimate nature understood. It would seem that this were still largely an unexplored field in which much work need be done.

2. Our theme therefore is not so easy to define. A septic process is so complicated that a number of complex factors must necessarily enter to produce it. That stage in our knowledge is not yet at hand, that we can fully appreciate all these factors so curiously inter-woven in their relations to each other, as they are concerned in sepsis. However, it may be briefly defined as infection and intoxication, which arise when specific, pathogenic germs gain access to the body, and finding conditions favorable, they grow and multiply therein, and in so doing elaborate a chemical poison which induces characteristic effects. These effects are sometimes only local, or both local and systemic; this will often only depend upon the kind of germ, or, both upon the kind of germ and the kind of host.

3. It is in physical life, just as it is in social life, the lower grade is striving to oppose the higher. *Instability* of organized structure and function during life, as well as of organic material after death, make bacterial life possible. Under these circumstances organized form falls prey to bacterial life's action, by which means it is returned to its primary or inorganic state, from whence it was taken. In this process *the transition products necessary to septic intoxication are given.*

4. In a scientific way this fact was first proven by Panum it 1856. He showed that poisons comparable to venom of serpents, curare and nicotine and not to be destroyed by either boiling or evaporation, are formed during decomposition of animal matter. Since his time Brieger deserves credit for isolating a number of these putrefaction ptomaines; and, what is still more important, he was the first one to demonstrate the fact that certain poisons are also formed within the living body, by certain germs causing infectious diseases. Hence it is evident that every germ which causes disease in man does so by virtue of its chemical products. These poisons may result first from the secretion by some of the bacterial cells themselves; secondly, from the splitting up of complex compounds of organic source by the activity of bacterial life.

5. Ever mindful in her conservatism, nature provides a restorative process, to regenerate tissues impaired by traumatism and disease. It resembles in every respect the physiological process of growth of tissues, just as is observed during development of the body; and, like in other development processes, more or less heat is evolved. Embryonal cells promptly undergo transformation into tissues which correspond to the anatomical seat of lesion. Unmolested, this process *never* proves destructive, but *always constructive*; and, it ever promptly attains its end. However, molested by bacterial life, a process *never* constructive, but *always destructive*, is inaugurated; and *abnormal* heat is generally evolved. Embryonal cells are *not* promptly, and more often *not at all*, transformed into tissues corresponding to the seat of lesion; but, are broken down and appropriated to the formation of poisons which are utilized in intoxication. This complicated process *never* promptly attains a salutary end, but only too often destroys the host.

6. Narrative No. I. somewhat uniquely illustrates virulence, an old and only too oft-told story:—Mrs. ——— is on a journey of several hundred miles; while on the train she is seized with pain and flooding, and, as she puts it, "something drops while in the water closet." After reaching her destination flooding still continues for about one week. Loath to seek advice, failing strength and offensive discharges finally constrain her to do so. On examination the doctor find *os uteri* tightly puckered up; forcibly dilating it, he removes a small amount of débris.

*Read before the Ohio State Medical Society, at Cincinati, O., May 6, 1892.

Three days thereafter patient takes a violent chill followed by progressive inflammation of the surrounding tissues and involving the pelvic peritoneum. For three days the patient it entirely unconscious, pulse and temperature fluctuate, at times the former ranging over 160 beats per minute and the latter, over 105° F. Writer is called per telegram; on my arrival patient has regained consciousness and is somewhat better. I tell the doctor and his associate, who together are now attending, that the trouble is evidently septic, but this they are not inclined to believe. But, very soon there are thirty-five inoculated *puerpera* in the community; out of which number, Mrs. ———, is the only one who survives. Even one of the physicians becomes inoculated from some one of his patients and he has a very serious time to recover. Mrs. ——— after four years, suffers since from chronic pelvic abscesses.

7. It is of course assumed that infection is always from without. Germs may be conveyed into the body in many different ways. Into mucous channels, for example, they may find their way by inhalation or by being swallowed with the food. True, the hydrochloric acid contained in the gastric juice serves often to protect the digestive tract from infection; but under certain circumstances these invaders acquire an unusual amount of resistance, that they can withstand the action of the stomach's acid secretion, as well as can the spores. After alighting on a mucous or cutaneous surface, the infecting germ furthers its journey into the tissues through a solution of continuity of structure, be it ever so insignificant. It is a noted fact, that infection is even more *often* apt to occur through a merely slightly broken surface that does not bleed, than through a bleeding one; because, in the one case the infecting agent is readily taken up by the absorbents, while in the other, it may be washed away. Germs always follow the avenues of *least resistance*: Some forms find in the blood, others in the lymph spaces and vessels, the conditions most favorable for their proliferation. And even after they do gain access to the body, the same kinds of infecting agents do not always produce like effects on different hosts. Sometimes, in one instance it may prove only a local process, while in another, it may prove both local and systemic. It is believed that this will generally largely depend upon the number in which the invaders are present—i. e., the size of the dose—upon the varying virulence which the same species under different circumstances possesses, as well as the varying capacity of the host's resistance to ingress of the germs.

8. Narrative No. II. Albert K., aged five years, gets his right hand into a pulley, tearing away distal phalanges of the little and third fingers, and more or less crushing the whole hand. His wounds are treated with iodoform dressings, yet parts suppurate freely; however, the body suffers no systemic effects. On a very busy day the father brings his boy to my office, to obtain new dressing; to gain time, I request the father to proceed first in removing the old one. In doing so the father runs the tip of his right thumb over the point of dressing pin and barely nicks it. Three days after, he had a decided chill followed by high fever and he is a very sick man. The thumb is very painful and swollen, and progressive, destructive inflammation sets in, that involves the entire hand and forearm. Three incisions are made to draw off the pus; one into the thumb, one each into the hand and forearm respectively. Despite our treatment, the entire belly of flexors of the thumb sloughs away, and the father but very slowly recovers, while the son's wounds promptly heal and he is at the same time enjoying the best of health. This narrative first shows the difference of havoc produced upon the son and father respectively, by the same kind of pyogenic micro-organisms; further, it shows in the father's case the aptitude of infection through an insignificant portal.

9. Both character and degree of infection and intoxication will first depend upon the kind and competency of the infecting agent on the one hand, and secondly, upon the kind and susceptibility of the host on the other hand. These are problems towards which the complex factors of the microbe's individual equation, as well as the complex factor of the host's individual equation, must respectively contribute to solve. Diverse tissue metabolism resulting from the whims of fluctuating nutrition and waste, both during health and disease, must no doubt variously affect the parasite's environment

and, therefore, also its capability, as well as the host's responses to the bacterial reaction. With such variable conditions, chemism and concomitant symptoms must therefore *often* and *widely* differ.

10. Narrative No. III. Mr. E. C. M., aged sixty years, is afflicted with erysipelas involving the face, ears and parts of the neck and scalp; which is accompanied by uncontrollable nausea and vomiting. From Sunday to Thursday the temperature ranges between 100.5° F., and 103.5° F,, pulse between 86 and 96 beats per minute. On Thursday the temperature drops to 86° F. and the pulse to 66 beats per minute, *and at the same time nausea and vomiting cease*, but the local conditions remain about the same. This shows that chemism radically changed on Thursday, and with it did also all of the systemic manifestations, while local appearances are seemingly not much changed.

11. Narrative No. IV. Mrs. S. F., about thirty-five years of age, gets pregnant in August, and her pregnancy is accompanied by uncontrollable vomiting, that she rapidily emaciates and fails in health. It so continues until one week before Christmas, when she aborts. The family physician is called. Patient appears to him rather large for the length of time of pregnancy. An abdominal effusion is noticed by him. The puerperal state in *itself* passes by uneventfully; only vomiting will *not* cease. Writer is called in consultation, and the patient is found *extremely* emaciated and enfeebled, with a very rapid pulse of 144 beats per minute, and a *remarkably vacillating* febrile movement, fluctuating within two hours first from 100.5° F. to 97.5° F. and then to 101° F. The tongue shows two large necrotic patches. The stomach is very irritable, rejecting everything and is distended with gas. The spleen is considerably enlarged, and as already stated there is some abdominal effusion. Close inquiry elicits the fact, that patient had fever for some time before the miscarriage. Vomiting not ceasing, we know that *now* its cause is pregnancy, and from the other data at hand, it appears that our patient suffers from sepsis. The infection must be traced to the *primae viae* and no doubt prior to puerperium. This would illustrate pre-disposing influence of malnutrition and temperature vacillation, characteristic of some forms of sepsis.

12. The entrance of the different bacteria into the body, their residence there, and their means of support result in different processes. Some of these processes are always local, and never more, as in gonorrhœa (?), infectious ophthalmia, etc. There are some in which local evidence is almost *nil*, while the systemic manifestations are alarming, as in tetanus, la grippe, etc. These, no doubt, are constant biological stipulations. While again, we have to deal with some bacterial processes which are not constant in their behavior; at one time they are only local, while in another, both local and systemic, as in pyogenesis, etc. These as we have seen, are mainly governed by the host's own resisting powers. Then we have many mixed processes known in bacteriology as symbiosis; as may be found with diphtheria, typhoid fever, tuberculosis, etc.

13. Progress of infection and intoxication is encouraged by negative response of the host's immunity-giving agencies. When bacteria are brought into contact with living tissues, certain wandering cells come to its rescue, devouring and peptonizing these offenders. This is the doctrine of phagocytosis, first demonstrated by Metschnikoff. Phagocytosis depends upon the character of "chemiotaxis." By this is meant the attraction ("positive chemiotaxis,") or repulsion ("negative chemiotaxis") of phagocytes. Prudden and Hodenpyl believe that the phenomenon of "chemiotaxis" is due to chemical action of bacterio-protein. The infecting agents must also meet the germicidal proteids of the blood; these may prove negative and hence conducive to the inroads of infection. Finally, when bacterial products are not rendered inert by metabolism going on within and their elimination is ineffectual, then results *progressive intoxication.*

14. The local changes resulting from bacterial action are due to the toxic "irritation which the sympathetic nerves receive and this leads to afflux of blood to the irritated part owing to the dilatation of innervated capillaries. The congestion, the stasis, the altered local diffusion and nutrient phenomena, are the natural consequences of the local irritation." Further, morphological changes will depend upon the different nature of the poisons. For instance, many bacteria form peptic

ferments which break down and dissolve the infested tissues; in other words, the tissues are converted into a condition of disintegration or necrosis of one sort or another. Then again, in some way not yet known to us, very peculiar and characteristic inflammatory changes may be brought about which result in the formation of new tissues of various kinds. As examples, we may cite tuberculosis, syphilis, etc.

15. We have seen that when pathogenic germs find a *locus minoris resistentiæ*, how they may enter the living organism and there can produce their various toxic effects. True, the chemical products have not yet all been severally isolated that must be formed in the different processes. Yet, enough work has been done in this direction, to prove that this is the right path of research to follow in pursuit of the essence of truth. But the living body is such a complicated structure of unstable component parts and functions that it is an easy matter to understand how manifold is its versatility of metabolic processes in health, how much more so in disease, *and especially so in septic diseases*. Therefore, never forget, that we have to deal with *individual*, as well as with the *materies morbi* in our diagnosis making. The symptoms of the different septic processes may manifest themselves is such a variety of perplexing ways, that it peremptorily behooves us to be on our guard. It would be a blessing if there were some unswerving pathognomonic guide to direct attention. The nearest that one may come to this is, adopt the eccentric, but never unsafe philosophy of the pangermist, to always look for sepsis. So varyingly do these different septic processes manifest themselves, therefore, always think of them. t is easy to diagnose an advanced tuberculosis, a septicæmia in the puerperal state, or a pyæmia when the local evidences are apparent; but not so, when such landmarks are not plainly manifest.

16. The bacterial poisons all more or less affect the central nervous system. This fact is variously expressed in the different septic processes. For instance, some may be especially depressing in their action upon the heart, even morphine- and veratrine-like; or they may induce atropine- and digitaline-like, and other peculiar effects resembling those of other vegetable alkaloids. Others, no doubt, have a perverting influence upon trophic nerve functions. While all of them at different times, manifest a predominant or selective action upon certain individual nerve-tracts. This may prove a source of perplexing annoyances, well calculated to over-shadow other symptoms and to mislead in diagnosis. To illustrate, let me refer to a case of pyæmia reported by me in the *Columbus Medical Journal* of March 1892, in which is shown the selective action upon the phrenic nerve. It is the case of my own brother, who for five days and five nights almost incessantly hiccoughed, sometimes from 900 to 1500 times per hour, both while awake and asleep. There was a suppuration of the left ankle, from which a metastatic pus-localization formed in the interosseous space of the left forearm, just below the elbow. The patient recovered, but very slowly and conditionally.

17. Symptoms of elimination and different types of fever often render signal service in diagnosing the different septic processes. Yet, even these may prove inconstant: e. g., who has not seen constipation in typhoid fever? or the type of this fever widely deviate from its form of continuousness, or even seen it drop by times below the normal? A combination or succession of hyperthermic and hypothermic phenomena may become manifest according to the combination or alteration of poisoning by the deleterious physiological products, or their antagonistic action. Inconstancy and fluctuation are therefore often characteristics of septic processes; especially is this true of pyæmia.

18. No doubt, explanation must be largely sought in difference of chemism. But this is yet a very hazy theme; notwithstanding the remarkably broad statement made by Dr. A. Brown, and quoted by Aitkin:—

"(1) Poisoning by the 'Extractives' is attended by hyperthermia."

"(2) Poisoning by the 'Animal Alkaloids' is accompanied by hypothermia, etc."

To this, in a letter to me, Prof. Vaughan says: "The statement is very unfortunate and is not true. The term "Extractives" is too indefinite to discuss. That "Animal Alkaloids" are characterized by the production of hypothermia is not true, is shown by a number of facts entertained in our work on Ptomaines, etc." (As

illustrations see the work of Vaughan and Novy, pages 121, 123, and 140, 141 2d Edition). However, this has no practical bearing with us. After all, we must have recourse to discrete symptomatology; it alone can guide us in each particular sep tic process. Hence, we must always carefully, but promptly consider every single diagnostic detail, since so much depends upon a *proper* and *early* diagnosis. The advancement of bacteriology and physiological chemistry, which go hand in hand, will finally triumph and do a vast deal to elucidate and eventually lead us to a correct and satisfactory conception of sepsis.

19. The treatment of septic processes may be told in one word; it is antisepsis. This means that we shall strive to over-power these pathogenic invaders. This is not so easy in practice as it would seem in theory. After pathogenic microbes have gained entrance into the body, it is more difficult to destroy them than when only in the wound. We are generally able to prevent wound diseases by an antiseptic and aseptic operation and by antiseptic dressings, since in that way we shut off the natural and only mode of entrance into the wound; but it is quite otherwise when we have once to deal with systemic infection and intoxication, as no drug has yet been suggested in any one of the septic processes, that proves at all times efficient as well as harmless, internal use of bactericide agents being very unreliable and occasionally injurious to the body. Our present knowledge of the intimate nature of sepsis and of the doctrine of immunity would seem to suggest that so far our chief reliance must depend upon cleanliness, cheerful hygienic surroundings, upon proper nutrition, to reinforce the tissues in their defensive powers; and, upon elimination, to drain the various toxines from the system through the different emunctories.

20. Hence, since within favorable environment every specific germ produces its own characteristic poison, and each poison its own characteristic effect, it is very important and desirable, that standard vitality of structure and adequacy of function, not only of larger organs, but of every solid and fluid tissue, of every individual component cell and its protoplasm be well maintained. On these conditions depends our safety; because, within them is vested the power to check invasion and the progress of micro-organisms.

SPINA BIFIDA OCCULTA.*

By A. BOWEN, M. D.,
NEBRASKA CITY, NEBRASKA.

On January 25th, 1892, I was called to J. L., a young man, who, though wasted by a month's severe sickness, gave promise by his muscular endowment, of the eulogium I had heard a farmer of my acquaintance bestow upon him, that he was the most profitable hand he had ever hired.

I found him with an irritable pulse of ninety-eight, face bedewed with perspiration and many signs of hectic fever; with great prostration, and all the symptoms justifying the prognosis of the medical man who had preceded me and who said to his mother that he would not live ten days. He was twenty-four years of age and wasted as he was, it was a laborious task for his friends to support him twenty inches above the bed, while I examined his back where all his complaint centred. I found it one vast burrowing abscess, from his shoulder-blades to his hips. It had been lanced at two points not far from the spine, without any attempt at a valvular opening, and without any regard to antisepsis. It needed but very little encouragment from a probe to evacuate from fifteen to twenty ounces of fluid, part of which was unmistakably pus, and part seemed something else, and much thinner. I found a yielding elastic, protuberance at the foramen-magnum, about the size and shape of half an egg, which his mother insisted never showed itself till after he was ten years of age. Convinced from the first that we must have more available means of suspending him above the bed for the purpose of dressing and examining his back, I bethought myself of a block and tackle, and it answered an excellent purpose for thirty-eight days. Feeling assured that the wonderfully profuse secretion from his back, jeopardized his life, I sent into every part of the abscess, by means of a small glass syringe, a four per-cent solution of carbolic acid, and as I found it immediately effective, I reduced the strength from day to day, till I was soon using only a two per-cent solution, and the secretion of pus from all the apertures did not amount to

*Read before the Nebraska State Medical Society, May 10th, 1892.

one-fourth of a teaspoonful per day, and the thinner fluid which exuded from two of what were now ulcers, at the point which had been lanced, did not amount to more than one-fourth of a teaspoonful. I was satisfied that this thinner fluid had been intended by nature for lubricating the cavity of the spinal cord. I once had borne into my hands an ordinary case of spina-bifida, in which before I left the house I had to protect the exceedingly thin membrane with a piece of oiled-silk, and as long as the child lived, there was an exudation of similar fluid. I felt under many obligations to the ladies in his neighborhood for supplying him with delicacies from their own tables, till a natural, healthy appetite rendered it unnecessary. For two months now, the patient has sat upon a chair for me to dress his back, and although I talk encouragingly to him, it seems almost impossible to cover with cuticle the ulcer from which exudes the thin fluid. He is industrious, and saws all the wood for family use. The bed-sores, (at one time very threatening) have all healed, and he seems in a fair way for perfect recovery, but I shall always give a guarded prognosis of his future. I cannot learn of any blow or strain his back has received at any time, but I learn from measurement that his left arm is a full inch smaller than his right arm, and from palpation I learn that from about his fifth cervical vertebra clear down through the dorsal and into the lumbar, I cannot distinguish any projections for any of the vertebra below the fifth cervical. He commenced complaining of severe pain about the foramen-magnum about January 1st, and the tumor at that point increased in fullness at that time, though apparently empty. I consider his ailment as a manifestation of *la grippe*. When tired, he complains of a tingling sensation in the third and fourth fingers of his left hand. I view the primary lesion of la grippe as a neurosis; followed in many instances by sequels threatening to life, through pulmonary or bronchial disease.

FOR PAINFUL GUMS IN CHILDREN.

The Paris correspondent of *Arch. of Pediat.*, mentions the following:

℞ Cocain. hydrochlorat.
Camphor. pulv ..... āā centigrammes x.
Glycerini ..... grammes x.
Essent. menthæ (to flavor) .... q. s.—M
Sig.—Rub a little of this on the gums with the finger.

WHAT'S THE MATTER?

By J. M. SHAFFER, M. D.,
KEOKUK, IOWA.

That is the all-important question which confronts the physician. The shelves of libraries are full of books which present it in one form or another. It is the foundation thought of all the multiform divisions of the art and science of medicine. What's the matter? and physiology, pathology, anatomy, chemistry and the like try to give an answer! The strong man is stricken down in field or street or shop; he lies as he fell; his pupils, skin, breathing, pulse ask you what's the matter? He is unconscious; he neither knows nor cares; and the automatic acts make the inquiry. The infant spreads its oral muscles to their utmost capacity and cries with its full volume of voice, draws up its legs and throws its arms in varied movements; tears run over the cheeks: the tongue and chin quiver and these all insist upon the question, what's the matter? The boy gets a hurt on some part in his sport, and it is of immeasurable worth to know what's the matter. A score of patients will not only tell their symptoms, but, educated in the medical almanacs and still more specious descriptions of disease in the daily press will tell what's the matter. They buy and pay for, and drink, swallow, apply and rub in dollars and dollars because they have discovered what's the matter. People feel their own pulse, examine their own tongue, go so far as to take their own temperature; estimate the significance of a pain—of a disordered sensation—of a morbid condition of the mind—and straightway determine for themselves, what's the matter and, of course, dose themselves with what some one told them was good for this thing, that thing or t'other thing. The physician's very first office is to discover what's the matter. The man who knows positively what's the matter has the advantage over the man who is merely a good guesser. Here in a given patient is an assemblage of signs and symptoms, a co-relation or an opposition chill, fever, loss of appetite headache. Bilious fever—that's what the matter. But it may be a hundred other things by name and it may not be bilious fever at all; be *certain* what's the matter. A lad meets with a tumble and hurts a

knee or hip: 9,000 other boys fell and hurt a knee or a hip; but the one boy had a pain left recurring here and there; he doesn't mind it, but after a while he walks lame. What's the matter? If not accurately determined, this one boy will go through life on crutches. And so on. What's the matter? is the one thing the physician *must* know positively clearly and be able to give a reason for his *knowledge*—absolute; not, for his opinion merely. It makes very little difference what is not done, provided it is known what's the matter. The vast majority of cases could recover without any medicine if all concerned were certain as to what's the matter and it may be that once in a century or two a man dies because the physician did not know what's the matter. It is not improbable that once in a great while a patient recovers in spite of the treatment, the doctor never being able to tell—not knowing—what's the matter.

The momentuous question at the bedside must ever be, what's the matter. A lawyer has the advantage over the physician. Ordinarily the lawyer knows little more of law than the common people, but he knows where to find it when he wants it: and can tell his client what's the matter. The physician cannot leave his patient and ransack his library: but he must *know* then and there what's the matter. If he does not know, it were well to give a placebo, that may do no harm until he ascertains certainly what's the matter. There can never be a justification for a shot at random; that is merest charlatanism. Better hesitate than prescribe a remedy unless there is unmistakable certainty as to what's the matter.

There is opportunity to score a point in telling the patient what's the matter. A lady had been bled, some drops of blood escaped into the subcutaneous cellular tissue causing a discoloration very frequent in such cases, and is of no significance. She sent for the doctor. He was a plain man, he told the patient it was caused by a few drops of blood settling in the skin; and told her to put on a wash of very weak sugar of lead water; that it would go away in a day or so, and she needn't bother about it. But he didn't tell her what's the matter.

The lady was alarmed, and wanted to know what's the matter. She sent for quite another sort of man. Oh! my dear madam, you would know what's the matter? We have here an ecchymosis.—Great Scott! you don't mean it? We will bandage it, carefully moisten the dressing with a solution of saccharum saturni, called in the Eastern Hospitals, vegeto-mineral lotion. There is no immediate danger. In a week the sanguineous effusion in the adjacent areolar tissue will be absorbed and the parts restored to their normal condition. Five dollars—thanks. She found out what's the matter.

Many cases and diseases are incurable; we must know what's the matter to satisfy the friends of the patient. Very many diseases have a determinate course; we must tell patient and nurse what's the matter, and that we can only keep away injurious influences and conduct the case to recovery. To know what's the matter is the enduring crown of glory which encircleth the brow of the well-bred, intelligent, thoughtful, Christian gentleman and physician.

GENERAL PARALYSIS OF THE INSANE IN A BOY.

Charcot and Dutil (*Arch. de Neurol.*, March, 1892) describe a case of general paralysis commencing at the age of 14 years. Up to that period the boy had exhibited nothing abnormal in his mental or physical development. Naturally vivacious and intelligent, his disposition changed at the incidence of puberty, and dementia set in; he became dull, and anergic, lost his memory, could not keep accounts. At 16 years, mental decay and arrest of somatic growth were striking; the patient's appearance was childish, evidences of pubescence were slight. There was no emotional exaltation or grandiose delusion. Tremor present in lips, tongue, and hands; anisocoria, with abolition of light reflex; articulation notably impaired, gait unsteady. Now and then an attack of "sensory epilepsy" occurred; a tingling sensation ascended from the right foot to the right half of the trunk, head, and tongue, and thence spread to the right fingers. Recurrence of so-called "congestive seizures" completed the clinical picture. Neuropathic heredity seemed to be the only recognizable ætiological factor; the patient's father was an inebriate, a first cousin was insane at periods, two grandparents died paralyzed.—*Brit. Med. Jour.*

Selected Formulæ.

AMENORRHŒA.

Prof. Lutaud, of Paris (*Manuel des Maladies des Femmes,* Paris, 1891), recommends the following formulæ in amenorrhœa:

℞ 1. Extr. nucis vomicæ.....gms. 1.50.
Ferri arseniat.....dgms. 6.5.
Mangan. sulphat. sic..... .. gms. 12.
Sufficient for one hundred pills. Three pills a day.

℞ 2. Ferr. et potass. tartrat.....gms. 5.
Extr. artemesiæ..... } āā gms 2.
Extr. absinth..... }
Aloes.....gm. 1.
Essent. anisi, q. s.
Sufficient for fifty pills. Two pills after each meal.

As an emmenagogue:

℞ 3. Pulv. indigo.....gms. 30.
Pulv. artemesiæ..... .. gms. 15.
Pulv. zinziber.
Pulv. valerian.
Use raspberry syrup sufficient to mix well; add honey as much as is desired. Two to four coffee spoonfuls two to four times a day.

In chlorotic amenorrhœa:

℞ 4. Ferr. dialyzat..... } āā gms. 50.
Aq. cinnamon..... }
A dessertspoonful two or three times a day.

THE THERAPEUTIC APPLICATIONS OF THE PHENATE OF COCAINE.

This salt is highly recommended by Von Oefele (*Revue de Therapeutique Medico-Chirurgical*, April 15, 1892) in practical medicine. The analgesic action of the new combination is said to be superior to that of cocaine by itself, while the small quantity of the alkaloid contained in it lessens the chances of producing poisonous effects, when hypodermatically administered. Here are some of the combinations recommended by the author:

(1) As a local application to the pharynx, tonsils, etc.:

℞ (*a*) Phenate of cocaine..... 1 gramme.
Absolute alcohol.....10 grammes.—M.
Sig.—Use externally.

℞ (*b*) Phenate of cocaine..... 1 gramme.
Alcoholized sulphuric ether.....10 grammes.—M.
Sig.—External use.

(2) For hypodermatic injections, and for instillations into the ear, as in the case of otalgia:

℞ Phenate of cocaine.....10 grammes.
Dissolve in alcohol..... 5 grammes.
Add distilled water..... 5 grammes.—M.
Sig.— Inject the contents of one to three Pravaz syringefuls of the solution.

(3) For spraying, or for inhalations, in affections of the larynx and bronchi:

℞ Phenate of cocaine.....10 centigrammes.
Menthol..... .....25 centigrammes.
Dilute alcohol.....10 grammes.—M.
Sig.—One fifth of this solution is used, for spraying, in the course of the day.

(4) In the treatment of acute and chronic nasal catarrh:

℞ Phenate of cocaine.....20 centigrammes.
Pulverized boric acid..... . 2 grammes.—M.
Sig.—External use.

(5) In the treatment of affections of the stomach:

℞ (*a*) Phenate of cocaine.....5 centigrammes.
Subnitrate of bismuth.....2 grammes.
Mix and divide in five *cachets.* Sig.—In cases of gastralgia, one *cachet* in the morning, before breakfast, or one hour before the expected principal crisis.

℞ (*b*) Phenate of cocaine.....7 centigrammes.
Powder of condurango..... ....1 gramme.
Mix and divide in ten small *cachets.* Sig.—In cancer of the pylorus, one *cachet* in the morning before breakfast.

—*Univ. Med. Mag.*

ACUTE ARTICULAR RHEUMATISM.

Dr. A. Hennig (*Le Bulletin Médical*, No. 44, 1892) recommends the following potion in the treatment of acute articular rheumatism:

℞ Salipyrine..... ..... 6 grammes.
Glycerine.....14 grammes.
Raspberry syrup..... 30 grammes.
Distilled water.....40 grammes.
To be taken in the course of the afternoon, a spoonful every fifteen to twenty minutes.

According to the writer, the action of salipyrine, like that of the salicylates, is especially manifest if one administer it during the afternoon, in frequently repeated doses, with a total dose of from four to six grammes. Two or three hours after the last dose the temperature falls one or two degrees and the pains become less. The patient passes a good night, and, although the temperature rises the next morning, it does not reach the height that it did before.

IN UTERINE HÆMORRHAGE.

Huchard (*Revista de Ciencias Médicas de Barcelona*, April 25, 1892) uses this prescription:

℞ Ergotine.
Sulphate of quinine, of each.....2.00 grammes.
Powder of digitalis.
Extract of hyoscyamus, of each.0 20 gramme.
M. and make twenty pills. Sig.—From five to eight pills per day.

PALATABLE CASTOR OIL.

Treat the best grade of castor oil with hot water repeatedly, then add enough saccharin to give it a syrupy taste. A minute quantity of the aldehyde of cinnamon oil and of vanilla flavoring will cover any remaining disagreeable flavor. This process is said to impair neither the efficiency nor permanence of the oil.

THE

MEDICAL and SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

DIRECT COMMUNICATIONS TO
P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor.
(Professor of Physiology, University of Penna.)

BUSINESS OFFICES:
29 to 35 North Tenth Street, Cor. Filbert.

EDITORIAL OFFICE:
Southeast Cor. 36th and Woodland Ave.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00

REMITTANCES should be made payable to THE MEDICAL AND SURGICAL REPORTER, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

—o—

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates).... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt **"The Medical and Surgical Reporter"** and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts..... $1.50 each.
Bovine Points or Quills..... 1.00 a doz.
Humanized Crusts..... 1.00 small.
Humanized Crusts..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

Leading Articles.

RECTAL GONORRHŒA.

The literature on the subject of rectal gonorrhœa is very meagre. The first mention of this variety of gonorrhœal infection we find in French writings.

In 1879, Hecker, of Paris, spoke of having observed a putrid discharge from the rectum of men and women who indulged in *coitus praeternaturalis*, which resisted all treatment. Rollet, in 1868, reported the case of a woman who in order to assist defæcation had inserted her finger into the rectum, and in this way carried the infection from the urethra, at which time she was suffering from gonorrhœa.

Rectal gonorrhœa in the male, according to the majority of French writers, occurs principally among those who submit to rectal coitus, especially boys who are used for pæderastic purposes. In the female it frequently results from self-infection, since the gonorrhœal secretion runs down between the labia, and so reaches the anal opening.

The first symptoms of rectal gonorrhœa are local itching, stinging sensations, and a feeling of uncomfortable warmth in the rectum. Later, painful defæcation and tenesmus are added. Objectively, one may find inflammation and swelling of the parts, as well as great irritability of the anal mucous membrane, and many erosions marking the parts almost like a map. This last are caused by the abundant secretions, which also cause eczema of the anal region. Examination will also usually reveal the well known signs of pæderasty.

In many cases rectal gonorrhœa can be successfully treated by suitable means, but more frequently it proves to be a most stubborn disorder, assuming a chronic form.

Our knowledge of this subject has been greatly enriched by a contribution by Dr. Franz Frisch, of Wurzburg, in the *Medi-*

cinische Neuigkeiten. Dr. Frisch gives the history of a case that will bear careful reading. The patient was a girl, seventeen years of age, a "puella publica" by occupation, who applied for treatment while suffering with urethral gonorrhœa. After a few days, she began to complain of pain in the rectum, and soon of the typical symptoms of rectal gonorrhœa as described above. The patient also confessed that she frequently had submitted to rectal coitus. The microscopical examination of the anal secretion revealed the presence of numberless gonoccoci of typical form. Their presence continued during the eight months of the patient's stay in the hospital, although the gonoccoci had disappeared from the urethra three months previously. During the patient's life a small portion of the rectal mucous membrane had been excised for the purpose of examination, but the examination was not made until after the patient's death, which occurred a year later from phthisis. The condition of the mucous membrane was found to be as follows: There was a loss of the glands of Lieberkühn, which were replaced by atypical glandular tissue, an infiltration of round cells, reaching the tunica muscularis of the rectum, and especially around the glands of Lieberkühn; there was considerable vascular engorgement, especially in the sub-mucous membrane. The polynuclear round cells were filled with the Neisser diploccocus, and the germ was in the tissues, in the lumen of the glands of of Lieberkühn, and in all parts of the tissues where a loss of substance was evident. The gonoccoci were not found to have penetrated either the muscula mucosa or submucosa, but the infiltration of the round cells reached the tunica muscularis.

In discussing these cases Dr. Frisch writes: "The demonstrated existence of ulcers and atypical glandular growths in chronic rectal gonorrhœa brings into prominence the thought that in all probability those ulcers of the rectum which are neither tubercular nor carcinomatous, rectal gonorrhœa plays a most important rôle. This is very probable when it is remembered that rectal ulcers of an uncertain origin occur almost exclusively among women, and also when the large predominence of rectal gonorrhœa among woman is taken into consideration. Finally, it should also be remembered that the most energetic local treatment with sitz-baths, irrigations with astringents and disinfectants, the insertion of cotton for the absorption of the secretion—in fact such active treatment for a period of six months as was pursued in the case alluded to, may be found wholly unavailing. Whether the use of cauterization or the curette would yield better results, practise only can answer, but it is probable since the gonoccoci only penetrate the superficial portions of the mucous membrane."

THE CONNECTION BETWEEN ARTHRITIC DIATHESIS AND TUBERCULOSIS OF THE LUNGS.

In an exhaustive article in the *Deuteches Archiv für klin Medicin*, Vol. XLVII, Dr. A. Sokolowski has dealt most ably with those forms of tuberculosis of the lungs in which various symptoms of an arthritic nature are manifested, especially renal colic, and gives some valuable points regarding the treatment of the semanifestations. He claims that in the case of a subject with extensive induration of the apex of the lung, where the general condition is excellent, and where the various manifestations of an abdominal plethora exist, that the former condition should be regarded as secondary to the latter, that the therapy should be exclusively applied to the treatment of the latter manifestations, and that these alone should receive the physician's immediate attention. Sokolowsky has found by experience, if the therapy is modified to meet the condition of the lungs, and consists in the exhibition

of slightly alkaline, or saline-alkaline mineral waters, such as Vichy or Ems, the results are by no means satisfactory; while, on the other hand, if the alkaline bitter-waters, Marienbad, or even Karlsbad, are used the results in the large majority of cases are most excellent. Of course, such a course of treatment must be undertaken with a degree of caution, and be controlled by the condition of the urine. The ground work of the further treatment should be based on dietary and hygienic principles and is as follows:

1. DIET.—The author is adverse to the view that albuminoid foods should be withheld from the patient, but accepts Thompson's opinion in that he avoids the use of either fatty or mealy substances. Alcoholic drinks should be restricted as far as possible. It is this latter form of stimulant nourishment that is always given to consumptives, and this is regarded by the author as a frequent cause of artificial diathesis. The amount of nourishment given to the patient should always be guided by the amount of physical exercise. The age of the patient must also be taken into consideration ; the older the individual the less his organism requires. Regarding the articles of diet which should be avoided by the patient the following may be included: milk, milk and water, butter, cheese, egg, cake, mealy foods, and, indeed, all dishes in the preparation of which sugar is used. The following articles, on the other hand, may be partaken of with impunity: Lean meats of various kinds, fish, game, young fowl, well-baked bread in small quantities, rye-bread similarly, vegetables both fresh and dried, but especially fresh peas, beans and the like, as well as fresh salad and asparagus. Regarding potatoes, in spite of the larger quantities of starch they contain, they may be partaken of sparingly. Among fruits, apples and any other which contain only a small amount of sugar may be eaten. Regarding fluid, all spirituous drinks, and especially beer, should be avoided, while pure cold water or slightly alkaline waters, such as seltzer, may be taken as desired, yet a moderate amount of water only should be drunk, this restriction being a most important dietary factor. Water acts as a sort of mechanical rinser of the tissues and especially of the renal canals, and by washing out the uric acid sediments it decreases both the specific gravity and the acidity of the urine.

2. Movement, or exercise, is also a most important dietary factor. The patients should whenever possible take walks in the open air for several hours every day. In bad weather, and with those patients who suffer from bronchial catarrh, suitable gymnastic exercise should be indulged in at home, and necessary apparatus for the same provided.

3. The careful maintenance of a regular action of the bowels is most important. The above diet will usually be found to keep the bowels in order, but when irregularities exist massage should be employed. and from time to time some saline aperient exhibited, bitter-water (Hunyadi) being the best for this purpose.

4. The maintenance of the proper function of the skin is also of great importance. The best means of securing this is to sponge the entire body with tepid water, followed by a brisk rubbing down with a coarse towel. Those patients who cannot endure a cold sponge bath may substitute luke-warm water, but to be followed by a brisk rubbing down sufficient to cause friction of the skin. Steam or Turkish baths are not advisable unless taken with great caution, since in consumptive subjects they are apt to cause hæmoptysis. At best they must be regarded as decidedly risky.

The results of such a hygienic and dietary course of treatment will be marked, and the arthritic manifestations renal colics, arthritic diseases of the joints, or others—will not only be

greatly relieved but may disappear entirely. Surely the method, simple as it is, is worthy of extended trial and investigation.

Book Reviews.

THE ELECTRO-THERAPEUTICS OF GYNÆCOLOGY. By August H Goelet, M. D. Fellow of the New York Academy of Medicine, and of the New York Obstetrical Society; Vice President of the American Electro-Therapeutic Association; Editor of the Archives of Gynæcology, Obstetrics and Pædiatrics. Detroit, Mich: Geo. S. Davis. Two volumes. 1892.

We heartily welcome these two volumes of the Physicians' Leisure Hour Series, in which Dr. Goelet has included the gist of the theories and treatment followed by Apostoli and his disciples, coupled with the results and suggestions of his personal experience.

The American literature on this subject, although abounding in journal articles and society reports, does not furnish any concise and complete work, and to Dr. Goelet is due the credit of amassing a great many useful facts concerning this important branch of gynæcology.

The first volume treats exclusively of electro-physics and electro-physiology, giving good descriptions of the apparatus used clinically. A number of ingenious electrodes and other instruments have been added by the author to those we already possess. The second volume deals with electro-therapeutics; and all of the various gynæcological affections in which electricity is employed are taken up seriatim.

Whatever views the reader may entertain regarding the use of electricity in certain uterine diseases, especially in fibromyomatous growths, this book impartially relates the results obtained by the author and others, and in consideration of the brief time which has elapsed since electricity was lauded by some as the remedy *par excellence* in these conditions, it may be said to be a wholly conservative statement of its real range of usefulness. Notwithstanding the modest preface by the author, this little work shows careful preparation, and will no doubt receive considerable attention from those interested in the advancement of this important field of therapeutics.

Periscope.

THERAPEUTICS.

TREATMENT FOR DANDRUFF.

The *American Soap Journal* commends the treatment suggested by Dr. Shuldhams, which is thus given in the *Lancet*:

The head should be first well washed with hot water and alcoholic soap. The latter is made from 2 ounces of pure soft (potash) soap, ½ ounce of alcohol and 10 minims of oil of lavender. After well rubbing it in the hair wash it away with plenty of hot water and thoroughly dry with a warm soft cloth. When the head is quite dry use a glycerole of tannin (10 to 30 grains to the ounce) and rub firmly into the scalp. If tannin does not seem to aid, resorcin may be used. This is to be done from one to three times a week. The following dressing may be used; Carbolic acid 20 grains, oil of cinnamon 60 grains, olive oil 2 ounces. Apply daily.

EXALGINE POISONING.

A Lockhart Gillespie (Edinburg) communicates notes of a severe case of exalgine poisoning (*Medical Press*, 1892, No. 2758). The patient, aged twenty-three years, took four doses of exalgine (methyl-acetanilide) in the course of the day (about thirty-six graines in all) for the relief of toothache.

When seen about midnight he was lying insensible, with rigid neck and retracted head, widely dilated, sluggish pupils, quiet, deep breathing, and a pulse of 79, of good tension. Soon after he became more sensible and complained of hammering inside the head. Speech was indistinct and he could not move the trunk or limbs voluntarily. Every few minutes there was a convulsion, beginning with "risus sardonicus" and groaning, followed in order by violent rolling of head and neck, spasm of cervical muscles, rigidity of both arms, and spasmodic contractions of abdominal muscles, the legs being barely affected. Tapping the head caused pain and brought on a convulsion, as did pricking the arm.

During the paroxysms the pain over the vertex was almost unbearable. At 1 A. M. ¼ gr. of morphine was injected, cold cloths applied to the head, and an hour later two purgative pills were taken. A little later he became more paralyzed and

the convulsions more frequent. Of superficial and deep reflexes the cremasteric alone could be elicited

The patient still complained of intense headache, inability to see, and total anæsthesia. As the pupils contracted the fits became less frequent. At 4.15 A. M. he was quieter; breathing central, almost Cheyne-Stokes. Pupils contracted, anæsthesia still universal. Urine presented no special features. He had a few spasms of muscles during the earlier part of the day; toward evening the anæsthesia was passing off. The excitement consequent on the visit of some friends determined a slight return of convulsions and anæsthesia during the night. The removal of the offending tooth on the following morning gave rise to a few slight convulsions, after which recovery was rapid. Temperature remained down throughout.—*Amer. Jour. Med. Sci.*

A NEW TREATMENT FOR CHLOROFORM SYNCOPE.

The method of treating cases of chloroform syncope resorted to in the clinique of Prof. Koenig, of Gottingen, is said to have given very good results, and as it is simple enough, it may be worth trying. It consists in applying manual compression over the cardiac region some thirty or forty times a minute, another assistant compressing the thorax as a whole at regular intervals in order to facilitate respiration. The compression is claimed to have for effect to empty the right ventricle, which in these cases is engorged with blood, and thus to bring about a return of the circulation. Prof. Koenig's assistant, Dr. Maas, recommends pressure more frequently repeated, and at much shorter intervals, and by this means he succeeded in reviving two patients who had shown no sign of improvement under the original plan. The operator stands to the left of the patient and presses the thumb deeply at a point midway between the apex beat and the edge of the sternum, repeating the process about 120 times a minute. Almost at once the dilated pupils contact, and the presence of an artificial carotid pulse can be felt. After a time spontaneous respiratory efforts are noticed, which are the signal for discontinuing the pressure and the artificial respiration, so long as the contraction of the pupils is maintained and the respiratory efforts do not again cease. —*Med. Press.*

CONTRARY ACTION OF CERTAIN DRUGS.

Dr. R. Lepine (*La Semaine Médicale*, 1892, No. 4, p. 21) reports an instance where ergot produced a congestion of the face. He prefers to call this an accessory action rather than, strictly speaking, a contrary one. A similar result occurred in a phthisical patient who had received one seven-and-one-half-grain dose of acetanilide, when there was marked perspiration but intense congestion of the face. This is not a paradoxical case, for, indeed, the vaso-dilators are more readily excited, and a small dose can influence these without exciting their antagonists, and in this case with diminished dose the congestion was at its height. In a case of severe acute articular and visceral rheumatism the salicylate of soda apparently caused jaundice due to congestion of the liver, and as well a rise in temperature. He believes that, exceptionally, due to particular conditions of the patient, an antipyretic may be responsible for a rise of temperature.

MEDICINE.

THOMSEN'S DISEASE IN A PARAMYOTONIC FAMILY.

Delprat publishes (*Deutsch. med. Woch.*, No. 8, 1892) two cases of congenital myotone associated with congenital para-myotone—a combination of morbid states that has not previously been described. In both the patients (brothers) the peculiar tonic spasm excited by cold, characteristic of the latter affection, developed in early childhood and involved the muscles of the face and extremities. The generation to which these patients belonged numbered 27 persons, 8 of whom were affected with paramyotone. A similar number suffered in the preceding generation, and 4 out of the 6 individuals who comprised the antecedent generation were subject to the malady. There were good reasons to conjecture that the mother of the 4 persons last mentioned was paramyotonic; assuming that she was, the heredity was continuous in certain lines of her descendants; in no other case was it atavic. The mother of Delprat's patients exhibited a severe degree of the affection before her marriage, but was comparatively free after—a fact which is noteworthy in connection with the well-known effect of pregnancy upon the general circulation. The symptoms

of Thomsen's disease appeared about the age of 15 in one of the patients, at a much earlier age in the other. Eulenburg's "myotonic reaction" was distinctly marked, but there was no tendency to closure tetanus, and a rather strong current was needed to produce minimal contraction. A persistent shortening of the digital flexors was observed; the fingers could be straightened by passive movement, but when in that position hyper-extension of the hand on wrist was impossible. The hyper-extension could only be produced when the fingers were allowed to flex.—*Brit. Med. Jour.*

PURPURA OF THE MUCOUS MEMBRANE OF THE MOUTH, PHARYNX, AND LARYNX.

Audubert (*Annales de la Policlinique de Bordeaux*, 1891, No. 5) has recorded the case of a man, fifty years old, with tuberculosis of the larynx and lungs, in the course of which purpuric spots appeared upon the uvula, the tongue, the gums, and in the larynx and pharynx, but nowhere upon the skin or in the nares. —*Wiener klin. Wochenschr.*, 1891, No. 43, p. 813.

FUNCTIONAL MITRAL DISORDER.

V. de Risi has observed in cases of chlorotic and readily-excitable girls a distinct presystolic murmur which, in a case demonstrated by Professor Senise, showed few interruptions. He formulates a hypothesis, based on an elaborate theoretical study, that the presystolic murmur can only be of mechanical origin, arising from an inorganic functional defect of the auriculo-ventricular orifice, namely, from functional stenosis. For the anatomical basis of this condition he quotes Paladino's anatomical description of the muscular fibres extending from the auricle to the ventricle. De Risi further tries to prove that the systolic heart murmurs which arise in anæmia are a result of malnutrition of the heart muscles, and that they must arise directly from disease of the muscular bands which extend from the ventricle to the valves (tensor apparatus). The disease of these bands causes an irregularity in the closure of the valves in consequence of abdominal contraction of the heart muscles.—*Centrlblt. f. klin. Med.*, No. 23, 1891.

ON PSEUDO-TABES, OR TABES PERIPHERICA.

Dr. H. Higier discusses this disease whose differential diagnosis from true locomotor-ataxia is often very difficult. It is due to a form of multiple-neuritis in which the sensory sphere is most involved. He suggests that all tabes reported recovered be treated with suspicion unless it be clearly proven that they are not cases of pseudo-tabes. The ætiology is tolerably clear. It is either toxic (lead, arsenic, alcohol, etc.) or toxæmic (diphtheria, variola, typhoid) ,or rheumatic (catching cold) in character. The ataxic walk comes on earlier in peripheral than in true tabes. In alcoholic tabes muscular atrophy begins early, as well as the electrical changes. The presence of R. D. speaks against true tabes, although the electrical condition is extremely variable in pseudo-tabes. The absence or presence of the patellar reflex is not of value in the differential diagnosis. Optic neuritis, if present, speaks strongly for a peripheral origin. The Argyle-Robertson symptom never occurs in pseudo-tabes, although opthalmoplegia does sometimes occur. The Romberg symptom occurs in both forms. The absence of vesical and rectal disturbances, of the girdle sensation, and of the gastric and laryngeal crises, all have a certain value in differential diagnosis. He then relates the histories of three cases of pseudo-tabes of rheumatic origin (catching cold), all of which showed considerable improvement under appropriate treatment.—*Deutsche Medic. Wochensch.*, No. 34, 1891.

SURGERY.

TREATMENT OF TRACHOMA.

W. F. Strangways (*Ophthalmic Record*, April, 1892) doubts the value of excision of the retrotarsal folds, through scarification of the conjunctiva, and then scrubbing it with a solution of bichloride of mercury, and other violent forms of operative procedure which have been advocated in the management of chronic trachoma. He strongly advocates the method, originally devised by Dr. Hotz, of crushing the follicles between the thumb-nails. It is very important that there should be proper exposure of the surface, and for this purpose it is advised that the

lid should be everted in the usual way; then the everted lid should be drawn upward with one thumb, while the other exercises firm backward pressure on the eye through the lower lid. The patient should be directed to look downward. As the eye is pressed backward the fold everts.—*Ther. Gaz.*

EXTIRPATION OF THE LARYNX.

The number of cases in which the operation of removal of the entire larynx has been successfully performed is gradually increasing. The latest of these was recorded by Professor Wolff at the recent session of the Surgical Congress at Berlin, where the patient was exhibited eight months after the operation. The interest of the case is enhanced by the fact that by means of an artificial larynx, invented by Professor Bruns, the patient is able to speak and sing, as illustrated before the Congress by his recitation of a monologue from Schiller's "William Tell" and his singing of "Gaudeamus igitur."—*Lancet.*

INTESTINAL OBSTRUCTION FROM GALL-STONE.

This subject has been discussed by Mr. Jonathan Hutchinson, who points out that in many cases the obstruction must come about reflexly, probably from spasm, as the size of the stone precludes the idea of a mechanical stoppage. Dr. James Israel relates a case of ileus very closely allied to Mr. Hutchinson's case. The stone removed was a small one—not more than three-quarters of an inch in the greatest diameter, so that it was impossible it would prevent the passage of gas and fluids in a distensible bowel. The patient was a lady 72 years of age, who suffered from constipation and colic of seven days' duration and severe vomiting of black material for four days, recurring every few minutes. The abdomen was soft, not actually distended, and without a trace of visible peristalsis. On laparotomy, there was found a stone in the jejunum. The intestines showed no sign of movement. The small intestine above the stone was not in the least distended; the large intestines were empty. The stone could be readily moved in either direction, so that a mechanical occlusion was out of the question. Israel hesitated at first to look upon this as the cause of trouble, and examined in vain the whole intestines. The stone was excised and the bowel opening stitched to the abdominal wound. The cessation of the dark vomit and the passage next morning of a copious stool showed that the obstruction had been removed. Unfortunately the patient died very suddenly thirty hours later of angina pectoris, from which she had previously suffered.—*Berlin. klin. Wochenschr.*, No. 1, 1892.

THE OBJECTIONS TO THE INSERTION OF DRAINAGE-TUBES INTO WOUNDS.

In the *Maryland Medical Journal* for November 14, 1891, Professor William H. Welch summed up the objections to the inserting of drainage-tubes into wounds as follows: First, they tend to remove bacteria, which may get into a wound, from the bactericidal influence of the tissues and and animal juices. Second, bacteria may travel by continuous growth or in other ways down the sides of a drainage-tube and so penetrate into a wound which they otherwise would not enter. He has repeatedly been able to demonstrate this mode of entrance of the white staphylococcus found so commonly in the epidermis. The danger of leaving any part of a drainage-tube exposed to air is too evident to require mention. Third, the changing of dressing necessitated by the presence of drainage-tubes increases in proportion to its frequency the chances of accidental infection. Fourth, the drainage-tube keeps asunder tissues which might otherwise immediately unite. Fifth, its presence as a foreign body is an irritant and increases exudation. Sixth, the withdrawal of tubes left any considerable time in wounds breaks up forming granulations and thus both prolongs the process of repair and opens the way for infection. Granulation tissue is an obstacle to the invasion of pathogenic bacteria from the surface, it has been proved by experiment. Seventh, after removal of the tube there is left a tract prone to suppurate and often slow in healing. To these Dr. Halsted adds an eighth: Tissues which have been exposed to the drainage-tube are suffering from an insult which more or less impairs their vitality and hence their ability to destroy or inhibit micro-organisms.

PROSTATECTOMY.

Dr. Tobin (*Medical Press and Circular* December 2, 1891) has successfully practiced an operation for senile prostatic enlargement, which consists in first making a suprapubic incision. A wire doubled and suitably curved is then passed through the urethra into the bladder. A straight sound arranged to receive the wire is then passed till it impinges against the urethral obstruction. The wire loop lying in the bladder is then slipped over the enlarged lobe by means of one or two fingers passed through the suprapubic opening, and while held in place traction is made until it cuts its way through, aided by the counter-pressure of the sound. The following advantages are claimed for this method:

1. As much of the gland as interferes with the escape of urine is removed and no more. 4. Such portion of it is removed in a satisfactory manner, for the wire starts from the point where the finger defines the obstruction on one side, and cuts up to the point where the instrument does so on the other. 3. A smooth surface, sloping into the urethra, is left, instead of the more or less rough one, that must result from taking away the gland piecemeal with a forceps. 4. There is very little hæmorrhage. No brilliant results are to be expected from any operation, and one should be undertaken only as a last resource. When dealing with youth we may talk of a cure; when treating the aged we may consider ourselves lucky if we succeed in making them a little better.

OBSTETRICS.

TWO EXTRAUTERINE PREGNANCIES IN THE SAME SUBJECT.

Boisleux (*Nouvelles Arch d'Obèst. et de Gynéc.*, May, 1892) observed a case where tubal pregnancy at the third month was diagnosed, and six days later there were clear symptoms of ruptured tube. An operation was immediately performed. On opening the abdominal cavity, a jet of blood gushed out: the fœtal sack was secured. Seven weeks later the patient was again found to be the subject of extrauterine pregnancy. There was a hæmatoma on the left side which rapidly grew large. A second abdominal section was performed. There were intestinal adhesions, and no pedicle could be found, as the fœtal sack was deeply situated in the left broad ligament. No ligature could be applied, but the cavity was plugged. When the bleeding was checked, a second plug was applied, and left twenty-eight hours in place, projecting above through the abdominal wound. A T-drainage-tube was inserted into the sac through the vagina. In April, 1892, the patient, aged 19, was in good health. Boisleux found chorionic villi and decidual cells in both fœtal sacs.—*Brit. Med. Jour.*

PARASITIC FŒTUS.

Leon (*Archives de Tocologie*, February, 1892) reports a curious case of double monster of the parasitic variety. The patient, a girl 3 years of age, was the daughter of native Mexican parents. She exhibited on the left gluteal region some well-marked portions of a fœtal face. These were the upper and lower eyelids of the left eye with eyelashes and eyebrows, an upper lip which perfectly covered a part of a rudimentary upper-jaw furnished with three or four well-developed incisor teeth, and a small buccal cavity with a rudimentary tongue and some fluid secretion. When the eyelids were separated a red surface analogous to the conjunctiva was exposed. Near to the groove between the buttocks was a row of silky hairs, and quite close to the base of the implantation of the upper lip was a small superficial opening. In the inferior part of the cyst the presence of fluid was detected, and on the surface of the parts were seen some mammillary projections.—*Brit. Med. Jour.*.

UNCONTROLLABLE VOMITING IN A PREGNANT WOMAN AT THE FOURTH MONTH TREATED BY SUGGESTION—CURE.

Choteau (*Archives de Tocologie et de Gynecologie*, April, 1892,) was called to see a woman living in a neighboring village suffering from repeated vomiting of pregnancy. She was 24 years old; puberty had occurred at 18; pregnant, at fourth month: she had had no previous illness. She commenced to vomit with the beginning of her pregnancy and was growing worse at this period. The vomited matter contained blood in great abundance. She was greatly

exhausted. Her skin was earthy, eyes sunken, pulse 120, temperature 38C°, urine scanty, non-albuminous. The ingestion, even the sight of a portion of food, or of a little water, would provoke painful, bloody vomiting. Nothing abnormal was found in the body of the uterus or its adnexa. The usual remedies were tried and failed. Before the adoption of extreme means, Choteau conceived the idea of employing suggestion. She was easily put to sleep by bi-ocular pressure, and the idea of cure suggested to her. She was told she could not vomit and ordered to eat and drink when she awoke.

The third day she was again made to sleep, and the idea of complete cure was suggested. From that time there was complete cessation of vomiting for fifteen days. Between the fifth month of pregnancy and labor some vomiting occurred now and then, but without gravity. The patient recovered her strength and was delivered at term of a vigorous child.—*Univ. Med. Mag.*

GYNECOLOGY.

THE ELECTRICAL TREATMENT OF ENDOMETRITIS.

Mandl and Winter (*Wiener klin Wochenschrift*, 1891, No. 52) report forty-four cases treated by intra-uterine galvanization. The anode was applied to the interior of the uterus, a current of from fifty to one hundred milliampères being used for five minutes. Two or three séances were sufficient to entirely control menorrhagia. If two periods passed without the former profuse flow the patient was regarded as cured, and was not treated further, but if no change was observed the applications were repeated several times at intervals of a few days. In cases of endometritis complicated by peri- and parametritis and disease of the adnexa the cathode was also applied for the purpose of relieving pain and causing absorption of inflammatory exudates. The tension faradic current was also found to be valuable as an analgesic. Twenty-two patients, who were under observation from three to eighteen months, were cured. In fourteen cases there was chronic disease of the adnexa and peri-uterine tissues, but recurrence of the inflammation was noted in only a single instance. The advantages claimed for the treatment are: 1. It can be safely practised at the office, an anæsthetic being unnecessary. 2. With a current of moderate strength applied for a short time the entire endometrium is cauterized to a sufficient depth to promote granulation and restoration of healthy tissue, without the cicatrization observed after the use of strong currents, or of acid escharotics.—*Amer. Jour. Med. Sci.*

PESSARY WORN THIRTEEN YEARS.

D. T. Nelson (*Amer. Jour. Obstet.*, January, 1892) exhibited last summer before the Gynæcological Society of Chicago a pessary which had been worn for thirteen years. The patient was a widow, aged 69, and the pessary had been introduced for falling of the womb. There had been a bloody discharge from the vulva for two years, during which period she had used warm water douches. For the eleven previous years she had employed nothing but ordinary soap and water for external bathing. The pessary was a "Hodge" of the open, horseshoe variety. When removed, the right-hand angle of the horseshoe was behind the sphincter of the vagina, embedded in the mucous membrane, and the right limb of the instrument presented in the vulva. The left limb was just anterior to the cervix and sunk in the mucous membrane; by pressure and ulceration it had passed through the muscular structure of the vagina, and was so firmly fixed that it could not be extracted without force. Nelson stated that he had disinfected the fœtid instrument with a preparation sold under the name of sulpho-naphthol, apparently a form of creolin, but only half the cost of the compound so called. It had completely removed the bad smell.—*Brit. Med. Jour.*

PORRO'S OPERATION FOR PELVIC CONTRACTION DUE TO OSTEO-MALACIA.

After mentioning the indications for Porro's operations Everke, of Bochum, (*Deutch. med. Woch.*, January 28th, 1892) says that osteo-malacia is the most frequent and important of such indications. He relates the following successful case. After the sixth pregnancy, five years previously, the patient had pains in her limbs and difficulty in getting about. These symptoms became worse during the seventh pregnancy, the latter half of which she had to spend in bed. The labor was tedious,

but otherwise normal. She kept her bed during the whole of the eighth pregnancy, at the end of which the pelvis presented the characteristic deformities. Porro's operation was then performed. The pains gradually diminished and in five months she could walk without assistance. In one year and a quarter she could go long distances without inconvenience. The author says that this case shows that the operation should be performed (at the time of labor), and that it is to be preferred to Cæsarean section with oöphorectomy, since (1) there is no object in leaving the uterus; (2) three wounded surfaces are left in the abdomen in the latter case, and (3) there is no fear of hæmorrhage if the uterus be removed. The question of treating the stump is then discussed, the author preferring the extraperitoneal method.—*Brit. Med. Jour.*

PEDIATRICS.

THE TREATMENT OF CHOREA IN THE HOSPITALS OF PARIS.

Marcel Beaudoin (*Revue de Therapeutique Medico-Chirurgical*, April 1, 1892), after consulting the physicians of the hospitals of Paris, publishes the different opinions expressed regarding the treatment of chorea.

In ordinary cases, See recommends antiyprin and arsenic as the best remedies. In rheumatic cases, the salicylate of sodium, according to this author, should be associated with the antipyrin and sulphur baths. In cardiac choreas, to the heart remedies should be added the administration of iodide of potassium, and especially the iodide of calcium.

Gilbert Ballet believes that common chorea tends to a spontaneous cure, and that, therefore, all disturbing medication should be withheld. He condemns antipyrin, but recommends arsenic (Fowler's solution in small doses, that is, from six to twelve drops a day, according to the age of the patient), tonics and iron in anæmic cases. In serious cases he advocates the local application of ether to the vertebral column, and the bromides in patients laboring under psychical troubles. Above all, the author advises hygiene, a good alimentation, and walking in the open air, avoiding fatigue.

According to Dejerine all special medication in infantile chorea is useless. He recommends tonics, massage, gymnastic exercises, dry frictions, salt-baths, and particularly insists on the application of good hygienic measures.

In mild cases, Joffroy attaches particular importance to allowing children to sleep as long as possible: in such instances he is wont to employ daily doses of from 1 to 1.75 grammes of chloral, according to the age of the patient. Fatigue, as well as all physical and mental excitement, should be avoided. In serious cases he believes that antipyrin is useless, and he then resorts to the application twice a day of wet cloths.

Antipyrin has given the best results in the hands of Albert Robin. He combines this drug with bicarbonate of sodium, and gives it in as high a dose as two grammes a day. After fifteen days' use the antipyrin is substituted by the arseniate of sodium in doses of two teaspoonfuls a day, of a solution of five centigrammes to 300 grammes of water. This solution finished, is followed by the re-administration of the antipyrin.

Raymond thinks that only two remedies are to be relied upon in the treatment of chorea; chloral and antipyrin; he has seen acetanilid do good in some cases.

Sevestre believes in the use of both antipyrin and arsenic. The first medicament is administered in doses of from one to two grammes, and even three and four grammes a day. He employs, at the same time, Fowler's solution in daily amounts of from six to twelve drops, or a solution of the arseniate of sodium (five centigrammes in 250 grammes of water) in doses of two to three dessertspoonfuls a day.

Massage, according to Ollivier, has given satisfaction in the treatment of choreic patients. This author also prescribes, as a general medication, iron, arsenic and hydrotherapy.

D'Heilly recommends hygienic measures, tonics and prolonged sleep. In slight cases he thinks that such remedies as arsenic, iron, bitters and baths are sufficient. In more serious cases he resorts to antipyrin and chloral as the best drugs.

Antipyrin is likewise highly recommended by Legroux in doses of four grammes per day. In hysterical cases the bromides and cold douches have given him the best results.

Comby insists on the application, *firstly*, of a moral and physical hygiene; *secondly*, in the sedation of the system by bromide of potassium, in daily doses of from two to four grammes, and the use of cold douches. If no amelioration follows this treatment, antipyrin, in daily amounts of from two to three grammes, should be resorted to.

Jules Simon gives the following points: (1) During the first fifteen days the child is to lie in bed, and revulsion applied over the upper part of the back, by warm frictions, mustard plasters or dry cupping, and the use of aconite and hemlock. (2) After this time, the child is made to get up, and then antipyrin should be administered in progressive doses of one, two, three, four and five grammes in the course of the twenty-four hours; this medicament to be continued for several weeks. (3) This period, especially when the movements are sluggish, should be followed by rhythmical gymnastics. The same author prescribes, at the same time, the least exciting tonics, auch as salt-baths, dry frictions, etc.; but a stay at the seaside is condemned.—*Univ. Med. Mag.*

HYGIENE.

HOW LONG SHOULD A CONVALESCENT FROM DIPHTHERIA BE ISOLATED?

Prince (*Boston M. and S. Journ.*, 1891, cxxv., 691.) writes of a case, the patient was supposed to be well, and made a visit to a relative in Boston nine days from the date of his "getting up." One week after his arrival a child in the family was attacked with diphtheria and died. An outbreak of diphtheria in a hotel at Nantucket followed the arrival of a person just recovered from diphtheria and pronounced well by the attending physician. One of these cases, when supposed to be well, carried it to a hotel in town. Three cases of diphtheria in one family, closely followed the advent of a nurse who had just come from attendance on a fatal case.

I think that evidence goes to show that poison is retained in the mucous membrane longer than is generally considered to be the case. In lieu of definite knowledge I have adopted the arbitrary rule of advising quarantine precautions for one week after the patient appears to be perfectly free from disease. This seems to be a fairly safe rule and one that is desirable.

EXPERIMENTAL RESEARCHES ON THE TRANSMISSION OF CANCER.

After a series of experiments on various animals Duplay(*Gazette des Hopitaux*,No. 23.), draws the following conclusions:—(1) Cancerous neoplasms are not transmissible from man to animals; (2) contrary to what was expected from the results of other experimenters, only negative results were obtained as to the transmission of cancer from one animal to another of the same species, after a lapse of time varying from three to eight months; still until more experiments have been made, and under more favorable conditions,no definite conclusion is arrived at; (3) cancer is not transmissible from one animal to another of a different species; (4) the results do not permit the denial of its parasitic nature, whilst at the same time they do not enable the author to affirm it. This question remains, then, undecided.

A NEW METHOD FOR THE DETECTION OF TUBERCLE BACILLI IN MILK.

Ilkewitch (*Muncher medicinische Wochenschrift*, February 2, 1892) describes a new method for the detection of tubercle bacilli in milk, which is founded on the fact that tubercle bacilli will be precipitated by rapid centrifugal motion. He uses a modified lactocrit, which has 3,600 revolutions a minute. Twenty ccm.of milk are coagulated by means of dilute citric acid, The whey is separated by filtration. The casein is dissolved with phosphate of soda solution. To this are added six ccm. of sulphuric ether, mixed with water, in order that the emulsified fat corpuscles may be set free. The action of the ether is hastened by shaking the mixture in a glass cylinder for fifteen minutes. The solution is allowed to stand, and after the fat has separated, the remainder of the liquid is allowed to run out. Dilute acetic acid is added to this until the first sign of coagulation. It is then transferred to the lactocrit, and the machine set in motion for fifteen minutes. The vast majority of the bacilli then sink to the bottom. This deposit is then conveyed to two slides, stained and examined with an oil immersion. If bacilli were present in the milk they will be found almost surely in this precipitate. The author considers this method more certain than the inoculation of animals with the suspected milk.—*Univ. Med. Mag.*

MEDICAL CHEMISTRY.

LÉVOISNE.

M. Tanret (*Rèpertoire de Pharmacie*, No. 8) has succeeded in isolating a new hydro-carbon, lèvoisne, from cereals. He experimented successfully on rye, barley, and oats. To "lèvoisne" M. Tanret has given the formula C_{48} H_{40} O_{40}, the same formula as amidon and dextrine. It turns the plane of polarized light to the left, hence the name; it is of a white color, amorphous, insipid, soluble in water, very soluble in dilute alcohol, sparingly so in the strong liquid. It does not reduce copper and is not affected by alkaline solutions.

ESTIMATION OF SMALL QUANTITIES OF STRYCHNINE.

At a meeting of the Chemists' Assistants' Association, held at London on March 17th, Mr. R. H. Davies presented a modification of the old method of testing for strychnine with potassium bichromate and sulphuric acid, which had been first worked some years previously by the lecturer, in conjunction with Mr. Oscar Echenstein, for estimating minute quantities of strychnine. Mr. Davies described the usual method of applying the test on a white slab, treating the bichromate and strychnine separately with sulphuric acid, and then drawing the two together, when the characteristic play of colors is produced. A more efficient method, as he demonstarted, is to make a very dilute solution of potassium bichromate in strong sulphuric acid, and then add the strychnine in solution to this in a test tube, when the reaction can be easily observed. The first colors produced soon disappear, giving place to a reddish-orange which is fairly persistent; and it was by means of this color they endeavored to estimate the quantity of strychnine under examination by a process similar to Nesslerizing. Mr. Davies showed a series of these tests, comprising the plain solution of bichromate in strong sulphuric acid, and similar quantities of the solution with $\frac{1}{2500}$, $\frac{1}{1000}$, and $\frac{1}{500}$ gr. of strychnine added. A very distinct difference between them was observable, and it was evident that it was quite practicable, by comparing with a solution of strychnine of known strength, to get an approximate idea of the amount of the alkaloid present.—After *Chem. and Drugg.*

DOCTORS OF PHARMACY.

The University of Munich has created a new degree—Doctor of Pharmacy—which will be granted after a course of seven semesters and examination in one principal subject, chemistry or botany, and in three secondary subjects, namely: mineralogy, physics, and zoology. An inaugural dissertation must also be presented.

RECTAL MUSIC.

The members of the Surgical Congress which has just risen at Paris were invited to witness the performances of a "physiological curiosity," in the person of a man who rejoices in the ability to aspirate large quantities of air or water *per rectum.* Seated in a hip-bath he can by a voluntary effort draw two or three quarts of water into the large intestine, and some idea of the muscular strength called into play is afforded by the fact that this fluid can be ejected to a distance of from five to seven yards as the crow flies. A close examination of the "subject" showed that the aspiration is performed in the following way:—The diaphragm being fixed by a deep inspiration, the glottis is closed, and all the extraordinary muscles are called into play. This produces a dilatation of the lower part of the thorax. At this moment the epigastric region yields to the pressure of the external air and becomes markedly concave, the iliac fossæ following suit. The condition of negative pressure thus created causes an inrush of air through the anus, the aspiratory effect being carried a step further by the action of the diaphragm on the lower ribs, which are pulled upwards and outwards. The man first discovered his peculiar talent when a lad, his attention having been called to it by the involuntary passage into the intestines of large quantities of seawater when bathing. Since then he has cultivated it, and for some years past has made—not exactly a decent, but an ample livelihood, by rendering musical airs at various places of public amusement in the Modern Babylon. To the astonishment of the surgeons he imitated a number of musical instruments—the trombone, the human bass voice (non-articulate) the violin, &c., and with sufficient talent and accuracy to render the selection of airs perfectly recognizable.—*Med. Press.*

CH. MARCHAND'S

PEROXIDE OF HYDROGEN.

(MEDICINAL) H_2O_2 (ABSOLUTELY HARMLESS.)

THE MOST POWERFUL BACTERICIDE AND PUS DESTROYER.
ENDORSED BY THE MEDICAL PROFESSION.
UNIFORM IN STRENGTH, PURITY, STABILITY.
RETAINS GERMICIDAL POWER FOR ANY LENGTH OF TIME.
TAKEN INTERNALLY OR APPLIED EXTERNALLY WITH PERFECT SAFETY.

Send for free book of 72 pages giving articles by the following contributors:

DR. JOHN V. SHOEMAKER, of Philadelphia, Pa. Professor of Materia Medica in the Medico-Chirurgical College of Philadelphia. "Peroxide of Hydrogen." *Materia Medica and Therapeutics, with especial reference to the Clinical Application of Drugs.* Vol. II., page 681.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{30}$ gr.), Atropiæ Sulph. ($\frac{1}{300}$ gr.), Codeia ($\frac{1}{30}$ gr.), Antimony Tart. $\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{60}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonial from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of th profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that th applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

38 Maiden Lane, **New York City.**

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL AND NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

Clinical Lectures.

CLINICAL REPORT OF CYSTECTOMY FOR POLYCYSTIC OVARIAN TUMOR.

By PROF. HOWARD A. KELLY,
AT THE JOHNS HOPKINS HOSPITAL.

(Reported by J. G. Wiltshire, M. D., of Baltimore.)

Gentlemen:—I bring before the clinic for examination to-day the case of Miss A., white, aged 21, single. She menstruated first at seventeen and was always regular in her habit, having a moderate flow lasting four days with but little pain up to her last period, Sept. 1st, 1891. Since then in place of menstruation, she has had a somewhat offensive leucorrhœa. She has been sent to me for treatment by Dr. S. Birnie, of Taneytown, Pa., and Dr. Simpson, of Harney, Md. About Jan. 1st, 1892, two months ago, her physicians had their attention called to a supposed tumor in her left iliac region, although she had noticed some enlargement in November. The abdomen grew rapidly, with sharp pains at first, until it attained its present large proportions. She says that she was feverish at first as it was growing; emaciation of the body kept pace in inverse proportion with this growth of the tumor and the increasing girth of the abdomen.

She now comes before you for a critical examination under ether. The note tells us further that her bowels are regular and there is no urinary trouble. She has never had any serious illness, and her family history is negative. Upon making a general inspection you will observe at once that her face is anæmic, thin, haggard, and drawn, bearing evidences of profound nutritive disturbance, there is also a peculiar pallor of a greenish yellow cast—a species of cachexia, suggestive at first sight of malignant disease lurking in some part of the body. Her expression, however, is more that which has been termed *facies ovariana*, the emaciation indicative of advanced ovarian disease. The pulse is slow and feeble. The respiration as you see is superior-costal, owing to the compression made upon the alate lower chest by the swelled abdomen.

Closer examination reveals no disease of the chest. There is no œdema anywhere.

Upon inspecting the abdomen, we find it greatly distended, ovoid in form, remarkably smooth on its surface, somewhat larger on the left than on the right side. The umbilicus is pressed out even with the surface, and is distant 21 cm. from the symphysis, and the same from the ensiform cartilage. When there is much free fluid in an abdomen as large as this the umbilicus is prone to be elevated much above the surface forming a slight hernia. We thus record in passing, a point against this tumor being an ascitic accumulation.

Observe closely and you will catch sight of a peculiar little wave constantly playing over the surface; this is not respiratory, it is cardiac in its rhythm, aortic in time; it is an important sign tending to show that something more or less tense or solid rests directly upon the aorta, filling up the space between the aorta and the anterior abdominal wall, for only in this way could the aortic pulsation be so clearly transmitted. It is really a percussion wave from behind. This also tends to demonstrate that the enlargement in our patient is not free fluid, but is either solid or enclosed in a tense sac.

Percussion reveals a corona of high pitched resonance over the upper surface of the tumor which I thus outline with an aniline pencil. The line thus made you

see is curved, lying just below and parallel to the ribs, with its convexity turned up, and its concavity looking towards the symphysis pubis. I first introduced this graphic method of demonstrating and studying various intra-abdominal and intra-thoracic diseases ten years ago when a resident at the Episcopal Hospital, Philadelphia, and have found it of great value, particularly when left on four or five days, in mapping out effusions or swellings which may change their outline from day to day. As I now proceed to percuss over the tumor (?) and on all sides, you note that while the vaulted prominence itself is absolutely flat, it is surrounded on three sides, the upper and the two lateral, above and in both groins, by a peculiar tympanitic note belonging to the colon. The whole inferior zone however on the pelvic side, is again absolutely flat.

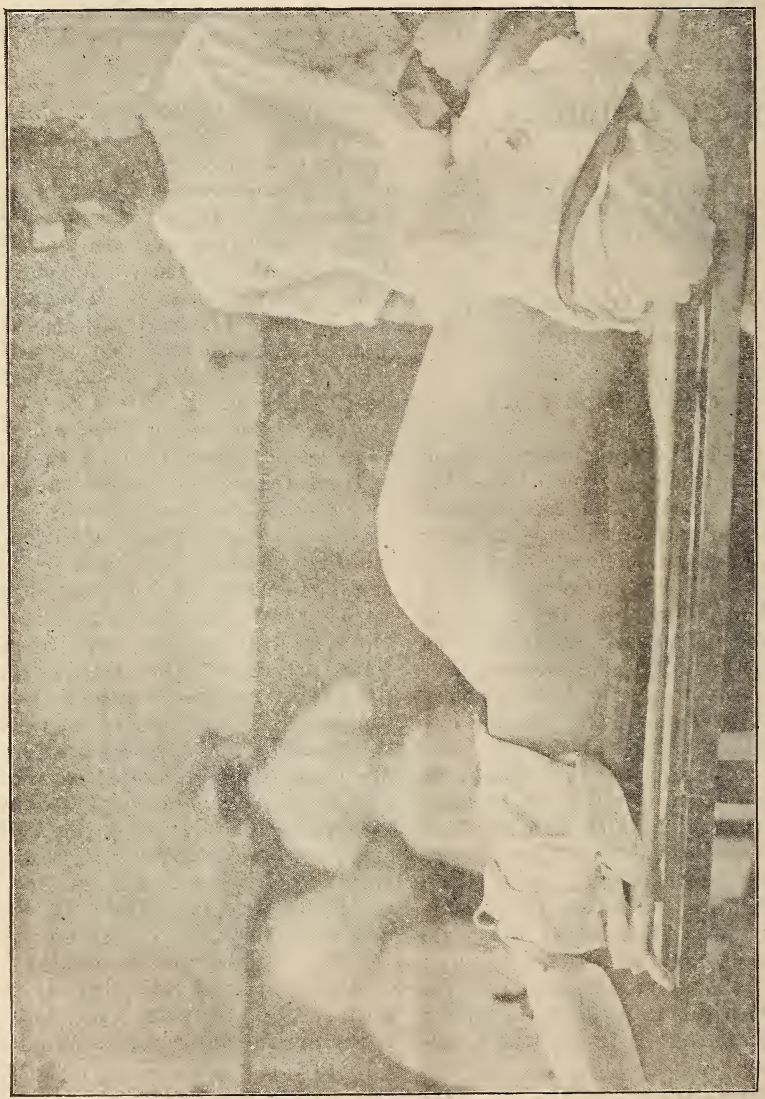

Fig. 1.—Patient on the operating table. A side view of a smaller ovarian cyst, weighing twelve or fifteen pounds, showing its characteristic contour, not unlike that of a uterus in the seventh or eighth month of pregnancy.

This peculiar circumscription in an area of dullness, having its base or point of origin as it were below, indicates a more or less coherent foreign mass in the abdominal cavity; the continuance of the dull percussion note downwards without the intervention of any area of tympany as

above, indicates an organic connection with the pelvic organs and at once suggests the pelvic origin of a tumor.

Aside from this direct evidence that we are thus dealing with a pelvic tumor, we we will make our demonstration clearer if we also seek evidence by exclusion, that is by percussing out the various important solid viscera, when if we find them all "at home" so to speak, we will feel more than ever assured as to the pelvic origin of our tumor.

You now note above the tympanitic zone, in the median line my strokes demonstrate an area of peculiar tympanitic dullness. What can it be? By continuing the percussion over towards the right hypochondrium you observe that this note gradually shades off step by step by the finest gradations of sound into the absolute dullness of the liver, showing by this continuity that the "tympanitic dull" area marks the location of the left lobe of the liver.

The spleen also is easily demonstrated near its normal site, and the tympanitic flanks exclude the kidneys from participation in the disease.

We thus again by exclusion reach the

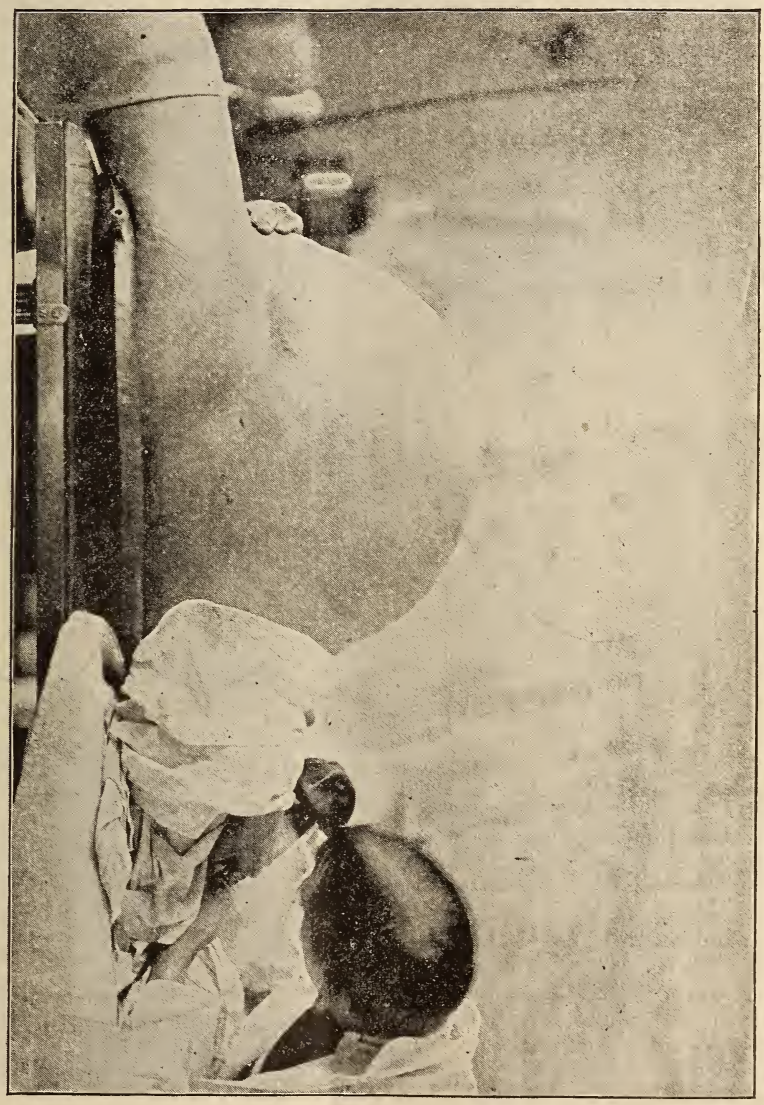

Fig. 2.—The photographic side view of a similar large ovarian cyst, showing the marked spherical distension of the abdomen due to the presence of a large sac distended with fluid.

conclusion that this is a pelvic tumor and the area of resonance surrounding it is the *corona uterina* or *ovariana* characteristic of a uterine or ovarian tumor.

Palpation shows that we are dealing with a homogeneous fluctuating mass, with no bosses or irregularities on its abdominal surface.

Per vaginam: The vagina is lax and the small cervix depressed towards the pelvic floor; the pelvis is distended with an elastic cyst filling the retro-uterine pouch, fuller on the right side. The pelvic organs are thus displaced downwards on the floor by

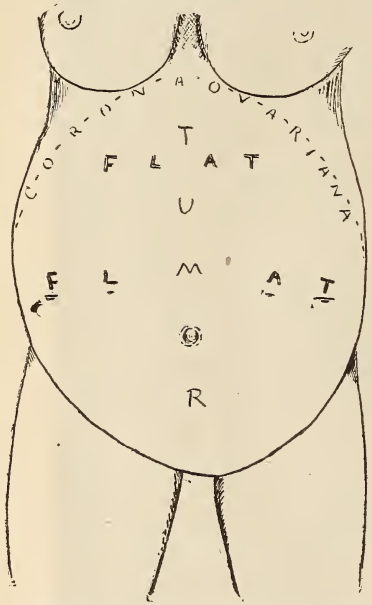

Fig. 3. The distended ovoid belly of the patient. The tumor occupies about all the small circular area outlined. Above is the *corona ovariana*, here the tympanitic note of the displaced intestines appears distinctly on percussion. The areas marked "Flat" occupy the whole of the abdomen below the *corona*, and demonstrate the presence of the large tumor immediately beneath the abdominal walls.

the superincumbent weight of the tumor. The body of the uterus is anteflexed and tilted over into the left flank, and rests upon Poupart's ligament. I feel also a small boss posteriorly which may be a displaced ovary.

Per rectum: Palpation by this avenue further confirms the diagnosis which is forming as to the character of the tumor.

We have to deal with a cystic, ovarian tumor, of rapid growth probably of an adenoid or papillary nature. Its point of departure is from the left broad ligament as shown by the fact that the uterus is drawn over to the left side. In small tumors a reverse displacement is the rule. This appears also to be either a mono-

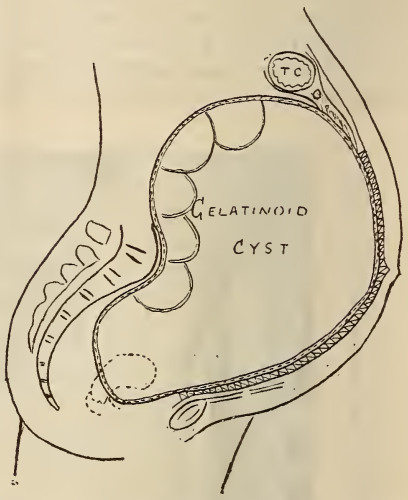

Fig. 4.—A sagittal section through the tumor described in the paper. "T. C." is the transverse colon above, immediately below this "o" the omentum, is intimately adherent to the cyst wall. From the omentum down to the symphysis the cyst is seen to be adherent to the anterior abdominal wall. In the posterior part of the cyst are seen a number of small daughter cysts. The uterus is seen outlined low down in the pelvis and anteflexed.

cystic tumor or a tumor with one large and a number of smaller cysts.

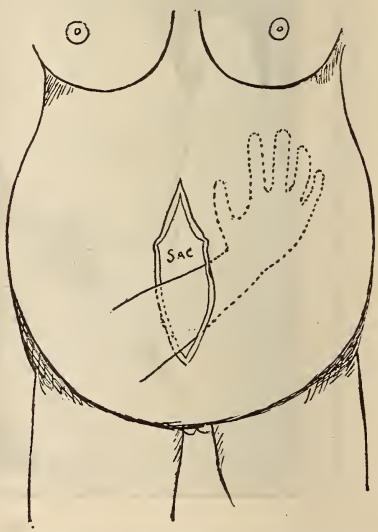

Fig. 5.—The incision extending through the umbilicus. The sac is seen through the gaping edges of the incision. The right hand of the operator is introduced between the sac wall and the parietal peritoneum, by opening and closing the fingers and pushing the hand along the tumor is being stripped loose from its adhesions.

Monocysts in general are of two kinds, *ovarian* and *parovarian*. The latter of

slower growth, contain a limpid fluid and if tapped or accidentally ruptured the fluid sometimes does not re-accumulate, in this simple way establishing a cure.

nature by the general effect on the nutrition as well as by an overgrowth on the surrounding tissues. Their rapid growth is often accompanied by a most marked

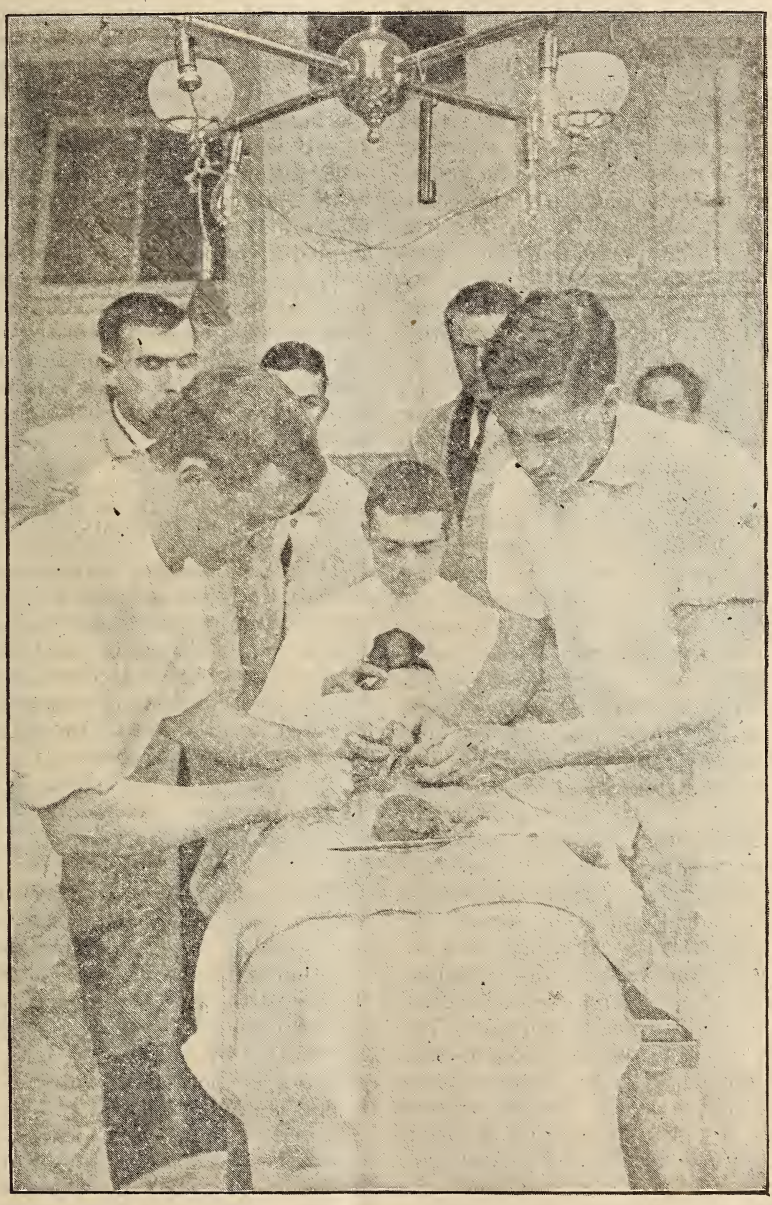

Fig. 6.—Grouping at an operation. The operator, his chief assistant, the anæsthetizer, and some visitors grouped about the operating table. A small ovarian tumor is being lifted out of the abdominal incision, which the assistant is holding open with a retractor, while the operator is engaged in transfixing the pedicle preparatory to ligation and removal.

The ovarian cases spring from the base or stroma of the ovary, and often contain adenoid and papillary masses, growing rapidly and evincing their malignant cachexia. This may be a tumor of this class.

Nothing, however, but the operation itself—cœliotomy—can settle this finer

question positively, to the advantage or disadvantage of the patient.

Operation, Monday, February 29th, 1892, under ether anæsthesia. The bowels had been regulated, the diet restricted, and the urine carefully examined, and the abdomen prepared by daily washings in the ward. It was again, however, thoroughly cleaned on the operating table with soap and water, ether and alcohol. The field of operation was then covered with a wide piece of aseptic gauze, and sterilized towels laid above and below the chest and thighs. A slit in the gauze exposed that portion of the abdomen which was to be opened for the removal of the tumor. An incision 10 cm. in length [4 in.] was made in the median line below the umbilicus, disclosing at once the glistening wall of a large ovarian tumor. On attempting to tap the tumor no fluid flowed. The cyst was filled with a tenacious gelatinoid mass. It was therefore necessary to enlarge the incision until it extended above the umbilicus. The wall of the tumor being everywhere adherent to the abdominal wall, these adhesions were rapidly broken up by passing the hand in between the cyst and the abdominal wall, using the fingers with a shearing movement. A large part of the omentum which was closely adherent to the tumor was removed and its vessels controlled by six ligatures. The tumor was then lifted out of the abdomen *en masse*. Its pedicle sprung from the left side where it was very broad, requiring eight ligatures to tie it off.

The abdomen was thoroughly washed out with 4 litres [4 quarts] of normal salt solution. An actively bleeding area on the anterior abdominal wall was controlled by a circular suture introduced all around the margin and drawn tight and tied. The right ovary and tube were free from disease.

After removing all water from the abdomen the incision was closed without drainage. A continuous suture of catgut was used to unite the divided peritoneum, and silk-worm gut to bring together the skin, muscles and fascia. The duration of the operation was a half hour.

Convalescence was rapid and satisfactory. The temperature went up to 100½° on the second day, and varied from 98° to 100° up to the tenth day. The pulse after the first day ranged between 84 and 96, but with an elevation of temperature to 101° on the tenth day due to suppuration in the incision the pulse also went up to 112.

A slight stitch-hole abscess was noticed on the seventh day, from this pure cultures of staphylococcus aureus were obtained.

On the twentieth day a marked induration was noticed around the lower part of the wound, followed immediately by a free discharge of pus. This was entirely healed in six days.

A letter from her physician received more than two months after the operation states that she is perfectly well, and occupied in doing light house work.

[I have felt an interest in reporting this case, as exhibiting the simple and satisfactory technique of these operations at the Johns Hopkins Hospital, the operation being one of a long series I have witnessed there from week to week for two years past.—J. G. W.]

CINNAMIC ACID IN SURGICAL TUBERCULOSIS.

Dr. A. Landerer has employed this remedy in 45 cases, of which 31 were cured, 7 improved, 1 unrelieved, 2 died, and 4 were still under treatment at the time of the report. In cases of tubercular arthritis an emulsion of cinnamic acid was injected into the joints, the following formula being employed:

℞ Acid cinnamic.....5.0
Ol. amygdal.....10.0
Vitelli ovi unius
Sol. sodii chlorid (0.7 per cent.).....
q. s. ut fiat emulsio.....100.0

The cinnamic acid is first rubbed fine with the oil, then the fresh yolk of one egg is added, after these have been mixed together the salt solution is added in drops. The resulting emulsion has a strongly acid reaction, which before it is used must be neutralized by addition of a 25 per cent. solution of potassium hydrate. About 5 c. cm. is deeply injected and the injection repeated twice a week. In cases of fistulous processess a solution of cinnamic acid in alcohol (1 to 20) was injected into the surrounding tissue. If this was insufficient the foci were laid bare, curetted and tamponed with balsam of Peru gauze, or cauterized with cinnamic acid in alcohol. Frequent irrigation of wound cavities with the latter or with Peru balsam was also found of value.—*Wein. Medizin Presse*, No. 11, 1892.

SURGERY OF THE GALL-PASSAGES AND LIVER.

By DR. W. KÖRTE,
BERLIN.

(*Continued from the last issue of the* REPORTER.)

Cholecystotomy with subsequent suture or cholecystendysis, as it has been called by Courvoisier, the father of the operation, has usually been designated as "ideal" but "dangerous." The danger feared was the possible bursting of the suture, but numerous cases have shown that this danger does not exist, that is when suitable cases for the performance of the suture have been chosen. The choledochus must be free and the walls of the gall-bladder strong. For this reason also, I have hesitated in performing the suture in cases of empyæma of the gall-bladder. According to Voight's report in the *Deutsche Medicinische Wochenschrift,* Heusner has made his suture in thirteen cases with entirely satisfactory results.

The great advantage of the operation lies in the fact that by means of it a more rapid complete healing—and therefore cure—can be obtained than by any other method, since biliary fistulæ, which are so unpleasant, are avoided thereby. Apart from the great discomfort caused to the patient by the constant discharge of bile from these fistulæ, the loss of bile entailed is by no means an immaterial one. In some cases that have come under my notice from 300 to 700 grammes of the fluid have been absorbed by the dressings. It seems that some persons bear well the loss of bile, while it affects others most unfavorably. These latter patients will become greatly emaciated in spite of the maintenance of a rich, nourishing diet.

An advantage of the gall-bladder suture, besides that of doing away with the possibility of fistula, is the fact that the abdominal wound may at once be closed, all but a small opening for the strip of iodoform gauze. In this way the ultimate probabilities of abdominal hernia are not nearly so great as when the gall-bladder is stitched to the abdominal wall. Again, when the incision is made parallel to the edge of the ribs, the possibilities of subsequent hernia are materially lessened in my estimation. The scar is close to the thorax and the liver lies behind it, and in this way the intestines do not exert any material pressure upon the scar tissue. Moreover, in women the corset acts as a compressing bandage and removes the pressure upon the wound.

In the majority of cases of simple concremental formations in the gall-bladder, and of occlusion of the ductus cysticus by stones, with subsequent dropsy of the gall-bladder, I consider cholecystotomy with subsequent suture and replacing of the gall-bladder as the best procedure. In such cases I would never contemplate the extirpation of the gall-bladder, although the procedure may be attended by good results when performed skillfully—this fact is demonstrated by Langenbuch's results. Nevertheless, I do not consider Langenbuch's reasons for the performance of the operation as well founded. In four autopsies performed in cases of gall-stone I have found small concremental formations in the liver itself, while Langenbuch boldly asserts that these stones can only be formed within the gall-bladder, and that the removal of the latter removes also their source of formation. My own experiences are however, also upheld by such authorities as Weigert, Sendler, Thornton, and Courvoisier, and possibly also by Braun and Buchanan, who have also found concremental formations in the liver itself.

If after the operation of cholecystotomy concremental formations again subsequently make their appearance in the gall-bladder, a second operation would be accompanied by no greater difficulties than the first, similarly as in a relapse in cases of stone in the bladder. This possibility of a recurrence of the trouble, would not, however, offer any inducement to me regarding the advisability of an extirpation of the gall-bladder. It seems also to me to be an unspoken law of conservative medicine—or rather surgery—that an organ which can be retained with justice should not be removed—and the utility of the gall-bladder cannot be denied. Finally, I must not forget to add, that the extirpation of the gall-bladder is an operation of far greater technical difficulties than its opening and subsequent suture. I would reserve the operation of cholecystotomy for performance only in such cases in which the walls of the gall-bladder are of such a nature as not to warrant the immediate suture.

In five cases of dropsy of the gall-bladder (hydrops) (Cases I to V) stones were found ranging in size from that of a pigeon's egg to the size of a cherry. Usually several stones were found in each case, and in one case several small ones as well (Case V). In Case IV, a stone as large as a pigeon's egg was found that closed the cystic duct. Out of the six patients operated upon for enlargement of the gall-bladder, in only one were no stones found. This patient (Case VI) was sent to me by her physician, Dr. Walsten, having been suffering for nine months with the most severe vomiting of all foods, as well as cardialgia. The gall-bladder was enlarged and easily felt, and yet when I opened it I only found a large quantity of gall, but no stone; neither could any concremental formations be found in the bile ducts. The pylorus and stomach were found normal. The liver, however, did not appear entirely normal. After the gall-bladder was closed it was fastened to the peritoneum at the edge of the ribs with a few buried sutures. The condition of the patient improved wonderfully. She had no pain and could eat heartily. After her return home, however, the old symptoms gradually returned.

In one case, my diagnosis wavered between that of gall-stone and of a malignant growth of the liver. An exploratory incision was made and a carcinoma of the liver found (Case VII).

In the four cases of empyæma of the gall-bladder, serious conditions were present in all. In the least serious case the gall-bladder had grown fast to the abdominal wall, and the suppuration had extended into the latter (Case VIII). In this case there was no stone and the cystic duct was obliterated. Another patient besides suffering both from suppuration and stone in the gall-bladder, had consecutive suppuration of the gall-ducts in the liver, and carcinoma of the pancreas as well. It is almost needless to say that this case had a lethal ending. In the third case suppuration in the liver and in the subphrenic space occurred as consequent to the empyæma of the gall-bladder. After many operations these various foci of suppura- were found and successfully treated (Case IX), finally an occlusion, of the choledochus also occurred, and this was also successfully treated. The fourth patient (Case X) applied for treatment when already suffering from symptoms of septic poisoning. At the operation the outer surface of the gall-bladder was seen to be discolored being yellow in portions. Three large die shaped stones were removed, the mucous membrane was found to be partly necrotic. It will be seen that the patient was operated upon just in the nick of time to save her from complications which soon must have terminated fatally, or at least as soon as the suppuration extended to the abdominal cavity. Even after the operation there were very threatening symptoms which pointed towards suppuration of the liver, but these fortunately abated after a time. The necrotic parts of the mucous membrane of the gall-bladder sloughed off. From the pus found in the gall-bladder, pure cultures of the *bacterium coli commune* were found—this is as Naunyn has also observed.

In all cases, empyæma of the gall-bladder proved itself to be a most dangerous disease, accompanied by most grave effects. The operation consisted in an opening of the gall-bladder and stitching it fast to the abdominal wall. In two cases the gall-bladder had already formed adhesions to the abdominal wall, prior to the operation in consequence of the inflammatory process. In these cases the operation was, therefore, considerably simplified.

The severest symptoms manifested by any disease of the gall-duct system, were seen in cases of occlusion of common gall-ducts. This is usually occasioned by stone, but less frequently by the formation of cicatrices, or by tumors that exert a pressure from without the gall-bladder. The great dangers of this condition are very palpable and well-known. The secretion from the liver is prevented from entering the digestive system, on the one hand, and the bile is forced in the circulation, giving rise to cholæmia. The fact that we can relieve this conditiou by the use of the knife, can rightfully be regarded as a triumph of surgery. It has been the ingenius propositions of von Winiwarter that first shed light upon this important subject. He taught that if a communication were re-established between the gall-bladder and the intestine, that the gall would again be absorbed by the digestive system. In other words, he was the first both to suggest and perform the operation of cholecystoënterotomy. His successful operations have been repeated also by other

surgeons.* In connection with Winiwarter's operation Sprengel also succeeded in establishing an anastomosis between the enlarged ductus choledochus and duodenum.† While this operation gets around the occlusion of the gall-duct by the creation of a connection with the intestine it also acts directly upon the occlusion by stone, of the choledochus. The stone has been crushed in the gall-passage and débris pushed into the intestine (Langenbuch, Kocher, Credé) and finally the stone has been cut out of the exposed ductus choleodochus and the wound sewed up (Heusner, Küster, Courvoisier) and with good results.

Frankly, those operative methods which deal directly with the cause of the occlusion —the gall-stones—are preferable in such cases in which a removable of the occlusive cause is of principal importance. If the occlusion be caused either by cicatrices or tumor, the creation of a gallic-intestinal fistula is the only rational procedure; this is equally true when sufficient exposure of this ductus choledochus is impossible. This last complication was present in three cases in which I operated for occlusion of the choledochus from stone. In the operations referred to, I had it in my mind to lay bare the ductus choledochus, and so I worked down through dense adhesions at the under surface of the liver, as deeply as possible, in order to search for stone; but I neither was able to find a stone (although in two cases the autopsy revealed them), nor even positive of having found the choledochus from amidst the cicatrical tissues. I therefore, in the first two cases (cases XII and XIII) established a gallic-fistula in order to prevent cholæmia, and, indeed, in two separate operations. This for the reason that in the one case (XII) the shrunken gall-bladder was difficult to apply a suture to, and in the second because the the gall itself was decomposed, and I therefore considered the dual operation safer. After the first operation the first patient showed a marked improvement of the cholæmic symptoms, but lost considerably in consequence of the loss of gall, and refused to submit to the second operation until too late. Therefore, the establishment of the gallic-intestinal fistula was not undertaken, the patient being too far gone. If it had been possible to complete this operation within a reasonable time, or possibly at the one sitting, the patient's life perhaps might have been saved. (This was the first case of any operation upon the gallic-system.) The second patient came with severe septic symptoms in consequence of diffuse suppuration of the liver and gall-passages, and died from septic poisoning. Here any procedure would have come too late to be of any avail. Neither of the patients succumbed from the effects of the operation but from their original trouble. It was interesting to me to note, that even at the autopsy, when entering the abdominal cavity through the wound made by this operation no stone or obstruction could be found. Not until both the stomach and liver had been removed, and the ductus choledochus carefully examined from the intestine on, was I able to find in the duct, close to the opening of the cystic duct, and wedged in, a stone of the size of a hazlenut. One of these stones was easily crushed with the fingers, but the other was quite hard.

In the third case an occlusion of the choledochus developed while the case was under my observation, the case being primarily one of suppuration of the gall-bladder, liver, and subphrenic space (Case XI). The patient after having shown total acholia in the fæces for four weeks, was operated upon. I was, however, unable to lay bare the choledochus, and it remained uncertain as to whether the obstruction was caused by stone or cicatrical stenosis, the indications, however, were in favor of the latter diagnosis. Finding myself completely thwarted in my endeavors to lay bare the gall-passages, I quickly determined to establish an anastomosis between the gall-bladder and the duodenum. I therefore sewed the gall-bladder to the bowel, opened both organs and then stitched the edges of the cuts together. The act of applying a suture so deep in the abdominal cavity, constituted not only a difficult but most tedious undertaking. For the sake of precaution, I wound a strip of iodoform gauze around the suture, and kept part of the abdominal wound open. The suture uniting the gall-bladder and intestine healed well, however, and the gall began to flow into the intestine. No gall was ever discharged through

* See *A. Courvoisier, Chirurgie und Pathologie der Gallenwege.*

† See *v. Langenbeck's Archives,* 42–3.

the wound. The result of the operation was truly excellent; the patient recovered rapidly, and only the sloughing out of a few silk sutures gave rise to some slight difficulties. This is the second case of cholecysto-duodenostomy that was ever performed, the first operation of the kind having been performed by Terrier.*

Rupture of the gall-stone into the abdominal cavity only occurred once in my experience. The patient was an old lady, who had suffered intensely with gall-stone colic, and the rupture occurred during one of the attacks of colic. In similar cases Küster has operated, but without being able to prevent the development of peritonitis. Rupture of the gall-stone into the intestine with subsequent ileus, I have seen in three different cases.† Two of these patients were operated upon and the one recovered, while the third patient died without operation. In the two cases that died, the autopsy revealed the perforation of the gall-bladder into the duodenum. Licherstern, Courvoisier, and Treves report several similar cases.

I will now briefly give the histories of the patients upon whose cases the foregoing remarks have been based.

Cholelithiasis; dropsy of the gall-bladder; cholecystotomy; plastic closure of the fistula; recovery.

Case I. Mrs. E., thirty-eight years old. The patient had been married for sixteen years and had borne two children, the youngest being eleven years old. For eight years she had been troubled with pains in the region of the liver, growing worse always during menstruation. Latterly she also complained of simultaneous "stomach cramps" and back-ache. Bowels sluggish, but fæces not decolorized. During the attacks the color of the face was slightly yellow.

The patient was admitted to the hospital July 2, 1890. She was well nourished. Skin slightly yellow. The liver stretched beyond the curve of the ribs to the width of two fingers. The gall-bladder could be easily felt as a semi-spherical tumor, and was painful to the touch. Urine free from gallic coloring matter. Fæces normal.

The patient was kept under observation several weeks, The size of the gall-bladder was seen to vary. All the symptoms were aggravated during menstruation. July 30, 1890.—Cholecystotomy was performed at one sitting. Longitudinal incision over the tumor; partial evacuation of the contents of the gall-bladder by puncture. The gall-bladder then stitched to the abdominal wound, and opened. A light colored shiny fluid was evacuated, two stones as large as pigeon eggs removed with forceps. The case proceeded well, and there was a large secretion of gall. On September 3 and 13, the fistula was burnt with the Paquelin cautery. On September 23, the gall-badder was closed by a union of the incision in it with a row of sutures. The abdominal cavity was then closed, and healed by first intention. The patient was discharged November 21.

During the beginning of April she again came under treatment, being in perfect health but having an abdominal hernia.

Discharged November 16 1891 as completely cured.

Cholelithiasis; dropsy of the gall-bladder; stone wedged in the cystic duct; cholecystotomy; suture and sinking of gall-bladder; recovery.

Case II. Anna V., 23 years old; working woman.

On October 31, 1890, the woman suffered from an abortion, and the subsequent uterine hæmorrhage lasted for 15 days, and was only checked by the use of the curette. Since then the patient had suffered from pain in the region of the liver.

Admitted November 29, 1890.

Uterus enlarged, flabby, and discharging blood.

Curetted and iodine injected.

Gall-bladder palpable as a round tumor.

Liver not enlarged. The gall-bladder painful as well as painful to the touch. No icterus.

December 13,1890. Cholecystotomy performed. Longitudinal incision, gall-bladder drawn forward and packed around with gauze, then incised and about 50 cubic centimeters of a viscid yellowish fluid evacuated, and two stones the size of cherries, removed from the opening of the ductus cysticus.

Gall-bladder closed with two rows of

*See Courvoisier's work on the subject.

†These have been described in my work on *Ileus, Berliner Klinik,* No. 36, pages 14 to 17.

sutures and stitched to the peritoneum of the edge of the wound. The abdomen closed until over the region of the gall-bladder suture, but subsequently—after the lapse of four days, when the stitches supporting the gall-bladder had been loosened—entirely closed. Healing by first intention.

January 13, 1891, discharged as cured. The patient was subsequently seen again after the lapse of several months, and was found to be perfectly well. There was no abdominal hernia in this case.

Cholelithiasis; dropsy of the gall-bladder; stone wedged in the cystic duct; Cholecystotomy; suture and subsequent sinking of the gall-bladder; recovery.

Case III. Mrs. L., 33 years old. Had borne many children. Had suffered for the last five years with pain in the upper abdominal region; and for several months back had had periodical attacks of colic. She had never been jaundiced. Bowels sluggish. Admitted January 6, 1891. Gall-bladder enlarged, and easily palpable under the margin of the ribs as a roundish tumor. Moderately painful to the touch. No icterus.

January 12, 1891. Cholecystotomy. Longitudinal incision. Mesentery adherent to the gall-bladder. Adhesions loosened, the gall-bladder drawn forward, and surrounded with gauze. The incision allowed the evacuation of a quantity of a light yellow, slimy fluid, and a stone the size of a huckle-berry. A second stone was found wedged in the ductus cysticus, and after many futile efforts at extraction, was easily removed by the fingers, these being inserted into the abdominal cavity, under the duct. Suture applied in two rows to the gall-bladder. Abdominal wound closed to all but two sutures, which were also closed on the fourth day. Absolutely normal course of wound. Patient discharged as cured February 9.

Cholelithiasis; dropsy of the gall-bladder; gall-stone colics; stone wedged in the cystic duct; cholecystotomy; suture and subsequent sinking of the gall-bladder; recovery.

Case IV. Mrs. S., 33 years old. Had borne several children, the last only four years previously. In the year of 1880 she had catarrh of the bladder, and retention of urine, caused by an ovarian tumor. On November 19, 1890, double ovariotomy was performed upon her in the Urban Hospital. After her child-birth in the year of 1882, colicky pains appeared in the right side of the abdomen, which were characterized by the patient as "stomach cramps." During the last pregnancy these attacks became more frequent and severe, especially after eating, and from time to time the skin assumed a slightly yellow color. On August 18, 1891, she had an unusually severe attack, and the gall-bladder was found to be enlarged.

On August 22, 1891, she was admitted to the hospital. The patient was seen to be of delicate constitution and the color of the skin slightly yellow. Below the margin of the ribs on the right side, the gall-bladder could be palpated as a round, hard and very sensitive tumor. The urine was normal and contained no gallic coloring matter.

August 24, 1891. Cholecystotomy performed. Longitudinal incision from the margin of the ribs down for 8 centimetres; and situated directly over the tumor. The gall-bladder which was found to be as large as a hen's egg, was drawn forward and bedded in gauze. Forty or fifty cubic centimetres of light gall with flakes evacuated. A stone could be felt by the finger to be imbedded, or rather wedged, in the ductus cysticus, and was removed not without considerable difficulty with a blunt hook. Gall-bladder closed with a single row of sutures. Abdominal wound closed, but a strip of iodoform gauze left between two sutures, as a drain, which was removed on the fifth day. Subsequent course without fever, but during the first few days still pain in the gall-bladder. A few weeks after her discharge some of the sutures sloughed away.

She reported November 16, 1891, as perfectly well.

Cholelithiasis; frequent gall-stone colics with icterus, and temporary occlusion of the gall-bladder; cholecystotomy; suture, and subsequent sinking of gall-bladder; passing discharge of gall; recovery.

Case V. Mrs. G., 31 years old. The patient had borne six children. Four months after the last child-birth gall-stone colics with icterus appeared (July, 1890). During the May of 1891 the severe gall-stone colics again appeared. She was admitted October 25, 1891, with a most

severe attack. Icterus appeared, and the fæces became clay-colored. On October 30, gall was again present in the fæces. During this time the gall-bladder could easily be felt as a tumor about the size of a hen's egg, just below the margin of the ribs. It was very sensitive to the touch, and this sensitiveness did not abate even after the attack had passed. After the stools had been normally colored for six days, and the icterus had disappeared, the operation of "ideal cholecystotomy" was performed on November 6, 1891, with a transverse incision along the margin of the ribs. The gall-bladder was found to contain viscid slime and many stones, the most of which of a pyramidal form with a four-sided base. The cystic duct was stuffed full of stones which were removed with the hook. In the ductus choledochus nothing was found by palpation even from the abdominal cavity. Sounding the latter was attempted, but found impossible. Suture of the gall-bladder with two rows of catgut sutures. Iodoform gauze laid over the suture. Normal course of recovery with the seventh day, and then some gall was drained out through the strips of iodoform gauze. This discontinued on the tenth day. The wound was entirely healed on November 27, 1891.

Severe cardalgia. Vomiting; enlargement of the gall-bladder; existence of gall-stone accepted; cholecystotomy; no gall-stone found; suture, and subsequent sinking of the gall-bladder. Healing of the wound; subsequent return of the cardalgia in four weeks (hysteria.)

Case VI. Mrs. G., 40 years old. Attending physician, Dr. Wulsten. Since July, 1890, the patient had severe pains in the back and abdomen, accompanied by nutritive disturbances. In November, 1890, a large subserous myoma and both ovaries were removed. The pains in the abdomen continued and concentrated themselves in the region of the stomach. They became most intense and morphine was required to afford any relief. Nutrition became greatly impaired owing to the constant vomiting; the patient became very much emaciated, losing seventy-five pounds in the course of a few months. In May, 1891, an examination was made while the patient was under the influence of an anæsthetic. A round, hard tumor could be felt in the region of the gall-bladder, and besides this, a floating kidney in the right side.

Diagnosis: Possible dropsy of the gall-bladder, with incarcerated stone in the cystic duct.

Laparotomy was performed on May 21, 1891. Incision parallel with the border of the ribs. Gall-bladder enlarged but not adherent. No stone could be felt. The liver and gall-bladder were drawn forward. The gall-bladder incised and a viscid dark green gall evacuated. Digital examination failed to reveal any stone; the gall-bladder then closed with two rows of sutures. The pylorus drawn forward, but found normal. Examination of the neighboring viscera negative. The very loose attachments of the lower lobe of the liver were reenforced by three silk sutures to the edge of the ribs. The abdominal wound closed, and the subsequent course of recovery from the operation entirely normal.

The pains ceased entirely, and the patient took and retained plenty of nourishment and increased in strength. She was discharged on August 18.

In spite of the negative result of the operation the primary beneficial change of the patient gave hopes of an ultimate complete recovery, but no sooner had the patient returned home, than the old symptoms again became manifest. Her present condition is, according to the statement of her physician, as bad as it ever was.

Carcinoma hepatis, mistaken for gall-bladder tumor; exploratory incision.

Case VII. Mrs. S., sixty years old. Until six weeks prior to admission the patient had never suffered from any symptoms of gall-stone. She became ill during the first of May with severe periodical pains in the region of the liver, and simultaneously a gradually increasing tumor became manifest, which from its form and location corresponded to a gall-bladder.

The patient was admitted on June 13, 1891.

Extending over the liver, on a perpendicular line with the nipple, and at the edge of the ribs a hard, rather flat, circular and sensitive enlargement could be felt, which was connected with the liver. No icterus, and no vomiting.

Diagnosis: While the finding was not at all typical the probabilities seemed to point to "retention-cyst" of the gall-

bladder, but the possibility of the growth being a malignant tumor was also recognized. On June 16, 1891, an exploratory incision was made, parallel with the curve of the ribs. The growth was found to be a tumor of the liver itself and very vascular. The gall-bladder, which was covered by the growth, was not enlarged. The abdominal wound was closed, but healing was delayed by phlegmons. The pains abated, but the tumor continued to grow. The patient was seen again in October; she had then ascites and knotty tumors in different parts of the abdomen. Death about the middle of November, 1891.

(*To be continued.*)

DRUNKENNESS AS A VIRTUE.

Dr. George Foy sends the following letter to the *London Medical Press*, of November 18, 1891:

Sir,—As an evidence of the altered social habits of the general public, I wish to bring a curious old volume under the notice of your readers. It was printed for E. Curl, against Catharine Street, in the Strand, London, in 1723, and is marked "Price Five Shillings." The title is as follows: "Ebrietatis Ecomium, or the Praise of Drunkenness; wherein is authentically and most evidently proved the necessity of frequently getting drunk; and that the practice of getting drunk is most ancient, primitive, and catholic. Confirmed by the example of Heathens, Turks, Infidels, Primitive Christians, Saints, Popes, Bishops, Doctors, Philosophers, Poets, Freemasons, and other men of learning in all ages. By Boniface Oinophilus, de Monte Fiascone, A. B. C."

> Vinum retificans cor hominis,
> Narratur et Prisci Catories,
> Sæpe mero caluisse virtus.
>
> HORAT.

The author lays down the following rules for getting drunk, to wit:

1. Not too often.
2. In good company.
3. With good wine.
4. At convenient times.
5. Force no one to drink.
6. Do not push drunkenness too far.

The volume ends with a postscript by F. Sans-terre, dated May 1, 1723, "*From my Garret in* Bandy-legged Walk." A year made memorable by the death of "Vanessa."

Communications.

REPORT OF A FEW LAPAROTOMIES DONE IN THE ALLEGHENY GENERAL HOSPITAL BY R. STANSBURY SUTTON, M. D., GYNÆCOLOGIST TO THE HOSPITAL.

BY MARK A. RODGERS, M. D.

(*Continued from the issue of July 9, 1892.*)

Continuing the report of Laparotomies done at the Allegheny General Hospital from the issue of July 9th, of this journal, I beg leave to submit a second series of cases which I think will prove much more interesting to lovers of abdominal surgery than those of the first report.

CASE XI. Double salpingo-oöphorectomy. Diagnosis:—menstrual epilepsy, chronic salpingitis and ovaritis. Miss R., aged 24. History negative until puberty, at which time she developed menstrual epileptic convulsions of a severe enough type that she presented many scars on various parts of her person, from falls, burns, etc., received during seizures. She had given birth to a child two years previous to her admission, and during pregnancy had experienced an abatement of the epileptic symptoms, which returned with increased severity after the birth of the infant. On examination, there appeared a small bilateral laceration of the cervix, which, however, was occasioning her no discomfort, and a mass in Douglas' pouch immobile and excessively tender, which was thought to be a prolapsed ovary.

Operation June 7th, 1892. Both ovaries were prolapsed, much congested, enlarged and firmly adherent to uterus, rectum and *cul de sac*. Both were removed. Abdomen flushed and closed. Time, twenty minutes.

Had two seizures on sixth day, at which time temperature rose to 101 $\frac{3}{5}$°. Calomel and saline purge was followed by normal temperature. No seizures from that until present time. Patient made rapid recovery and is now in good health.

CASE XII. Cholecystotomy. Diagnosis, impacted gall-stones. Mrs. B.,

aged 45. History negative, save as to hepatic colic, which had been almost incessant for several years. On admission was deeply jaundiced and suffering great pain.

Operation June 10th, 1892. An incision three inches in length was made in the right hypochondriac region, exposing the gall-bladder and liver. The upper end of the incision began a short distance above the end of the tenth rib. The liver seemed congested and the gall-bladder was enormously distended. An aspirator was introduced into the latter and about one pint of muco-purulent material withdrawn. Numerous calculi could then be felt through the cyst wall. The bladder was next stitched to the peritoneum, the wound closed above and below, and finally the viscus incised. Seventy-two stones were removed, ranging in size from an English walnut to a small pea; two of the smaller were removed from the cystic duct and one extracted with great difficulty from the common duct. The instrument used for this purpose was a small uterine curette. Time, one hour.

Jaundice almost immediately disappeared. Patient had a severe attack of colic during fourth day. Otherwise convalescence was uninterrupted. Discharged June 29th, with slight biliary fistula which was rapidly closing by granulation. Patient at that time had good appetite and was in good state of general health.

Case XIII. Double salpingo-oöphorectomy. Diagnosis,—double pyosalpinx, with pelvic peritonitis. Mrs. B., aged 40. History negative as to difficulty under consideration, save a history of long continued and excessive pelvic pain and an indistinct history of amenorrhœa. During a sojourn of one week in the hospital, her temperature registered from 99⅘° to 101⅘°. On inspection and palpation, the abdomen was found to be enlarged especially on right side, and presented a diffused tumor-like mass, extending from the umbilicus. Bimanuel examination revealed uterus firmly fixed and semi-fluctuating masses encroaching upon the vaginal vault from both sides. This patient suffered intense agony and preferred death to her miserable condition.

Operation June 11, 1892. This was the most difficult case operated in this entire series of twenty-one cases. When the abdomen was opened the omentum was found adherent to the intestines; after its separation it was so bruised and lacerated that much of it required amputation. The intestines were agglutinated by dense connective tissue, and the whole fitting down over uterus and adnexa like a cowl. In attempting to separate the adhesions the tube on the left side was ruptured and fully a quart of virulent looking pus evacuated. A line of cleavage was attained and the tube which was converted into an abscess sac of prodigious size was with the left ovary finally tied off. The operator's attention was then turned to the right side. The intestines were raised and an enormous pus tube exposed to view. This was also found bound down by adhesions, but they yielded more easily to the operator's efforts than was expected, and after ligating several quite large vascular cords of connective tissue, the tube was finally delivered intact. It was ligated and removed. The abdomen was thoroughly flushed with about eight gallons of very hot water and closed. Time on the table 45 minutes.

There was some distension on the fourth day, which was relieved by turpentine enemata. Union occurred by first intention and the patient was discharged June 26, rapidly regaining health and strength. The fact that union took place without a drop of pus, is sufficient evidence in the operator's opinion that an abundant supply of hot water is adequate for purposes of thorough disinfection.

Dr. Sutton is in accord with Tait and Price on the question of pelvic abscess, and attacks all pus accumulations in the pelvis through the abdominal wall, unless pointing has occurred in the vagina. In a case recently done at his private hospital the abscess had been discharging per rectum. The operation was followed by a fæcal fistula which, however, entirely closed within the first few weeks.

Case XIV. Double salpingo-oöphorectomy. Diagnosis: — atrophy of right ovary; left ovary cystic and enlarged. Mrs. N., aged 22. History of sterility, menorrhagia, dysmenorrhœa and great pelvic pain.

Operation June 12, 1892. Dr. Joseph Taber Johnson, of Washington, being Dr. Sutton's guest was requested by the latter to operate. The invitation was accepted and the operation was performed in accordance with Dr. Johnson's well-known

skill. No sponging or flushing. Recovered. Discharged June 23, eleven days after operation.

Case XV. Single ovariotomy. Diagnosis:—dermoid cyst. Miss S., aged 32. History of great pelvic pain, dysmenorrhœa, etc.; examination revealed fluctuating tumor in right pelvis.

Operation June 16, 1892. Cyst of right ovary size of an orange, removed intact. Containing skin and hair in interior of second daughter cyst. No sponging or flushing. Time 11 minutes. Convalescence uninterrupted. Discharged July 1.

Case XVI. Double salpingo-oöphorectomy. Diagnosis: Double pyosalpinx. Mrs. S., aged 26. Sterile for six years. Attack of gonorrhœa from husband soon after marriage. Severe attack of peritonitis while at hospital, a short time previous to operation. Examination:—large masses on both sides of uterus, latter being firmly bound down.

Operation, June 18th, 1892. Universal dense adhesions. Operation very difficult. Pus in both tubes. Tubes and ovaries on both sides removed. Abdomen flushed and closed. Time, 30 minutes. Recovered; rather tardy convalescence.

Case XVII. Single ovariotomy. Diagnosis:—solid tumor of right ovary, probably a myoma. Miss S., aged 33. Tumor first noticed five years previous to admission.

Operation, July 19th, 1892. Solid tumor of right ovary of about six pounds weight. Adhesions to abdominal parieties, uterus, bladder and floor of pelvis. This operation was also quite difficult. Pedicle was tube which required ligation before the delivery of the tumor could be effected and great difficulty was experienced in accomplishing the latter. The operator succeeded in insinuating his hand between the tumor and its pelvic adhesions, and then forcibly wrenched it from its attachments. Abdomen flushed and closed. Time, 35 minutes. Recovered. Convalescence uneventful.

Case XVIII. Intraligamentous cyst. Miss T., aged 29. History: One child seven years prior to admission; had been an invalid since that time. Large mass on examination in right pelvis. Operation, June 27th, 1892. The presenting portion of the cyst was stitched to the abdominal wound, incised and about a quart of serum and pus evacuated. The cavity was then carefully cleansed, the sutures withdrawn and the cyst enucleated. The enucleation was attended with some hæmorrhage and was quite difficult in execution. The pedicle was finally ligated with tube and round ligament, at cornu of uterus. Left ovary was normal and therefore not disturbed. No flushing. Time, 30 minutes. Recovered. Convalescence uneventful.

Case XIX. Double salpingo-oöphorectomy and anterior fixation of uterus. Diagnosis:—procidentia uteri, both ovaries prolapsed and hypertrophied. Mrs. S., aged 42. History:—seven children, last, five years of age. Patient had been chronic invalid, bed-ridden much of the time since birth of last child. On examination both ovaries were prolapsed, hypertrophied and exquisitely tender and the uterus procidnous.

Operation, June 28th, 1892. Abdomen very fat and flabby. Both ovaries were large, cystic and hæmorrhagic; both removed and uterus stitched to lower angle of wound, with two buried silk-worm gut sutures. No flushing or sponging. Uneventful convalescence.

Case XX. Double salpingo-oöphorectomy. Diagnosis, prolapsed ovaries, chronic salpingitis. Miss C., aged 19. Bore one child at 17. Menorrhagia and chronic invalidism.

Operation June 29th, 1892. Both ovaries very large and cystic; chronic salpingitis. Tubes and ovaries on both sides removed. No flushing or sponging. Time, 15 minutes. Recovered; convalescence uneventful.

Case XXI. Supravaginal hysterectomy. Diagnosis:—fibroid uterus, chronic isalpingitis and ovaritis and pelvic pertonitis. Mrs. L., aged 46. Mother of seven children. Violent uterine hæmorrhages. Uterus on examination large and fixed.

Operation July 2nd, 1892. Right tube much enlarged and ovary composed of dense connective tissue and contained about four ounces peculiar looking fluid. The ovarian parenchyma was completely obliterated. Tube twisted once upon itself and with ovary firmly embedded in a mass of old dense adhesions and in similar condition, pathologically, as right side. Uterus bound firmly to promontory of sacrum and sigmoid flexure of colon. After separation of adhesions the uterus was drawn through the abdominal wound, bringing with it the sigmoid, still attached to the left horn. This was torn off and

returned to the cavity. The uterus was now discovered to be so injured that it was deemed wise to amputate it. An elastic ligature was consequently passed around the cervix. Attention was then turned toward the hæmorrhage, which had all along been very profuse. It was soon controlled after which two hysterectomy pins were passed above the ligature, the uterus amputated and the cervical canal seared with a Paquelin cautery. The operation then proceeded after the method of Hegar, e. g.:—The peritoneum was stitched with catgut continuously, below the ligature, and closed for the distance of about one inch above and below the stump, while the muscles and superficial tissue were allowed to remain open. The wound above and below was closed with deep sutures, in the ordinary manner. The tissues were then separated from the stump and the cavity firmly packed with iodoform gauze. The stump was next dusted with powdered subsulphate of iron and the whole closed in the usual manner.

Dressing changed on third, sixth and eleventh days; at latter dressing the stump was found to have separated and the ligature was consequently removed, leaving a cavity filled with healthy granulations. Not a particle of odor was noticeable at any time, the stump being completely mummified by the styptic. Patient made rapid recovery, sitting up in bed on sixteenth day.

Dr. Sutton is very favorably impressed with the elastic ligature. He states that his experience with it in the past two years was preceded by the loss of a case from secondary hæmorrhage, in which he used the *ecraseur* of Koeberle. In this instance the neck of the uterus was soft and did not sufficiently resist the constricting wire, and the result as above followed, over a quart of blood escaping into the dressings before being discovered by the nurse. Since that event he has used the elastic ligature and has not lost a case.

The conclusion of this series of cases closes the reports until after Sept. 1st, 1892, when the gynæcological annex to the hospital will be re-opened. I shall then report the interesting cases as they present from time to time.

In summing up the work at this hospital since March 26, 1892, we find that there have been 21 abdominal sections, with 19 recoveries and two deaths.

THE EFFECT OF DISEASES OF THE EAR UPON THE GENERAL CONDITION.*

By WILLIAM CHEATHAM, M. D.,
PROFESSOR OF DISEASES OF THE EYE, EAR, THROAT AND NOSE, LOUISVILLE MEDICAL COLLEGE; EYE, EAR, THROAT AND NOSE PHYSICIAN, LOUISVILLE CITY HOSPITAL.

It shall be my endeavor in this short paper to cite some cases which have come under my observation in recent years, hoping they may be of profit not only to the general practitioner, but also to the aurist. The ear and its diseases appear to be less understood by the general practitioner than diseases of the eye, yet the former are of much more consequence than those of the latter, as more serious results are liable to follow their neglect.

The subject of this paper was brought to my mind on the day I received a note from our most worthy Secretary, asking me to prepare an article for this meeting of your Society. A prominent lawyer of our city had just made one of his monthly visits to my office to have his ear cleansed, saying his nausea had returned. On that day this gentleman said to me, "Doctor, you cured me three years ago of a cough that had troubled me much for several years, that had resisted all previous treatment." The cough has never returned. I remembered syringing from his ear a mass of inspissated wax and pus, and relieving him by treatment of quite an acute attack of inflammation of his external auditory canal. As I was wiping out his ear on the day of this conversation it made him cough, and recalled to him what relief I had given him by removing that mass three years before. Since then he has visited me frequently complaining of nausea; he has what we call necrosis of the attic of the middle ear, which has never healed, suppurating just the slightest all the time, and every four or six weeks pastes over the upper and outer parts of the external auditory canal with dried pus. When this accumulates to a certain extent he suffers a great deal from nausea and

*Read before the Mitchell District Medical Society at West Baden, Indiana, July 7, 1892.

comes in to have me remove it. This I do and relieve his nausea until there is another accumulation. His first reflex trouble was a cough; this has been replaced by nausea. The suppurating surface in this case has no connection with the middle ear cavity.

Reflex symptoms of this kind are not uncommon; in all cases of obscure cough which I am called upon to treat, it is part of my routine examination to look into the ears. Auditory canals of different indiduals differ very much in sensitiveness, as that of other parts of the body of the same individuals do. But that sneezing, cough, vomiting and even epilepsy may be the result of reflex irritation from the external auditory canal is beyond question. Fabucius, of Hilden, quoted by Roosa and other authorities on diseases of of the ear, reports a case of a girl ten years of age, who put a small glass ball in her ear, who was finally seized with hemicrania, anæsthesia of the left side of the body, alternating with severe pain, until at last epileptic attacks occurred, with other symptoms. Fabucius wrote his friend Bauhinus, that he had cured the child by removal of the foreign body. A Dr. Kupper, as quoted by Roosa, reported a case of epilepsy the result of a foreign body in the external auditory canal, and another of cerebral irritation the result of impacted wax; these cases can be easily multiplied. Some years ago I reported a case of a young lady from Central Kentucky, who had been treated for a persistent hacking cough; and had also been treated by a noted specialist of Chicago for some obscure nerve disease, whom I relieved entirely by removing from one ear a mass of impacted wax. Woakes not only admits that ear cough is common, but says by continued irritation of the auricular branch of the pneumogastric, derangement of the innervation of the laryngeal muscles may follow. Spasmodic croup he gives as one of the possibilities of this reflex action. Woakes traces the irritation (Roosa says, p. 206): *First*, from the vaso-motor fibres associated with the auricular branch of the pneumogastric. *Second*, to the secondary vasomotor center the ganglion of the pneumogastric, whence he says it is deflected through sympathetic fasciculus, to the first crevical ganglion; *third*, thence by the nervi molles, to the vessels distributed to the mucous membrane of the larynx. He rejects the simple idea that the morbid impression is conducted along the sensitive fibres, from one region to another.

There yet remains in the minds of good men a doubt of the presence of a branch of the vagus in the external auditory canal. Quain and Fox says the branch of the pneumogastric supplies only the posterior part of the auricle, yet Fox has written one of the most extensive articles on ear cough ever printed. Clarke and Fox say ear cough has its origin "in the fibers of the fifth cerebral nerve distributed to the auditory canal." It remains a fact that ear cough is not uncommon, and that the weight of authority gives a branch of the pneumogastric nerve, distributed to the external auditory canal. Tissol reports a case of uncontrollable cough, the result of touching the external auditory canal. Teehlin reported with other cases, a case in the person of a military officer, who vomited considerably when ever his external auditory canal was touched. This sensitiveness may be in but one canal.

General Symptoms from Accumulations of Cerumen in the Auditory Canal: Aitken (*British Medical Journal*, No. 1630, p. 652) records three interesting observations in which general symptoms disappear after the removal of accumulations of cerumen in the auditory canal. In a little girl, eight years of age, with incessant cough, bad nights, frequent night-terrors, loss of appetite, and emaciation, without physical signs of pulmonary disease, one of the ears was found blocked with wax. In a man, eighty-one years of age, with restlessness, tremor, derangement of digestion, and deafness, the ears were found filled with large masses of hardened wax. A girl, eleven years of age, with a tuberculous family history, presented elevation of temperature, frequency and irregularity of pulse, but without other signs of organic disease. An accumulation of wax was found in the ear.

Not only wax and foreign bodies, but eczema, aspergillus, and furunculous inflammation of the external auditory canal may produce such symptoms as referred to.

Inflammations of the middle ear, and the danger therefrom I believe are beginning to be better understood than those of the external ear. Abscess of the brain, meningitis, pyæmia, phlebitis, mastoid

periostitis and necrosis, kidney complications from continued suppuration, are all well known results of suppuration of the middle ear. Abscesses of the brain (and middle ear suppuration produces a large majority of them) are getting rather common; many of them are now relieved by the trephine and incision or aspiration.

Cases of phlebitis as a result of middle ear suppuration are now relieved by tying the jugulars and curetting the brain sinuses. I have recently had a case of this latter trouble die before the mastoid could even be opened. I have recently seen a case of pyæmia in a stout healthy boy from Louisiana, the result of a subacute suppuration of the middle ear. Within the last week I have had two very bad cases of vertigo the result of acute suppuration of the middle ear. These cases are quite common. The last two cases mentioned were the result of pressure. Chronic catarrhal inflammations of the middle ear quite frequently cause vertigo. I have quite a number of such cases on hand, which have been treated by good men for cerebral and spinal trouble, as causing the vertigo. I have a lady under my charge now, who has frequent severe attacks of vertigo, which can be relieved only by the Eustachian bougie to dilate the tube, then inflation by the Eustachian catheter. Air cannot be gotten into the middle ear in this case except by use first of the bougie. I have one case of aural vertigo, in which the mouth of the Eustachian tube is dislocated, in which I had to pass the Eustachian catheter through the nose, and watch the instrument post-rhinoscopically and make a very long curious bend in the catheter before I could get air into the tube. Vertigo from disease of the internal ear is still better understood than that depending upon disease of either the external or middle ear. Meniere's disease has long been written of. The pathology of the disease has changed some in the last few years. These few notes I then hope will remind some of the gentlemen present, that in case of vertigo, cases of obscure cough and nausea, and other affections referred to, and some not mentioned, an examination of the ears should not be neglected. That suppuration of the middle ear is always dangerous; that the advice to let such cases alone, that they will outgrow it, is a thing of the past; that suppuration of the middle ear can cause pyæmia without involving the brain; such a case I forgot to mention, I saw with Drs. Bodine and Yandell, in which with other abscesses, there was one over the left scapula, which held about two pints of pus. Such cases cannot, of course, be relieved unless the cause is corrected. I could multiply instances enough of all the complications reported in this paper to fill many pages, but think enough has been said to show what diseases of the external, middle aud internal ears can do, how they affect the general economy, and consequently how important it is to attend to them early and knowingly.

THE PREVENTION OF PURULENT OPHTHALMIA NEONATORUM AS A CAUSE OF BLINDNESS.

Frederick E. Cheney (*Boston Medical and Surgical Journal*, April 14, 1892.) prefers the title of Purulent Ophthalmia Neonatorum to that which is usually used to describe this condition, namely, Ophthalmia Neonatorum, for that affection which so often leads to blindness. The total per cent. of those blind being due to this cause is from 18.6 per cent. at the Perkins Institution for the Blind, to 26.02 per cent. in the asylums of Switzerland. Owing to the importance of this subject the New York Legislature has passed the following Act:

Section 1. Should any midwife or nurse having charge of an infant in this State notice that one or both eyes of such infants are reddened or inflamed at any time within two weeks after its birth, it shall be the duty of such mid-wife or nurse so having charge of such infant to report the fact in writing within six hours to the health officer, or some equally qualified practitioner of medicine of the city, town or district in which the parents of the child reside.

Sec. 2. Any failure to comply with the provisions of this Act shall be punishable by a fine not to exceed one hundred dollars, or imprisonment not to exceed six months, or both.

Sec. 3. This Act shall take effect on the first day of September, 1890.

Too little time has elapsed since the passage of the Act for statistics, but it is recommended that other states pass similar laws.

THE EFFECTS OF INTRA-NASAL OBSTRUCTION ON THE GENERAL HEALTH.*

By LEWIS C. CLINE, M. D.,
INDIANAPOLIS, INDIANA.

Nearly, if not every one can recall the time when they have experienced and felt the discomfort and depressing influence of an acute catarrhal inflammation of the mucous membranes of the nose, manifested by hyperæmia and hypersecretion, sneezing and obstruction, complete or partial, to the passage of air.

Only by a little careful thought on this subject do we realize the import of a clean, unobstructed breath-way through the natural channel. If stenosis from an acute cold of short duration is so potent in depressing one physically and mentally, what must be the effects, physically and mentally, of one who has permanent nasal obstruction?

Nasal obstruction in infancy is a matter of serious importance, as it may, in extreme cases, lead to paroxysms of dyspnœa and pulmonary engorgement, or may subject the child to starvation through inability to nurse. Every physician of experience can recall cases of fretful, ill-nourished babes from this cause. The moment the proper supply of air is diminished, the whole economy suffers for nutrition from deficient oxygenation of the blood. Typical examples of this are seen by every practitioner in children suffering from adenoid growths in the vault and enlarged tonsils, which give rise to the peculiar stupid facial expression. These children will all give histories of impaired appetites, restless nights with nightmare, directly in proportion to the obstruction, and no class of cases will respond more quickly to permanent improvement than they when the stenosis is relieved. Many of these cases can be traced directly to disturbed digestion and faulty nutrition, while the majority in children are due to traumatism, scarlet fever, diphtheria and measles. He, who gives the subject attention, cannot help being impressed with the intimate relation existing between naso-pharyngeal obstruction and the general health, as manifested by the stupid expression, muffled voice, faded complexion, flabby muscles, pinched features, spare forms, treacherous appetite, rebellious stomach, with strong tendencies to neuralgia, headache, worry, and loss of memory. In all cases of nasal stenosis, some or all of these symptoms are met with.

Those that are most liable to nasal obstruction from hypertrophy apart from the causes mentioned are not, as may be supposed, those that live out and are exposed to climatic changes, but on the contrary, they are those who live in-doors, such as work in dusty factories, stores, shops, and crowded cities where they do not have sufficient exercise in the open air and sunlight.

Thus we find that these cases come principally from three sources, viz:—1st. Traumatisms as falls or blows on the nose producing displacement of the septum, leading to hypertrophy and stenosis. 2nd. Scarlet fever, measles and diphtheria are a very common cause of stenosis in the young, leading to hypertrophy of the glandular and epithelial structures. 3d. From those who are most closely confined and suffer from the want of exercise and sunlight. These points should always be kept in mind, as they furnish the key to successful treatment.

It is my firm belief from observation and experience, in some cases, that many infants are treated with all sorts of drugs and soothing syrups for colic, when there is nothing the matter but ear-ache, caused by nasal stenosis, and all that is required to give relief is to clear the nose and inflate the ear. Many cases of asthma and sick head-aches can be traced to hypertrophy of the turbinates. Perhaps the following cases will best illustrate my text in adult cases:

Case I.—Mr. W., age 37, locomotive engineer, was referred to me for treatment April 11th, 1892, and gave the following history. For five years he had been a great sufferer from headaches. During the last two years, he had gradually grown worse, necessitating his laying off occasionally. Until three months ago when he had a great tendency to go asleep in spite of the effort to remain awake. On awaking from one of these naps he could not tell where he was or what station he had passed last, nor could he tell whether he had orders to run or not. His firemen had to tell him where he was and what

*Read before the Mitchell District Medical Society, at West Baden, July 7 and 8, 1892.

his orders were before he could realize the situation. This so frightened him that he took a leave of absence for two months. On examination I found his left nostril completely filled with a spur and deflected septum. The posterior ends of both inferior turbinates were hypertrophied, filling up the post-nasal space. The anterior tip of the middle turbinate on the right side was much enlarged, forming a hard tumor pressing against the septum. The pharynx was very dry and covered with a tough tenacious mucus. He could get but little air through the right side and his hearing was impaired. I began the treatment by removing the large nodule of hypertrophied tissue with the snare and the septal spur with the saw. As soon as the stenosis and pressure were relieved and breathing re-established, the headache was gone with all of the other symptoms complained of. He has now been running his engine for six weeks with but one slight attack of headache which followed getting wet and cold on a night run.

This patient says he has not felt as well in five years.

Case II.—Mr. R., pastor of one of our principal churches, and a great worker in charity organizations, consulted me on May 25th, 1892, on account of difficulty of breathing through the nose and the loss of power to concentrate his mind on his work or on any subject for any length of time. He was very forgetful, and was constantly annoyed by things that formerly did not concern him. He had become despondent, a thing foreign to his real self. In his own words, "To perform my work is like the task of climbing a marble monument with no foot-holds and nothing to grasp." Rhinoscopic examination revealed two large masses of hypertrophied tissue almost filling the post. nares, projecting well down over the soft palate. The anterior portion of the inferior turbinates was swollen and pressed against the septum. On removing the masses with a cold snare the patient experienced great relief, and as the treatment progresses the symptoms gradually subside. The case is still under treatment.

Case III.—On Feb. 8th, 1892, Mrs. O'B. was referred to me for examination. She had suffered repeated attacks of sick headache, more or less, for fifteen years, and had suffered no other sickness except that incident to child-birth. She stated that during the last three years her malady had gradually grown worse, so much so that during the last year she had developed a fear of becoming insane. She stated that during the last five years she thought she had spent as much as one day each week in bed from this cause. She also stated that at various times during all these years she had been treated for what her family physician called female trouble, to which he ascribed the headache, although he had never made an examination. Examination in this case revealed a hard tumor-like nodule, the size of a hazlenut, embracing the anterior end of the right turbinate body, pressing hard against the septum. There was some hypertrophy of both middle and inferior turbinates posteriorly, sufficient to cause stenosis when in the recumbent position. She, too, complained of lassitude, weariness and despondency. I removed the tumor with a snare and cauterized the hypertrophies, and to use her own language, "My happy girlhood disposition has returned." This case was under observation to May 15th, a period of over three months, up to which time there had been no recurrence of any of the old trouble.

I might extend these remarks to many like cases, but having already tired your patience, I will leave the subject with a plea for more rhinology and less stereotyped prescribing.

SALIPYRIN.

This body is a chemical compound of phenazone (antipyrin) and salicylic acid. In every one hundred parts there are 57.7 phenazone and 42.3 salicylic acid. It is prepared at the chemical works of Mr. J. D. Riedel, of Berlin, and has lately been introduced as a remedy which combines the physiological action of phenazone and that of salicylic-acid. There are some particulars in which salipyrin is said to differ advantageously from either of its constituents. It is stated that salipyrin is therapeutically effective without producing any functional disturbance. It occurs in the form of very small colorless crystals; the taste is not at all unpleasant, and may be described as slightly astringent and acid. It is very sparingly soluble in water, freely in alcohol. On account of its insolubility in water salipyrin is best administered in its compressed state or in cachets.

A FEW NOTABLE REMEDIES.*

By S. E. MUNFORD, M. D.,
PRINCETON, INDIANA.

Strychnia.—As this remedy is usually prescribed, I doubt if we are ever sure of benefit from it. It is believed to be a tonic in worn-out nervous conditions and to aid in the treatment of gastro-intestinal troubles. It is prescribed in doses from $\frac{1}{60}$ to $\frac{1}{100}$ of a grain, combined usually with iron and the bitter remedies. To learn to respect the drug we need to give it in a case of acute general chorea, according to the dosage instituted and practiced by Trousseau, or as near thereto as the courage of the practitioner will allow. He dissolved one grain of the sulphate in twenty teaspoonfuls of syrup (℥iiss), each teaspoonful containing therefore $\frac{1}{20}$ grain of the salt. With children, according to the age, he administered at the beginning from one to three teaspoonfuls per day. The doses to be given at equal intervals of time during the day, so the effect may be watched. If the dose of three teaspoonfuls each day is well borne it is continued for two days and increased by one teaspoonful. After another two days the dose is increased by another spoonful, and so on until six teaspoonfuls are taken in the course of the day, *always at equal intervals of time.* When this dose has been reached two teaspoonfuls are given three times a day and increased according to the rules of the first course. Then a teaspoonful ($\frac{1}{3}$ grain) may be given and pushed until three, four or even five of these doses are given per day. In the case of adults the dose from the beginning may be two teaspoonfuls and increased to two grains of the drug daily. The administration of the remedy attended by the closest surveillance should not be stopped short of the physiological effects. When the patient complains of some stiffness of the jaws, slight giddiness, or stiffness of muscles of neck and back, the ascending scale of dosage should be stopped, and if the choreic manifestations are disappearing the dose may be lessened. I have never had occasion to reach the outer limits of administration of the drug according to Trosseau's rule, for the reason that my cases have yielded before that limit was reached. The doses are heroic and the method has been denounced as dangerous. I am satisfied from my own observation that an individual with a violent attack of chorea is wonderfully tolerant of the drug. It is pretty safe to follow the master clinician.

Morphia.—I have only to remark with reference to this drug that it is given usually in larger doses than are needed to secure the desired effect. When we deal with spasmodic, hepatic, or renal colic a full dose is imperative. In a majority of the cases in which morphia is administered one twenty-fourth of a grain will be found to be sufficient. One-fortieth or even one-sixtieth of a grain will relieve moderate pain and quiet a bed-wearied patient. I spent last summer in bed and had some experience with this remedy. Two grains of the sulphate of morphia were sufficient for the pains and weariness of the entire attack. I use the hypodermic tablets for internal use, grain $\frac{1}{4}$, and divide into the dose I may want by teaspoonfuls of water.

Phosphate of Soda.—This drug is cholagogue in effect. If continued in sufficient doses it increases the biliary flow. It is helpful in all cases of gastro-intestinal catarrh. In the duodenal catarrh of children attended with mild fever and slight jaundice, ten to twenty grains of the phosphate in solution, repeated several times a day, give relief. I call up the remedy on this occasion to say that it is the one reliable agent in all the list of remedies for the prevention of the inspissation of bile and the crystallization of cholesterine, resulting in the formation of gall-stones. It will not relieve the pain occasioned by a calculus in its exodus from the gall-bladder. It will not dissolve concretions already formed; but given continuously in large doses—six to eight drachms daily—it will certainly stop the formation of bilary concretions and cure the patient. A few years since I saw a woman who had suffered for two years with frequent recurrences of hepatic colic. Gall-stones had been passed, leaving no doubt as to the diagnosis. The patient was reduced in flesh, bore food badly, and was thoroughly dyed with the bile stain. Several good practitioners had seen her as consultants at different times, and I said to the attending physician: "There is no opportunity for me. You have with the aid of these men doubtless compassed the whole field of

* Read before the Mitchell District Medical Society at West Baden, Indiana, July 7–8, 1892.

therapy." But when he told me of the remedies used phosphate of soda was not in the list, we gave this remedy and cured the patient.

To Roberts Bartholow we are indebted for having indicated to the profession a remedy well-nigh magical in preventing the formation of biliary concretions.

HYPNOTICS.

By E. P. EASLEY, M. D.,
NEW ALBANY, INDIANA.

I wish to disclaim at the outset the knowledge of anything new in hypnology. My experience with these agents has doubtless been quite similar to yours, but by giving you my views of them your own will be strengthened or confirmed, and in this way I trust my remark may be of benefit to you.

We are often confronted with cases where it is imperative to produce sleep, and the choice of a hypnotic then becomes a matter of great moment. The list of somniferous drugs is long and quite a number of them reliable, but no one of them is applicable to all cases or ages. So many things must be considered in making a selection that the question is indeed one of great perplexity. We desire to give an opiate for instance. Constipation may exist as a contra-indication, or the patient may be intolerant of opium in any of its forms. Again, a weak heart may contra-indicate the employment of chloral or sulfonal. Paraldehyde and somnal are so often repugnant to the taste as to be inadmissible, and so on by exclusion every hypnotic may be eliminated from the list. Here we can only make choice of the least evil, select the agent having certain merits and demerits, it is difficult to decide which is the most valuable, which one is acceptable in the greatest number of cases. Bromidia should have, perhaps, first place with sulfonal a close second. The former, containing cannabis indica, a heart tonic, can be pushed further than can chloral alone owing to its depressing powers.

Sulfonal in doses of 20 to 40 grains often acts magically. It frequently fails altogether however. It should be given in solutions, or it may pass entirely through the alimentary canal undissolved. This I have frequently observed. It should be administered four to six hours before bedtime as its action is slow. It has the disadvantage of being followed by stupor and muscular exhaustion continuing through the following day and besides is not altogether free from danger, great depression sometimes following its use. When sleeplessness is due to pain, then opium or some of its preparations is the remedy. Morphia given hypodermically is the best. Papine is a most excellent form of opium, being almost wholly free from the disagreeable features that attach to the other preparations of this drug, and is well tolerated by very young children. One drachm of it is equivalent to an eighth of a grain of morphine. It acts peculiarly well in the wakefulness of lying-in women.

The syrup of Dover's powder I have found to act well as a hypnotic in typhoid fever. Codeia is not reliable and makes the throat and tongue very dry with a disagreeable taste.

Antifebrin has some hypnotic properties, and by relieving pain invites sleep. The same is true of the other analgesics.

Paraldehyde is seen at its best in the wakefulness of delirium tremens. Its nasty taste is unbearable to any one in his senses. Chloralamid in 20 to 40 grain doses is a favorite with some, but I have never found it effective. Bromide of potash scarcely deserves the name of a hypnotic, though as a placebo it may be of some use.

We have no ideal hypnotic unless it be, according to the newspaper paragrapher, the modern sermon. If we believed him, that is almost sure to "weigh the eyelids down and steep the senses in forgetfulness," and is more potent than all the drowsy syrups in the world. Then there are no contra-indications to its use. It is applicable alike to young and old. It has no disagreeable after-effects. It begets no *habit*, is easy of administration, and is cheap enough, being had without money and without price.

We should always bear in mind that there are many auxiliaries we may employ to aid the action of hypnotics. The condition of the bed should be made comfortable, the light and temperature properly regulated, company excluded, and any noise prevented, and the patient advised that his medicine is given for the purpose of producing sleep.

*Read before the Mitchell District Medical Society July 7th, and 8th, 1892.

Society Reports.

MITCHELL DISTRICT MEDICAL SOCIETY.

Twenty-second Annual Meeting Held at West Baden, Indiana, July 7th and 8th, 1892.

FIRST DAY—AFTERNOON SESSION.

The Society convened in the hall of the West Baden Hotel, and was called to order at 2 P. M., by the President, Dr. E. S. Elder, of Indianapolis.

After the transaction of some miscellaneous business, the reading of papers was proceeded with. The first paper read was by Dr. C. W. Murphy, of Salem, Indiana, entitled

THE COAL TAR DERIVATIVES; THEIR USE AND ABUSE.

Antipyrin, acetanilid, antikamnia and phenacetine being the most frequently used and important of the newly discovered chemical agents, the speaker's remarks were confined principally to their consideration. Antifebrin and acetanilid are the same articles under different names. When the physician prescribes acetanilid he gives its pharmaceutical name; when he prescribes antifebrin he gives its proprietary name; the former is very cheap, the latter more expensive. Both are said to possess the same therapeutical effects, but a somewhat extended use of each one leads the author to believe that for uniform activity antifebrin is the more reliable. As there are no restrictions on the manufacture of acetanilid it is easy to understand how, as in the manufacture of other drugs, an impure article is sometimes placed upon the market.

All of these agents come under the head of anodynes or analgesics, possessing the property of lessening the sensibility of the nerve centers or their peripheral extremities, but in varying degrees. They are also antipyretic in action, and it should never be overlooked that their effect on the system when fever is present is much more powerful than when it is absent; that doses of considerable size can be given for the relief of pain with impunity in the absence of a rise of temperature, that would bring on a fatal collapse in high febrile conditions. While opium will always stand at the head of anodynes, its objectionable features of generally inducing constipation, cephalalgia, nausea and deranged digestion cause us to make use of the less harmful remedies for the relief of pain in a large class of ailments. As an anodyne, antipyrin he believes to be the most powerful of all the aromatic series. It is especially useful in rheumatism as a palliative in relieving pain, reducing the temperature and procuring sleep at night. In facial neuralgia, migraine, sciatica, pruritus and neuritis it is an excellent remedy for the relief of the pain. The dose should be ten or fifteen grains, and if the pain is not relieved in one or two hours, repeat the dose. Antikamnia, acetanilid and phenacetine are also useful in hemicrania; and all four can be depended upon for the certain relief of hyperæmic headaches. The speaker has many patients who prevent paroxysms of sick headache by one or two doses of antifebrin of six to eight grains each. Some get relief from antipyrin when antifebrin fails. He had used phenacetine in a number of cases of pertussis, and believes it serves a useful purpose in diminishing the severity and frequency of the paroxysms of coughing. For the relief of enteralgia, gastralgia, and other nervous affections of the bowels, dependence cannot be placed upon any of these; but antikamnia has given relief in a number of cases of the lighter forms of these affections. All of the series have a wide range of usefulness in the treatment of *la grippe* in relieving the severe muscular and neuralgic pains and in reducing the fever. He had cured in three days an eighteen year old girl affected with choreic movements of the left arm, neck and face of uncertain ætiology by giving ten grain doses of antipyrin three times a day. He had also used antifebrin and antipyrin successfully in ten to twelve grain doses in simple nervous insomnia.

The use of all antipyretic remedies must be persisted in until the desired end—the reduction of temperature,—is secured; but the peculiarities of each patient must be studied and these agents must be administered in a way to suit each individual case. A dose that would give the desired result at one period of a disease might prove insufficient or excessive at another period; and a dose that would lower a temperature to the required degree in one individual might require double that amount to get

the same result in another. Many authorities recommend giving five to ten grains regularly every three or four hours. This practice should be deprecated, for such a quantitity is likely to disintegrate large numbers of red corpuscles, cause blueness of the lips, cold extremities, excessive sweating, subnormal temperature and such untoward effects would more than counterbalance the good accomplished. It is well known that in nearly all fevers there is an evening exacerbation; usually the fever rapidly declines after midnight, and does not rise again until 10 or 11 a. m., and sometimes not until 2 or 3 in the afternoon. A powder of seven or ten grains in the morning when the temperature has risen to 103° will generally keep it down below the point until 7 or 8 p. m., and occasionally it is sufficient for the twenty-four hours; but if it comes up again any time in the afternoon or evening another dose is given. Should one dose fail to make an impression on the fever, which but seldom occurs, the author gives another dose at the expiration of two hours. In this manner, with from one to three doses the temperature in almost all fevers is easily maintained below 103°; and as already stated, it prevents undue tissue waste, lessens nervous irritability, promotes sleep, prevents delirium and complications, and therefore lessens the mortality.

The essayist in conclusion said that the opinion was entertained by many that the antipyretic form of medication does more harm than good; but he believes that such a conclusion is based upon improper dosage and too frequent administration.

Dr. William Bailey, of Louisville, has not prescribed antipyrin for years because of the disagreeable effects observed following its administration. He does not prescribe antikamnia because it is not strictly one of the coal tar derivatives, but a made up preparation, and ought not, in his opinion, be prescribed. He uses phenacetine more frequently than all of the others together for the reduction of temperature, and gives it without hesitation under all circumstances. His method in treatment of typhoid fever is to take care of the patients, feed them carefully, treat them with phenacetine and salol, and disinfect the alimentary canal by the nitrate of silver.

Dr. E. D. Laughlin, of Orleans, Indiana, thought the profession was down on antikamnia and it had a right to be; that its antipyretic properties are entirely owing to the amount of acetanilid that it contains, 75 per cent. of acetanilid, and 25 per cent. of bicarbonate of potash, the preparation being made by a firm in St. Louis. He found penacetine an excellent thing in pertussis and whooping cough when properly administered, three times a day. He had been able to control the paroxysms of cough with it. In typhoid fever he uses acetanilid in connection with other drugs. As an antipyretic he uses it almost exclusively. He has no disposition to change for the reason that it gave him satisfaction. He thought if bicarbonate of soda with acetanilid had been taken together in the case mentioned, the headache might have been relieved.

Dr. J. M. Mathews, of Louisville, could see no justifiable reason why antikamnia should be ruled out of the list of remedies mentioned, because it is a combination and put up by some house in St. Louis. The speaker said he had been a sufferer from periodical headaches all his lifetime; he had tried the coal tar derivatives, some of them acting fairly well, others doing him injury, but antikamnia in his own case had given entire satisfaction, so much so that when he has an attack he can stop it almost instantly with antikamnia in 15 or 20 grain doses.

Dr. James T. Ball, of Judson, Indiana, does not use the preparation of antikamnia as put up by the St. Louis firm, but makes a combination himself. It is cheaper, and he considers it the safest of all the preparations he has used. To four ounces of acetanilid, he adds one ounce each of bicarbonate of soda and salol, triturating thoroughly. This combination is identical both in appearance and effect with the preparation manufactured in St. Louis.

Dr. Dudley S. Reynolds, of Louisville, said the paper awakened in his mind a consideration of the whole subject of the treatment of the inflammatory, zymotic fevers, antipyresis, etc. In 1882 a discussion of Brand's method of treating typhoid fever was extensively indulged in by the French Society for the Advancement of Science. An eminent Frenchman had been making experiments with salicin, quinine, and some of the other alkaloids of the cinchona bark. All the great clini-

cians of France took part in the discussion. The impression was that high temperature means disintegration of tissue; it means the active processes of fermentation, carefully studied most all the remedial agents employed against these processes will convince one that they are in the nature of anti-ferments. In the chronic inflammations of the so-called rheumatic people, especially the chronic inflammations of the ciliary body of the iris, all the different kinds of medicine used in the treatment of high temperature had been tried—all the eliminating agents, all the depleting agents and mercurial drugs, which had so long been in high esteem by the profession had almost entirely passed out of use. We now find phenacetine, salol, salicylate of sodium, and more rarely pilocarpine bring about not only reduction of pain, discomfort, and of the general bodily temperature, which is always elevated in inflammations of the ciliary body, but actually dissipate the inflammatory process by opening up the lymph channels and tubes by destroying the ferment that occludes them, whether by dissolving some morbid effusion or by general diffusion it is difficult to say, yet the conviction in the minds of Frenchmen was that antipyretics are after all anti-zymotics, those agents which arrest fermentation.

Dr. E. S. Elder, of Indianapolis, expressed his appreciation of the paper, and was glad that the author had taken such a bold stand in favor of antipyretic medication, as he believed that an unfounded prejudice had been created against their use by certain members of the profession who claim that antipyretics assist in producing heart failure. He believed that the injury charged to antipyretic medication resulted from continued high temperature, which meant increased metabolism or a burning up of the tissues, which of itself was disintegrating, and weakening. Dr. Elder uses phenacetine largely in the place of antifebrin. Antipyrin he had not used for some time. He relies both upon acetanilid and phenacetine. He considers it good practice in the use of antipyretic remedies to combine with them some heart tonic, such as strychnia or digitalis.

Dr. C. W. Murphy, of Salem, said if there was depression of the heart he used a cardiac tonic, otherwise not. He sometimes uses digitalis and nux vomica in combination. The principal reason for th condemnation of antipyretic medication by certain members of the profession he thought was due to an improper administration of the remedies themselves; that they were given in too large and frequent doses.

Dr. S. H. Charlton, of Seymour, Indiana, asked Dr. Murphy in what doses would he consider it safe to use these remedies, and how often. His experience was in favor of giving them in small doses. Five grains of antifebrin were as many as he gives, repeated every three or four hours. He had treated cases in the country by sending these remedies in connection with other medicines without seeing the cases. He also desired to ask whether the essayist or any other gentleman had used antipyrin or any of the coal tar derivatives in the treatment of cerebro-spinal meningitis.

Dr. Murphy said he did not use phenactine in the treatment of any kind of fever, that it was dangerous on account of its depressing effect upon the heart. As stated in the paper, he uses antifebrin in reducing the fever. When the temperature reaches 103° he gives it in from seven to ten grain doses according to the physical condition of the patient. Five or seven grains he considers sufficient in ordinary cases to reduce temperature. If it does not reduce it in two hours, he would repeat the dose. He had had no experience with antipyretics in treatment of cerebro-spinal meningitis.

Dr. William Bailey, of Louisville, thought phenacetine the safest remedy to give so far as the heart is concerned; but if he apprehends heart failure, instead of giving strychnia, he gives caffein.

Dr. E. P. Easley, of New Albany, Indiana, was surprised to find that antikamnia had so many friends, as he thought it was a therapeutical outlaw. He reported the case of a young lady, 22 years of age, weight 165 pounds, in robust health, where, by mistake, 24 grains of antikamnia were given for an ordinary headache with fatal result. He was firmly convinced that all antipyretic remedies should be prescribed with great care.

Dr. Dudley S. Reynolds, of Louisville, remarked in regard to dosage, that in an acute attack of iritis or cyclitis in a patient able to go about, or who had no heart complication, one or two grains of phenacetine every hour would in about

twenty-four hours dissipate all manifestations of the inflammation in many instances. Of course, it was not always uniformly successful. He believes that small doses frequently administered will bring about the desired effect with more certainty and uniformity and with less danger to the heart.

Dr. William Cheatham, of Louisville, read a paper entitled

THE EFFECT OF DISEASES OF THE EAR UPON THE GENERAL CONDITION (see p. 256).

Dr. F. C. Heath, of Indianapolis, Indiana, read a paper entitled

PRACTICAL SUGGESTIONS TO THE GENERAL PRACTITIONER IN EAR TROUBLES.

The purpose of the paper was to give a few suggestions in the management of ear troubles necessarily treated by the general practitioner, such as foreign bodies in the ear, earaches and purulent discharges from the ear.

The foreign bodies most likely to be found in the ear are, in adults, forgotten masses of cotton and various insects; in children, pebbles, beads; corn, beans, and other articles put in the ear by the little patients themselves or their companions. Such cases are very likely to fall into the hands of the family physician. What is he to do with them? The most useful and effective instruments for the removal of these bodies is the syringe. Warm water should be used, and it should be gently injected. By this simple means the majority of foreign bodies may be quickly and safely removed from the external auditory canal. An effort should be made to direct the water to one side of the object that we may get on its return a *vis a tergo*. Otherwise the force of the water may carry the body farther into the canal. This danger is still greater in case of objects so large as to fill the lumen of the meatus. Straightening the canal by pulling the auricle a little upward, outward and backward will facilitate matters. Beans, corn and other articles likely to swell from contact with water should either be removed altogether with instruments (hooks, scoops, and forceps), or, if the syringe is used without success, there should be no delay in resorting to instruments. Insects may often be killed by solutions of chlorinated soda or choloform previous to removal with syringe, if the hook-like appendages of larvæ becomes so attached to the tissues that syringing fails they may be picked out with forceps. While foreign bodies may cause trouble by exciting pain or inflammation, this is far less common and less serious than that produced by injudicious and unsuccessful efforts at removal. Destruction of the drum-membrane, injury to the ossicles, loss of hearing, facial paralysis, and even death resulted in these cases. It behooves the surgeon, therefore, to see what he is doing and proceed with care. The canal must be well illuminated and instruments manipulated in such a way that objects may not be pushed, or allowed to slip further in. If unable to come up to these requirements and where the syringe fails, the good of the patient as well as the reputation of the physician and of the general profession require the transfer of the case to more competent hands.

Accumulations of hardened wax may be removed usually according to the rules already laid down, but some cases will require the previous use of an alkaline solution or other means for softening the mass.

A more frequent trouble in the practice of the family doctor is earache, often very severe. This may be neuralgia from the teeth or other causes, in which case removal of the cause and anti-neuralgic treatment are indicated. But far more commonly it is due either to acute inflammation of the middle ear or furuncle of the external auditory canal. The greater pain, tinnitus, and impairment of the hearing in the former affection will aid in differentiating—also inspection of the canal and drum head. It a fatal mistake to regard the earaches of children as trifling—so many of them are attacks of acute inflammation of the middle ear, resulting in more or less impairment of hearing, and in some cases, of course, still more serious affections follow both in children and adults. The remedies used for these troubles are numerous and various. Some of the most disgusting are skunk oil and human urine. The means most effective both in furuncle and otitis media are heat and blood-letting. Heat may be applied in various ways—blowing in the warm breath, or dropping in hot water with a medicine dropper, answer well in many cases. A hot water bag placed against the auricle is very efficient; a simple substitute is a hot water bottle wrapped in a towel or napkin against which the ear may

be laid. But perhaps the best method in middle ear inflammation is douching the ear with hot water from a fountain syringe for ten or fifteen minutes at a time as required for the relief of pain. This should not be overdone on account of the macerating tendency on the drum-membrane, and the liability in furuncle to produce diffuse inflammation.

When hot applications fail, blood-letting should be resorted to. One or more leeches should be applied to the tragus (in front of the ear,) not to the mastoid unless that is diseased. They give great relief in middle ear troubles, but often fail in furuncle. The latter trouble may be relieved by painting with tincture of iodine or a 20 per cent. solution of menthol in benzoinol. We may incise, or preferably puncture, early in the case, with less pain to patient after the formation of pus. In either affection morphia and atropia solutions may be used, although not very reliable as a rule, nor so effective as the measures already suggested.

Purulent discharges from the ear trouble the general practitioner as well as the specialist. The origin of this discharge is sometimes in the external canal, but far more often in the middle ear. The doctrine that we should not meddle with the ear, that the discharge is salutary and not to be checked, is a pernicious one held not only by the laity, but also by some of the profession. The fact is these discharges are often serious—caries of bone, meningitis, cerebral abscess, pyæmia and death are among the possible sequelæ. Pyoktanin is said to be effective in this affection. In using this, as well as silver solutions, care is necessary to avoid staining the clothes or person of the patient. Peroxide of hydrogen is contra-indicated in acute troubles of the ear, but very successful in chronic discharges. Although it is often used in full strength, the essayist prefers to dilute it, having seen it on one occasion produce severe inflammation.

But the question may occur to some practitioner, "shall I use the Politzer air-bag or other means of inflating the middle ear in these cases of earache and purulent discharges?" Many a routinist thinks of this as a remedy for all ear troubles just as he does of digitalis for the heart and atropia for the eye. Inflation is indeed valuable in many of these cases, but it should be used with care and moderation. In purulent affections it is an aid in cleaning out the ear and in earaches from acute (or subacute) otitis media it may be found of service. Inflation should be made gently and tentatively at first (if at all) in the acute stages of these troubles lest they be rendered worse instead of better. But often by opening up the eustachian tube, dislodging pus, mucus or serum, restoring the memorana tympani to its normal position and equalizing the air pressure on both sides of the membrane, pain is relieved and inflammatory products are absorbed. This may be accomplished either by the Politzer or the Valsalva method, the latter consisting in puffing out the cheeks forcibly with nostrils and mouth closed. Sometimes the reverse is of benefit, swallowing with mouth and nostrils closed, thus causing a partial evacuation of the contents of the middle ear, air, serum, mucus or pus.

These suggestions are offered not as an exhaustive or technical discussion of the subject, but in the hope that they may not be entirely without practical value to the general practitioner in treating the common forms of ear troubles coming under his charge.

Dr. L. C. Cline said that ear cough, referred to by the essayist (Dr. Cheatham), was frequently overlooked by the general practitioner, who treated cases for months without benefit, thinking the trouble was in the throat or bronchial tubes. He reported the case of a school teacher, who had been treated for nine weeks without benefit. Her cough was so bad that she could not sleep until after 12 P. M., without some anodyne to relieve it. Examining the ear he found it impacted with wax and suppurating. He touched the ball of wax with his probe and the patient screamed. The cough he thought was due to the wax in the ear as its removal was followed by relief of all the symptoms. He had seen other cases.

Dr. S. E. Munford, of Princeton, Indiana, mentioned a case of chronic suppuration of the ear in which he cleansed the ear with peroxide of hydrogen. About a week thereafter he had to chisel open the mastoid cells. He believed that the peroxide forced purulent matter into tne mastoid cells.

Dr. Dudley S. Reynolds said, that while the syringe was useful in removing foreign bodies and accumulations of pus

from the ear, it was, at the same time, attended with danger, and corresponding importance should be attached to subsequent inflation by the Valsalva or some other method.

Dr. S. H. Charleton said, in the few cases of suppuration of the middle ear that had come under his observation, he had perforated the drum and evacuated the pus early, the patients doing well. He had seen bad effects in some cases from negligence, but never saw a person die from suppuration of the mastoid.

Dr. C. W. Murphy asked Dr. Heath in what form he used boric acid, whether in powder form or solution.

Dr. Heath replied that he used it in powder form in the chronic cases. In the acute cases, if the suppuration did not yield quickly to cleansing measures, he would resort to it as in the chronic form.

The papers were further discussed by Drs. Yost, Cheatham, Reynolds, Cline, Ball, and Bailey.

Dr. L. C. Cline, of Indianapolis, then read a paper entitled: THE EFFECTS OF INTRA-NASAL OBSTRUCTIONS ON THE GENERAL HEALTH. (see p. 259.)

Discussed by Drs. Cheatham, Charleton, and Cline.

Dr. E. P. Easley, of New Albany, Indiana, followed with a paper entitled HYPNOTICS. (see p. 262.)

EVENING SESSION.

The Society was called to order by President Elder at 8 P. M. Dr. Dudley S. Reynolds, of Louisville, took the chair and Dr. Elder delivered the President's Address.

He said that one of the most important considerations in connection with the meetings of the Society was to make them practical. The prime object should be to give the greatest amount of practical information, so that every member will learn something that he can at once utilize in his every-day work. Dr. Elder then presented some thoughts relative to recent studies and teachings in medical science during the last year.

The past year has witnessed marked growth in many departments and a definite solution of many problematical questions.

One year ago he presented to the Society a paper defining recent views regarding pyrexia, hyperpyrexia and fever; that while animal heat was considered to be the result of metabolisms, yet it was directly influenced and controlled by the nervous system, and that the thermogenic function of the nervous system was one of its most important. This thermogenic function consists of three factors, viz., heat production (thermogenesis), heat radiation and loss (thermolysis), and heat regulation or thermotaxis; that a disturbance of either of those functions produced pyrexia or hyperpyrexia. And further that these thermic disturbances alone were not fever, but that fever came on in connection with pathological conditions other than these variations of temperature. Those views have passed into the domain of accepted verities. We know that the mere presence of abnormal heat is not the measure of the pathological process. We may have an exceedingly high temperature from retarded thermolysis, heat production being small but its escape retarded and a high temperature results. On the other hand, heat production may be enormous and its radiation equally rapid, consequently a high temperature does not ensue, yet our patient is most dangerously sick.

The most important advance in medicine during the last twelve months has been in the department of bacteriology. This vast field now yields fruits which are rapidly controverting old opinions and establishing on logical and firm foundations a new ætiology, pathology and therapeutics.

Dr. Elder then laid before the Society the very latest precise knowledge on the subject of bacteriology, as set forth only a short time since by Dr. Geo. M. Sternberg, of Washington, after which he passed to the examination of a few more pathological conditions in the most advanced light of modern research. He called particular attention to erysipelas and diphtheria. Erysipelas has always been the source of controversy, its ætiology and therapeutics were unsettled and unsatisfactory. Recent pathologists place it among the contagious, infective, specific diseases. That it is a disease of microbic origin seems incontestable. The contagiousness of erysipelas has been recognized for centuries, and on this account early attempts were made to include it among microbic diseases. The speaker touched upon the discovery of the streptococcus of erysipelas by Fehleiasen in 1883, gave a description

of it, and then dwelt at length upon inoculation experiments, the manner of infection, and the relation of erysipelas to phlegemonous inflammation and suppuration.

Viewing erysipelas as a microbic disease the treatment resolves itself into two prominent indications: (1) The destruction of the specific micro-organisms and prevention of its extension; and (2) the protection of the patient from ptomainic infection and from the invasion of putrefactive bacteria, and the general treatment to relieve the ordinary phenomena of inflammatory diseases, pain, fever and functional disturbances of the various organs. As remedies to destroy the specific microbe and to protect against the invasion of putrefactive bacteria, the remedy *par excellence* is bichloride of mercury. Layers of cotton wool saturated with a warm solution of bicloride of mercury 1-3000 to 1-5000, applied over the inflamed surface and covered with oil silk is the ideal local remedy. The speaker urged this treatment in lieu of all the various poultices, washes, paintings, coverings or other applications so freely and indiscriminately recommended without any definite conception of their utility.

To fulfill the second class of indications, viz., to protect against ptomainic infection either from the specific germ, or that of putrefaction, and from the effects of functional disturbance of the various organs, there is nothing better than these remedies which experience has so positively proven beneficial, viz., iron, quinine, and supporting measures. These should be given freely and constantly. Opium to relieve pain, antipyretics to control fever, digitalis and strychnia to sustain the heart, cholagogue cathartics to secure excrementitial hepatic function, diuretics if needed to assist the kidneys in eliminating effete matter, stimulants and supporting measures, are all indicated, as a matter of course, in this as in all maladies of a febrile nature. His plea is especially for the antiseptic local treatment, earnestly and intelligently applied, thereby saving much constitutional disturbance, thus avoiding the necessity of much systemic medication.

Passing to diphtheria we enter a most interesting field. Its history dates back to the times of antiquity. Nothing in the history of medicine has more clearly shown the progress towards an exact science than the study of this subject. There can no longer be any differences as to the disease being primarily a local or a constitutional one. It has been clearly proven beyond a question that a rod-shaped bacillus, first discovered by Klebs, alighting upon a susceptible mucous membrane, produces the characteristic local lesions. It has also been proven with equal certainty that the bacilli found in the diphtheritic exudate produce a chemical poision, and it is this that induces the constitutional symptoms.

Histological changes. We owe largely to the labors of Wagner, Weigert, and more particularly to the splendid work of Œrtel, our knowledge of the minute changes which take place in diphtheria. According to Œertel "The diphtheria poison induces first a necrosis or death of cells with which it comes in contact, particularly the superficial epithelium and the leucocytes. The deeper cells of the mucosa and of the other parts reached by the poison may be affected. The second change is a hyaline transformation of the dead cells, or as Weigert terms it, the production of coagulation necrosis. The bacilli excite inflammation with the migration of the leucocytes, which are destroyed by the poison and undergo the hyaline change. The superficial epithelial layers undergo a similar alteration, and when we know as the *false membrane*, represents an aggregation of dead cells, most of which have undergone the transformation into hyaline material. This is in all probability a conservative process, by which, in a measure, the poison is localized and prevented from reaching the deeper structures. The laminated condition of the exudate is probably produced by the inflammation of different layers. The formation of these foci of necrobiosis, starting from the epithelium and proceeding inward, is, according to Œrtel. the distinguishing characteristic of diphtheria. The action of the poison is by no means confined to the superficial mucosa on which the bacilli grow. Although they do not themselves penetrate deeply the contiguous bronchial glands show extensive foci of necrosis. In severe cases these necrotic areas are found in the internal organs, in the solitary glands of the intestines, and in the mesenteric glands."

The treatment of diphtheria consists of

three factors: 1, prophylaxis; 2, general treatment, and 3, local treatment. Cases of diphtheria should always be isolated. Clothing, utensils, play things, books, and other articles having been in contact with them should be carefully disinfected. Boiling, fumigation with sulphur, soaking and washing in the bichloride solution are the measures to be depended on as prophylactic agents. Persons liable to exposure should use antiseptic mouth washes, etc. The two prime indications in the general treatment of diphtheria are first to prevent or limit the local develment of the specific bacilli, and second to combat the effects ef the toxic materials which they produce. The most important factor in controlling the disease is the local treatment. Antiseptic washes, douches, sprays, and gargles are invaluable. Bichloride of mercury is the remedy *par excellence*, one to three or five thousand, used freely, often and assiduously offers us the most hope. Have patients to gargle every half hour bringing the fluid in contact with all the inflamed area and pseudo-membrane. A most important part of the treatment is to bring the medicine in contact with the specific bacilli. Frequently this can only be done by dissolving the false membrane. For that purpose, applications of lactic acid and lime water, vegetable pepsin (paypayotin) and trypsin. Lactic acid and lime water, two drachms to 6 ounces, and trypsin and water, 30 grains to one ounce. These are the speaker's favorites.

Dr. U. H. Hon, of Bloomington, Indiana, followed with an address entitled "The Outlook of Life To-Day." It was instructive and interesting.

Second Day—Morning Session.

The Society was called to order at 10 A. M. by the President.

Dr. Joseph M. Mathews, of Louisville, read a paper on

"How To Deal With Fistula In Ano."

He had once heard the elder Allingham remark that in his opinion "it required more surgical knowledge and dexterity to operate on and cure a complicated case of fistula in ano than any other surgical affection." The more Dr. Mathews met with this very troublesome disease the more he was persuaded of the truth of Allingham's assertion. Too little attention was given by authors of books to the details of the operation. He knew that the elastic ligature had strong advocates in Dittell, Allingham, and others, but the procedure seemed so unsurgical and withal so unsatisfactory, that but few surgeons had given the plan much endorsement. The more he used the elastic ligature in the treatment of fistula in ano, the less he liked it. When compared with the knife in operating for fistula, all other methods must suffer by the contrast. What can be accomplished by the knife in a few minutes, it took days or weeks for the other plans of treatment to do. Edges of wounds can be trimmed, additional sinuses sought for and divided, the bottom of all cut through, antiseptic surgery practiced, and a perfect cure effected, when the knife is used.

Dr. Dudley S. Reynolds, of Louisville, followed with some remarks on "Abscess in the Attic of the Ear."

Dr. S. E. Munford, of Princeton, Indiana, read a paper entitled "A few Notable Remedies." (See p. 261.)

Dr. Allen Pierson, of Spencer, Indiana, read a paper on the Treatment of Varicocele. He referred to the recent monograph of Dr. G. Frank Lydston, of Chicago, in which some thirty or more operations were mentioned for the radical treatment of varicocele, nearly all of which were named after the operator who had been the chief promulgator of some particular phase of the operation. Nearly all of these methods seek to obliterate the diseased veins. The object of some was to make a suspender of the scrotal tissues and by relieving the tension of the dilated veins give them the opportunity to recover their normal tone. These might be properly classed among the palliative methods.

Leaving out of consideration those methods in which caustics, remedies to coagulate the blood in the veins and electrolysis are the agents employed to secure obliteration, the other purely radical methods seek to obliterate the veins (1) by subcutaneous deligation, (2) by open deligation, and (3) by open deligation with excision of a portion of the diseased veins. A clear understanding of what is to be done and the simplest and safest manner of doing it were necessities, especially to one whose practice was private,—away from the hospitals or public institutions of any kind,—in the homes of the people. The dread of operations on varices no

doubt arose, in part, from the results in such methods as Vidal's or Ricord's

With simplicity and safety in view we avoid making extensive incisions in a location where they become peculiarly a source of danger unless there existed some abnormality. In the normal arrangement of the veins and in subjects where there are no calcareous deposits in this location there ought to be no difficulty in isolating the veins from the vas deferens with its attending artery; this being done subcutaneous deligation ought to be as easily accomplished as ligation in the open method. The speaker then went over the steps necessary in subcutaneous deligation, and closed by saying that the comfort of the patient, the freedom from complication, and the success of the operation depended upon cleanliness in a great measure; that in a few cases that had fallen to his lot to treat in this manner the secondary operation had been needed in none, and the operation had been ideal to all, and it was only because the tendency of the practice in these cases seemed to be in the direction of the open methods that this method was thus spoken of that it might, in some measure, be a defense for its use.

Dr. G. Frank Lydston, of Chicago, read a paper entitled "Irrigation of the Deep Urethra and Bladder Without Catheter or Tube."

From personal observation he had been led to believe that there was the greatest possible variation in resisting power of the deep urethral muscles and vesical sphincter. He had noticed that in some patients it was quite easy to force fluids into the deep urethra and bladder, while in others as much force as was compatible with the integrity of the urethral walls might be employed without forcing injected fluids into these parts. Patients had themselves informed him that it was only with great care that they were able to inject the the urethra without forcing the medicament into the bladder, while others never made such complaint. He was at first inclined to attribute this difference to roughness of manipulation, but experiments had since proven to his satisfaction, that experience of these patients involved a point of great practical interest and importance. He had for many months been using irrigation with a short urethra nozzel in the treatment of urethritis, and had therefore been able to gain some valuable experience in this direction. He found that in many patients there was little difficulty, the irrigator being about the level of the patient's head, on an average, in irrigating the prostatic urethra and bladder without either tube or catheter. This is accomplished with no discomfort to the patient as a rule. He had utilized this practical point in the treatment of posterior urethritis to great advantage. One of the advantages of this method of irrigation in prostatic troubles was the facility with which hot water might be applied directly to the prostatic sinus. By carefully adjusting pressure by means of the fingers, about the nozzel while the latter is *in situ* at the meatus, the entire urethra may be kept fully distended by the solution, while the excess of water is allowed to escape around the nozzel. In the treatment of urethritis this method of irrigation was far superior to that usually adopted. A very promising feature of the method, was the fact that the patient could easily irrigate his own bladder in quite a proportion of cases, something that he could not readily do *via* the catheter. The method is designed to meet the indications existing in a large class of cases in which irrigation of the bladder and prostatic sinus is demanded, yet catheterism was to be avoided if possible. Whenever we could accomplish the purpose of vesical or urethral irrigation without instrumentation, it was our duty to do so.

The following officers were elected:

President.—Dr. Dudley S. Reynolds, Louisville, Ky.

Vice-President.—Dr. C. W. Murphy, Salem, Ind.

Secretary and Treasurer.—Dr. Geo. W. Burton, Mitchell, Ind.

Place of next meeting,—Spencer, Ind. Time, December 29, 30, and 31, 1892.

The Society, after tendering its thanks to the management of the West Baden Springs Hotel, on motion, adjourned.

ASTHMA, ESPECIALLY WHEN COMBINED WITH DIGESTIVE DISTURBANCES.

The following is recommended (*Lo Sperimentale*, No. 18, 1891):

℞
Strychniæ sulphat.....mgms. 10-20.
Pulv. ipecacuanhæ.....cgms. 30.
Piper. nigr. in pulv.....cgms. 30.
Extr. genitianæ.....gms. 1.5.
Essent. pervinca.....gtt. 1.
Sufficient for twenty pills. One after each meal.

THE

MEDICAL and SURGICAL

REPORTER.

ISSUED EVERY SATURDAY.

DIRECT COMMUNICATIONS TO

P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor.

(Professor of Physiology, University of Penna.)

BUSINESS OFFICES:

29 to 35 North Tenth Street, Cor. Filbert.

EDITORIAL OFFICE:

Southeast Cor. 36th and Woodland Ave.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00

REMITTANCES should be made payable to THE MEDICAL AND SURGICAL REPORTER, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

—o—

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates)....$1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt "**The Medical and Surgical Reporter**" and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts.....$1.50 each.
Bovine Points or Quills..... 1.00 a doz.
Humanized Crusts..... 1.00 small.
Humanized Crusts..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

VAGINAL EXTIRPATION OF THE UTERUS.

Free discussion and the publication of all results, whether good or bad, are the only means by which the profession can assure itself of the utility of any surgical or therapeutic procedure. The opinions entertained regarding the value of the operation of vaginal extirpation of the uterus and adnexa, by gynæcologists in this country, are well known to the majority of our readers. Recently, however, the subject has been actively discussed abroad, cases cited, and theories advanced. The results of these are interesting, embodying as they do opinions based upon the experience of some of the most eminent gynæcologists in Europe.

Segond, who was originally the most vehement opponent of Péan's suggested "uterine castration," but who was converted to the operation by a case of his own successfully operated upon by Péan, not long since reported to the Surgical Society of Paris the results of 23 operations performed by himself. The operation was always made in cases of suppurative processes of the tubes and ovaries.

There were four deaths—all resulting directly from the operation. Péan on the other hand, has reported 66 cases without a single death. The remaining 19 cases of Segond's completely recovered. Segond regards any disease of the tubes and ovaries which would require laparotomy as an indication for the vaginal extirpation of these parts. The chief advantages claimed by the upholders of the operation are, the absence of an abdominal scar and the impossibility of an abdominal hernia as a result of the operation.

Bouilly, another French writer, while never having performed Péan's operation, nevertheless expresses himself as being strongly opposed to it except in such cases where firm adhesions to the neighboring

parts and the presence of old fistulæ render the result of a laparotomy doubtful. He claims that in the vast majority of cases of disease of the ovaries and tubes laparotomy and not Péan's operation is indicated. Bouilly considers Segond's claims for the merits of the operation unfounded; that the number of cases as yet reported is not large enough to permit of any definite conclusion being reached; and that Segond's rate of mortality is certainly against rather than for the procedure.

Richelot also suggests that Segond's enthusiasm has carried him too far. While Richelot does not deny the superiority of Péan's operation in certain peculiarly adapted cases, yet he believes that the operation should never be attempted as a substitute for laparotomy unless specially indicated.

Bazy recognizes only two indications for the operation: First, a suppurative condition of both adnexa coupled with a poor general condition of the subject; Second, old lesions of the adnexa which deprive the latter of their functions. Even the last indication is, according to Bazy, open to objection, since the possibility of a restoration of the normal functions of the ovaries and tubes can only be determined by a laparotomy.

Terrillon, whose numerous writings on gynæcological subjects are well known to our readers, states that in his opinion Péan's operation has decided advantages over laparotomy in cases of suppuration of the ovaries and tubes complicated with intestinal adhesions. He has performed four such operations, all of which resulted favorably; in conclusion, he states that the operation is, however, rarely indicated, and should not be undertaken in the general run of cases as a substitute for laparotomy.

Pozzi, the Italian gynæcologist whose experience with laparotomy has been so extensive, is decidedly against the operation. He bases the reasons for this opposition on the following grounds: First, because the operation does not give better results than laparotomy, and because in laparotomy the diseased organ can be directly removed, while in Péan's operation it must frequently be left behind. Second, because the latter is equally severe an operation as laparotomy, and while in the former a possible mistake in the diagnosis cannot be controlled, it can be in laparotomy. Third, because the cosmetic advantages should not be taken into consideration at all.

Routier, in an article on the subject, while not speaking from personal experience, states that the good results he has had from laparotomies do not permit him to abandon it for any other method as yet offered.

Lucas Championiere, on the contrary, is convinced that in all cases where the suppuration if not confined to the ovaries and tubes, but has invaded the neighboring tissues, Péan's operation is undoubtedly indicated, and promises the best results. This opinion is, however, based upon theory only, since he has not met with a case in which he could apply the operation, and he acknowledges that the excellent results obtained by laparotomy would not justify its abandonment. He also calls attention to the difficulty experienced in diagnosing suitable cases.

Terrier claims that the operation should only be attempted when the case is one of pyosalpinx complicated with suppuration of the pelvis, and Reynier confirms this opinion.

We may also quote the results obtained by Segond in operations of total hysterectomy for cancer of the uterus, which he has recently published in the *Semaine Médicale*. In all he has operated upon thirty-three cases, twenty-five consisting of cancer of the cervix and eight of cancer of the body of the womb. His results were twenty-six recoveries and seven deaths. The causes of death were septicæmia, peritonitis, strangulation of the intestine,

hæmorrhage, and shock each one case; and two cases from subsequent peritonitis. Of those which recovered from the operation three had a return of the disease in three months; eight are alive but have not been examined; three seem completely cured, the operation having been performed in 1888 and there having been no sign of a return of the disease. The others have been lost sight of.

In conclusion, it may be justly claimed in view of the opinions of those foremost among European gynæcologists that in Péan's operation of vaginal extirpation of the uterus, ovaries and tubes, we have a surgical procedure which should only be undertaken under certain specified and rare circumstances, and that the asserted superiority Péan's operation over laparotomy cannot be supported by the meagre experience yet obtained.

THE OPERATIVE TREATMENT OF RETRO-DISPLACEMENT OF THE UTERUS.

Chaput (*Semaine Mèdicale,* 1892, No. 17), at the conclusion of a paper on this subject, summarizes as follows: 1. Simple retroflexion requires no treatment. 2. Retroflexion complicated with metritis and prolapsus is best treated by curetting and repair of the pelvic floor. 3. Alexander's operation is often difficult, and sometimes fails to keep the uterus in its normal position, or if the organ is anteverted the symptoms are not relieved. 4. Ventrofixation is preferable to the latter operation, since the surgeon is not only sure that he has replaced the uterus, but he not able to remove the adnexa, which are so frequently diseased.

Saenger (*Centralblatt für Gynäkologie*, 1892, No. 1) continues his controversy with Schücking relative to the operation devised by the latter, which he opposes on the ground that fixation of the anteflexed uterus is not the result to be aimed at in ventro-fixation, but rather shortening of the sacro-uterine ligaments with free mobility of the organ, as when it is supported by a pessary.—*Amer. Jour. Med. Sci.*

Book Reviews.

THE DIAGNOSIS OF DISEASES OF THE NERVOUS SYSTEM. A Manual for Students and Practitioners. By Christian Herter, M. D. Physician to the Class of Nervous Diseases, Presbyterian Hospital Dispensary, New York. New York and London: G. P. Putnam's Sons, 1892.

This book possesses originality in its arrangement which commends it, and the facts concerned in the diagnosis of nervous diseases are related in a fresh manner. It is given to the profession with the understanding that it is an elementary treatise, yet the text is full enough to make it serviceable to all physicians. The chief good points about the work are its system and practical bearings. Instead of a complete elucidation of the anatomy and physiology of the nervous system, only the important facts concerned in a thorough understanding of the sensory and motor pathways have been detailed, and credit must be accorded the author for the excellent way in which this has been done, and for the very comprehensive diagrams with which the text is interspersed in this portion of the book.

The second chapter, upon the symptomatology of nervous diseases, gives a description of symptoms with reference to their diagnostic and pathological significance. In this way the student learns the true value of symptoms, and this is more by their association in groups than by their individual worth.

In the third chapter, which is upon the localization of lesions, the author has given the important symptom-groups in connection with each lesion. Thus it will readily be seen that symptomatology has received special attention, being discussed from the standpoints of general symptomatology and in a special way as related to the pathology of nervous affections.

The fourth chapter is devoted to the nature of the lesion, and all the ætiological, symptomalogical and pathological facts have been gathered together in order to throw as much light as our present knowledge of the subject will permit. The facts which are learned from the diagnosis of the position of the lesion are also brought together, and play by no means an unimportant part in certain diagnoses.

Following this is a chapter upon clinical types of nervous diseases. The types are

clearly represented, and the claim of the author that "variations in type" and "transitional forms" have been duly recognized, must be allowed.

The next chapter is probably the most interesting of the book, and deals with the diagnosis between organic and functional disease. The book ends with a short chapter upon the examination of patients.

Taken as a whole, we think that the book will be chiefly of interest to those who desire to be specially familiar with nervous affections. It is a good student's book, and will be found very useful to the general practitioner.

VARICOCELE AND ITS TREATMENT. By G. Frank Lydston, M. D. Chicago: W. T. Keener, 1892.

In this monograph the author has given us a review of the subject of varicocele and its treatment in a concise yet comprehensive manner. The contents comprise eight chapters and eighteen illustrations. The text is written in a most agreeable style, which characterizes the author's articles.

The treatment of the milder forms of varicocele is, according to Dr. Lydston, altogether palliative. He states that in a large proportion of cases all that is necessary to do is to allay the patient's mental annoyance by a little sound physiological advice. Instruction in sound physiology and hygiene is necessary in all cases in order to keep the patient out of the hands of the quack on the one side and to assist in a cure on the other. Marriage is recommended as the best remedy in cases which the author terms "spermatic congestion." Regulation of the diet and active exercise is strongly recommended, as are cold flagellations and the use of a suspensory bandage as adjuncts to palliative treatment. The cure of this condition by coagulative electrolysis and caustics also receives thorough attention. Finally, the various operations which have been devised of late years are fully detailed. The book is a valuable addition to genito-urinary surgery.

THERAPEUTICS.

ACTION OF TUBERCULIN IN RABBITS.

Prof. Doenitz, of Berlin, published in November (*Amer. Jour. of Ophthalmology*) the results of experiments in regard to the action of tuberculin upon the experimental eye tuberculosis of the rabbit. The conclusions are:

1. The tuberculin is a sure curative agent for the experimental tuberculosis of the eye of the rabbit.
2. The tuberculin shows its curative effect only after the tubercle can be demonstrated.
3. The first effect of the tuberculin is a transient, but severe irritation of the eye.
4. Under the continuous action of the tuberculin, all irritation of the eye subsides.
5. When, before beginning the treatment, deep-reaching destructive processes have not occurred, the cure results in retention of the visual functions of the eye, otherwise atrophy results.

TREATMENT OF PLEURITIC EFFUSIONS.

Köster (*Therap. Monatsh.*, March, 1892) says that the use of the salicylates in the treatment of serous pleuritic effusions has not become so general as it deserves to be. He has thus treated 32 cases, 27 of which were examples of the primary disease, while 5 were secondary to tubercle, as shown by the physical signs or character of the fluid. In 17 out of the 27 cases the results were very favorable. These cases not only included small as well as recent effusions, but also large ones and those in which the patient had suffered from symptoms for weeks. The results, however, were most favorable in recent cases. In most patients there was moderate fever, which declined rapidly. Absorption began almost as soon as the treatment, and in from five to seven days even large effusions had disappeared. Once or twice the abnormal physical signs did not clear up for some time. The amount of urine was quickly increased. The symptoms of which the patient complained soon disappeared. In 10 out of the 27 cases the results did not differ from those obtained by other methods of treatment, and

3 of these had to be tapped. The probability of the tuberculous nature of these cases must be borne in mind, but here there was no evidence in favor of it. Among the cases of apparently secondary pleurisy, the results were occasionally also decidedly good.—*Brit. Med. Jour.*

MEDICINE.

PARACENTESIS PERICARDII IN GRAVES' DISEASE.

Shattuck (*Boston Med. and Surg. Jour.*, November 5th, 1891) records this case. The patient, a young woman, aged 24, suffered from rheumatic symptoms and pericarditis. The pericardial effusion rapidly increased, so that on the eighth day the area of cardiac dullness extended from well outside the left nipple nearly to the right nipple and up to the second rib. Aspiration was decided upon, so a trocar was introduced into the fifth left interspace three inches from the median line; about one ounce of bloody serous fluid was removed. As no more could be obtained from this situation, though the cannula was freely movable, another puncture was made in the fourth right space two and a-half inches from the middle line, but no fluid was obtained. An ice bag was applied to the heart, and next day pericardial friction was heard. Two days later, as she was worse, another puncture was made on the left side, but only half an ounce of blood-stained serum was withdrawn, and two days later another puncture on this side, but further out, failed to remove any fluid. After this the patient did well, and eventually recovered. During convalescence it was discovered that she was the subject of Graves' disease, but without exophthalmos, and it was surmised that this disease had been existent all along.—*Brit. Med. Jour.*

HIGH TEMPERATURE IN INTERMITTENT FEVER.

Dr. Stephen Mackenzie, in the *British Medical Journal* for February 13th, reports a case of intermittent fever in which twice the temperature was 107° F., twice 113°, and once 113-8°. The observations were made with the thermometer in one or the other axilla; sometimes two thermometers were placed in the axilla at one time and found to correspond. On account of rigors the temperature could not be taken in the mouth. The periods of hyperpyrexia were exceedingly brief, sometimes a return to normal temperature occurring in five minutes. The patient recovered.

SURGERY.

OPERATIVE TREATMENT OF GLAUCOMA.

Collins (*R. L. Oph. Hosp. Reports*, Dec., 1891,) gives some interesting conclusions based upon the pathological examination of twenty-three eyeballs which had been operated upon for glaucoma, chiefly by iridectomy. Assuming that the tension in primary glaucoma, however it may arise, is kept up by the apposition of the root of the iris to the posterior surface of the cornea and a consequent blocking of the filtration angle, Collins infers that an iridectomy may remedy the condition in either of three ways:

1. When the apposition is recent, very slight means may suffice for the escape of the aqueous, a drag on the iris being often enough to loosen the attachment.

2. In recent or acute cases the iris may tear away from its extreme root, thus leaving a portion of the filtration area free for drainage, even should the remainder of the iris keep its faulty position.

3. In other cases a permanent gap is maintained in the walls of the globe by the prolapse of a fold of iris into the wound. Subsequent stretching or atrophy of the iris tissue occurs, or periodic rupture of the same, thus allowing the aqueous to pass through into the subjunctival tissue and thus become absorbed.

A sclerotomy may produce a permanent reduction of tension in either the first or last of these ways, or it may open up a fresh means of access to the filtration area, so that excess of fluid could find a direct channel of exit from the posterior channel. It is unlikely that the fibrous tissue of a cicatrix should more easily allow filtration through it than the ordinary tissue of sclera or cornea. Iridectomy or sclerotomy will fail to relieve tension when none of the above results are attained. An iridectomy may also fail in consequence of displacement forward of the lens, so that its upper part blocks the freshly-opened filtration area, adhesions resulting between

it and the sclero-corneal cicatrix. The practical lesson is the advisability of an early iridectomy before the apposition of the root of the iris has resulted in adhesion, or a preventive iridectomy might be done, as in the majority of cases primary glaucoma affects both eyes. Iridectomy is most likely to succeed where there is least adhesion of iris root and cornea.

OBSTETRICS.

PREGNANCY AND VENTRO-FIXATION.

Fraipont (*Annal. de la Soc. Méd.-chir. de Liège*, 1892, No 4) reports seven cases of ventro-fixation by Winiwarter and himself, three of the patients who were married, becoming pregnant soon after operation, although one of these had a small ovarian cyst and two a cystic ovary. In each instance the diseased ovary was removed and the fundus uteri was attached by deep sutures including the edges of the abdominal wound. One woman was delivered at term, another at seven and one-half months, in consequence of an accident, the child living; the third bore a living child at the eighth month. All the patients complained of severe pains in the cicatrix between the third and fourth months of pregnancy, which were absent in the latter half. Labor was normal in each instance. In one case only the uterus was found to be retroverted after delivery. It is doubtless desirable that pregnancy should not occur so soon after the operation, since the adhesion is at first quite firm, but later becomes more cord-like and distensible, allowing the uterus to rise out of the pelvis, while preserving its normal position.—*Amer. Jour. Med. Sci.*

AN UNUSUAL CASE OF TWINS.

O'Reilly (*Archives of Gynæcology, Obstetrics and Pediatrics*, April, 1892), describes an interesting case of dual pregnancy. The patient, a IV-para, in labor at term, had not felt the movements of her child for ten days. She was delivered of an eight months' macerated fœtus. On attempting delivery by expression O'Reilly noticed that the uterus was larger than usual after delivery and of irregular contour. By vaginal examination nothing abnormal could be detected. Ergot was administered, the pains soon became stronger, another child presented and was delivered living. The mother made a good recovery. There was but one placenta. The cords were attached within a short distance of each other. The placenta for two-thirds of its extent was of a livid red color and firm consistence. To this was attached the cord of the dead child. The other third was separated by a distinct line of demarkation and healthy. The children were not weighed immediately after birth. The living child weighed three pounds one ounce twenty-one days after delivery. The dead child's estimated weight was between four and five pounds. —*Univ. Med. Mag.*

GYNECOLOGY.

THE INFLUENCE OF PELVIC DISEASES ON THE VOICE.

Klein (*Journ. Am. Med. Assoc.*, 1892, No. 16) says that during menstruation women are prone to inflammation of the tonsils and larynx, and that he has observed in singers at this time that the voice often becomes hoarse and deep, assuming a masculine tone, so that one who is accustomed to noting the difference can tell when they are menstruating.

In many cases of ovarian disease he has observed hypertrophy of the tonsils and uvula; as in eunuchs, there appears to be an intimate relation between the voice and the sexual organs.—*Amer. Journ. Med. Sci.*

EXPLORATORY INCISIONS THROUGH VAGINA.

Segond (*Ann. de Gynèc.*, March, 1892) attended a woman, aged 35, whom he believed to be suffering from retroversion, with fibroma of the fundus. Reduction was easy. He made an exploratory incision through the vagina, and found that the tumor was not a fibroma, but an extra-uterine fœtal sac in the right tube. As the opposite tube was diseased Segond removed it, together with the sac and the uterus. A vaginal incision is not, in his opinion, inconvenient should diagnosis prove incorrect. On one occasion he diagnosed a uterine fibroid, made a vaginal incision, and found that the growth was an ovarian cyst; the tumor was removed with ease. In a second case he suspected pelvic abscess; he opened not a pus sac but a

hæmatocele. This was washed and drained, and the patient recovered with perfect internal organs. In a third pelvic fibroma was diagnosed. On vaginal incision he found a mass of proliferous ovarian tumors, and removed them, together with the uterus through the vagina. The tumor had been treated by electricity for eighteen months. When a large swelling projects downwards, pushing the vagina in front of it, the operation should be done through the vagina.—*Brit. Med. Jour.*

PEDIATRICS.

GONORRHŒAL RHEUMATISM IN THE INFANT.

Dr. Beclère has just called attention, in the *Revue dè Gènéral de Clinique et de Thérapeutique*, to a complication of gonorrhœa little known about till now, gonorrhœal rheumatism in youthful age. In less than a year he has observed two cases, one in a little girl of five and a-half years, the other in a still younger subject, a baby of twenty months. In the first of these little patients the origin of the contagion could be definitely established; the child had been the victim of an apprentice of sixteen or seventeen years of age, who had a gonorrhœa of some standing. The child was treated by immobilization and compression with cotton, and was cured in fifteen days of its arthritis, but it preserved for some time a certain amount of muscular atrophy of the whole left upper extremity (arthritis located in the left wrist), which gave way to continuous currents; the vulvo-vaginitis disappeared after lotions and injections of bichloride. Thus, in the first case, nothing is plainer; the child was contaminated by a subject of the disease, had a blenorrhagia of which the origin was known, followed by a rheumatism of the wrist. It was not the same in the author's second case; here there was a twenty months' old infant presenting the right tibio-tarsal articulation in a swollen, rosy, painful condition, together with a thick, purulent vaginal discharge and a drop of pus exuding from the meatus-urinarius. It was impossible to get precise data concerning the origin of this running, but the aunt of the infant acknowledged that the little girl slept with her mother, who had for several months suffered from a greenish vaginal discharge. The mother could not be examined. The author thinks that in this case we have to deal with a gonorrhœa-insontium accidentally transmitted by the mother to the daughter. These cases, we repeat, should call the attention of practitioners to the fact that, when they observe in infants of a tender age articular manifestations having the clinical aspect of gonorrhœal rheumatism, age does not constitute a sufficient argument to make us reject the diagnosis. On the contrary, such a case should make us think of this possibility, and cause us to make a thorough examination of the genital organs.

HYGIENE.

DOES INFLUENZA PROTECT FROM A SUBSEQUENT ATTACK?

The question whether an attack of influenza confers protection from subsequent infection is one which must have often arisen during the experiences of the last three years, but the data for its solution are not yet fully available. The amount of information which must have been gleaned by the family practitioner in all parts of the country upon this and many other points concerning the malady would, if collated, go far to settle the matter. It is of course notorious that certain individuals have suffered from more than one attack; but the conviction is pretty general that such cases really form but a small minority of the large numbers who have suffered. Then, again, it must be deemed possibly that the degree and duration of the protection may depend on the severity which the primary attack exhibited, for one can hardly invoke the doctrine of attenuation of virus in the case of this disease, which shows so much variation from the ordinary course of infective disorders in general. In a highly interesting contribution upon the features of the present epidemic in Berlin, Dr. Ruhemann directs especial attention to this question of protection and affords valuable evidence of it. He aptly remarks that the more gradual evolution and persistent character of the present epidemic, as compared with the rapid and stormy course of the pandemic of 1889 to 1890, have afforded opportunity for more closely studying the character of the malady, and that it has especially enabled us to recognize more clearly its con-

tagious nature. According to him influenza has prevailed in Berlin ever since the beginning of last September, and he notes how on this occasion the stress of the outbreak had fallen to a far greater extent upon women and children and less upon men than was the case two years ago. His own practice affords proof of this, especially in the fact of the greater frequency of uncomplicated cases among women than among men. As to the question of protection, he has observed that members of families who were severely attacked two years ago have either escaped entirely at present or been only slightly affected; whilst, conversely, the most serious cases of the present time have arisen in households which the influenza spared during its earlier visitation. He notes the statement of Dr. Edw. Gray, to the effect that "many persons who escaped the epidemic of 1775 were affected by that of 1782, and many who escaped the latter were affected by the former," as showing that a century ago this question of immunity had not passed unnoticed. Dr. Ruhemann gives his experience of 55 families, numbering 193 individuals. In 1889–90 there were 64 cases of influenza among this group, whilst in the present outbreak only 40 have been attacked, and, what is of special interest, only 5 out of this number were affected (and that but slightly) two years ago, whilst of the 64 then attacked, only 4 have again become victims. Should this prove to be anything like the general experience it would go far to substantiate a fact that has hitherto been much disputed, even to the extent of declaring that one attack predisposes to another. That one individual may have several recurrences during the prevalence of a single epidemic does not, in Dr. Ruhemann's opinion, mitigate against the general doctrine of protection, since he thinks many such recurrences may be explained by lack of caution on the part of the patients against exposing themselves to fresh infection before they are restored to full health. That influenza does not protect from a second infection should reassure many persons who, having once suffered severely from it, dread a repetition of so depressing a malady, and it may be further comfort to them to learn that the more they have to suffer at first, the less likely are they to suffer at all again. If, then, influenza shares this common property of all infective diseases, it is not so remarkable that it should not apparently select the young in preference to the adult and aged, seeing that the whole community is more or less "unprotected" when it first reappears after an absence (in pandemic form) of years.—*Lancet.*

MEDICAL CHEMISTRY.

CREASOTE AND ITS ELEMENTS.

Dr. E. Main has made a laboratory study of this remedy, which has of late attracted so much attention. He established the fact that the elements of creasote were poisonous in the following order; 1, para-cresylol (least); 2, phlorol; 3, guaiacol; 4, creasote;5, creasol (most). Locally, creasol was the most irritant, guaiacol the least. For all these elements this laboratory work shows three important characteristics: 1, that they are feebly poisonous; 2, a tolerance can be established; 3, they are eliminated by the lungs. As remedies against tuberculous they can be arranged in the following order: 1 and 2, phlorol and creasol; 3, para-cresylol 4, guaiacol; 5, creasote (most powerful). It is believed that although all the elements of creasote have some value, and indeed guaiacol should be especially mentioned, yet creasote is the most active. Beechwood creasote should be preferred for its antiseptic power, for its feeble toxicity, and because of the results furnished by experimental therapeutics as well as by clinical observation.—*Bulletin Générale de Thérapeutique*, 1892, liv. 10e, p. 205.

ON THE TOXIC AND BACTERICIDE ACTION OF THE SERUM OF THE BLOOD OF THE INSANE.

D'Abundo found that the blood serum of a paranoiac (tranquil) more nearly approached that of a sane individual in its toxic power than any other. During an intercurrent period of depression the toxic action was diminished, while during an excited period it was increased. In quiet melancholia the toxic power was diminished, but prolonged agitation increased it. In quiet dementia it was found constantly lessened. In progressive paresis it increased excepting in two cases, in one of which the patient was in a condition of quiet, and in the other there was a pre-

dominance of motor symptoms. In simple mania and in maniacal exaltation the toxicity is increased. After post-epileptic attacks, and especially in conditions of stupor, it was found diminished. In pellagrous dements it was found notably diminished. In imbecility it was diminished, and in idiocy the results were discrepant. As regards the bactericide action it was found generally increased in insanity and especially in paresis and in mania. It was diminished in post-epileptic conditions and in depressive forms.—*Archivio Italiano per le Malatie Nervose,* Sept., 1891.

NEWS AND MISCELLANY.

A NEW CREMATORY FOR BERLIN.

Berlin is shortly to have a crematory, erected at the city's cost, in the Friedrichsfeld Cemetery, where bodies of the poor and unknown and of the subjects of anatomical investigation at clinics and hospitals will be reduced to ashes. The bodies from the anatomists' tables alone number about 1,000 annually. To further this practice the Berlin Society for Cremation has petitioned the Parliamentary Commission on the Civil Code that the choice between burial and burning be granted hereafter to every German citizen.

INFLUENZA AND DRUGS.

It is stated that quinine, which in 1878 was selling at 16s. per ounce, is now selling at 10½d. The price of eucalyptus oil has suddenly doubled owing to the popular demand for it as an agreeable diffusible aromatic, vaguely supposed to have antiseptic properties when diffused in the air. To be of any use whatever—except as a mental consolation and encouragement—it would need to be used in quantities which would make the air irrespirable. Innumerable "specifics" continue to be irrationally puffed—salicin, salicylate of soda, bicarbonate of potass, antipyrine, salipyrin, and of course also hydropathy and quack remedies innumerable. It is surprising that educated men should be willing thus to enter the lists of public notoriety by recommending specific drugs for a disease which is not known to admit of any, and that they should endeavor to press upon an uninstructed public incapable of forming a correct judgment a universal use of drugs and therapeutic methods which can only be correctly used or estimated by qualified medical attendants, capable of judging the particular needs and the clinical condition of each patient. There is some loss of professional self-respect involved in such proceedings, and no good can accrue to the general public, who can but be bewildered, and are very likely to be dangerously misled by such a course.—*Brit. Med. Jour.*

AGAINST PROPRIETARY MEDICINES.

At the meeting of the Missouri State Medical Association, Dr. L. Bremer, of St. Louis, Mo., introduced the following resolutions which were unanimously adopted:

Whereas, The evil of prescribing and recommending proprietary medicines is constantly increasing, much to the detriment of the profession and the public, especially the latter, many of whom are led into the drug-habit; therefore,

Be it resolved, by the members of the Missouri State Medical Association, that we condemn the practice on the part of some physicians of giving certificates as to the efficacy or special uses and advantages of proprietary medicines, or what is usually understood by this term.

Resolved, That as a body we recommend to the profession the future discontinuance of such medicines, if now used by them.

HOT SPRINGS, THE DOCTORS, AND THE TOUTERS.

The following circular was adopted by the Hot Springs City Council, March 1892: "Don't listen to any one who volunteers advice about doctors. No regular physician will require more than $5 in advance. If you have letters to a physician, deliver them in person. If drummers find you have such letters, they will tell you the doctor is out of the city, dead, quit practising, drunk, or something of the kind. Drummers on the trains, on the streets, or at the hotels or boarding-houses will pretend that they are visitors."—*Weekly Medical Review.*

Clinical Lectures.

MELANOTIC SARCOMA; VESICAL CALCULUS; COLD ABSCESS OF HAND; FRACTURE OF FEMUR AND RUPTURE OF QUADRICEPS TENDON.

By PROF. ROSWELL PARK, M. D.,
BUFFALO GENERAL HOSPITAL, SURGICAL CLINIC.

Gentlemen:—This patient, a man of seventy, has had for seven or eight months a spot over his right nipple looking as if he had been tatooed. Underneath these little black points which you can readily see, I feel a hard mass to which the skin is attached but which still moves over the pectoral fascia. He has been on the medical side of the house and I have seen him only once before. From this history of the case, I have come to the conclusion that this is a neoplasm, and about the only tumor which can give such a black color is a melanotic one which is practically always sarcoma. It is probable, therefore, that we have to deal with a melanotic sarcoma of the skin and subcutaneous tissues. His liver is enlarged and in such a case we would expect metastasis of the liver. Were it not for this patient's age and the evil—I might say infernal—tendency which these growths manifest to recur after apparently the most perfect removal, I should advise operation. Under the circumstances, however, especially as the progress of the growth is slow, I should not advise surgical interference.

VESICAL CALCULUS.

The next patient is an old man with chronic cystitis and a very large prostate body. He suffers, as these patients usually do, with frequent urination, a certain amount of pain referred to the end of the penis and many of the rational signs of stone in the bladder. Thrice, however, a number of weeks ago, I sounded him as carefully as I could, after having injected into the bladder from a fountain syringe all the water that he could bear without an anæsthetic and I did not touch anything gritty or calcareous. Quite recently, however, the orderly who has been washing out his bladder daily informed me that on inserting a soft catheter he noticed something gritty. I also felt the same gritty obstruction to the movement of the soft catheter but I could not get the sensation with the hard catheter. I have had the patient anæsthetized in order to examine him carefully, and, if I find a stone, I shall probably make a perineal section and perform lithotomy. I should have done this sooner had it not been for the patient's age and feeble condition. Ninety-five per cent. of the cases of stone in the bladder are easily diagnosed by passing a proper sound or stone searcher into the bladder and rubbing or striking it against the stone. Occasionally, however, we meet with cases in which the detection of the stone is difficult and in which the best men fail to discover it except after the operation undertaken on account of the symptoms. Now, with the patient etherized, the minute I pass the metallic catheter I touch the stone with perfect ease. It is hard to say why I did not find it at the three previous examinations with a metallic instrument. The patient is too large and stout a man for the performance of the suprapubic operation and I do not like the method of drainage by the suprapubic operation as well as by the perineal section. After completely filling the bladder with a boric acid solution, I introduce the most approved form of stone-searcher which consists of a steel sound with a short beak in

order to verify my diagnosis. I now pass the grooved staff into the bladder and make a median section through the perineum till I reach it. On account of the fat of the patient, the distance from the perineum to the bladder is so great that only the tips of the fingers can be inserted into the bladder and I must use the forceps to grasp the stone. The stone seems partially adherent and I am hindered not only by this fact and by the unusual depth of the bladder from the surface but by the resistance offered by the enlarged lobes of the prostate. The stone slips away from the grasp of the forceps behind the prostate. In order to overcome the mechanical difficulties in removing the stone, we will extend the legs fully in order to let the stone drop back into the fundus of the bladder and to relax the perineum. I have at last succeeded in removing the stone in fragments and you are no doubt surprised that anyone, even a novice could have failed to touch it with a sound.

[Clinic four days later.]

The fragments of stone after being dried and weighed amounted to twenty-one grains. The patient left the table in good condition, the bladder drainage was free and everything was favorable till afternoon when he appeared somewhat dusky in the face, his mind was not quite clear and in the night he developed the signs and symptoms of pneumonia. The next day there was very evident pneumonia with consolidation of the lower part of the right lung. The patient ran down steadily and died three days after the operation, the bladder symptoms at no time having been alarming or sufficient to cause any apprehension. Pneumonia is not an infrequent accident of surgical practice, especially in old people and you remember I have already told you how many old persons who sustain fracture of the neck of the femur die of pneumonia. There is an essential differences between acute crupous pneumonia and this form which occurs in the aged. The cause of the latter is a failure to maintain the equilibrium of the circulation, a sort of congestion of the lungs results and this develops into a broncho-pneumonia. This patient probably had surgical kidney which is a very definite name for a rather indefinite lesion consisting of minute abscesses in the kidney, a pyelitis and distention of the pelvis of the kidney. His urine did not reveal this condition because there was so much pus from the bladder that even a microscopic examination was not sufficient. I want this case to serve as a lesson that in elderly people or, in fact, in any patient with diseased kidneys and with a consequently imperfect urinary excretion, there is a greater liability to bronchitis or broncho-pneumonia or even cardiac troubles, both pericarditis and endocarditis, than in other patients. Every now and then it happens that a patient is lost from some complication of this kind. Some time ago, I lost a patient on whom I did a laparotomy for gun-shot wound of the abdomen, the cause of death being inflammation of the pericardium.

COLD ABSCESS OF THE HAND.

This young woman came to me several months ago with a skin disease about the hands and wrists which resembled lupus and which was regarded by Dr. Wende, myself and several others as tuberculosis of the skin. She was treated with inoculations of tuberculin and with various external applications. Some time afterward she developed a fluctuating swelling in the ball of the thumb which I diagnosed as cold abscess and opened, letting out a quantity of caseous, puruloid matter. There persists a sinus which discharges and I shall to-day open it freely and curette its walls. You will notice that I do no more cutting in the palm of the hand than can be helped as I wish to avoid cicatrical contraction.

There is also on the back of the wrist a fluctuating swelling which is probably a distention either of the bursa or of the tendon sheaths. On making an exploratory incision, the accumulation seems to be entirely of serum and not sufficient to warrant further interference.

I have scraped out the sinus in the palm and have packed it with iodoform gauze. We shall in all probability have closure of its walls with granulation tissue or, as it was formerly called, by second intention. The exploratory incision on the back of the wrist I will close with catgut.

RUPTURE OF QUADRICEPS TENDON.

Some two months ago, this patient was injured in a peculiar way by a run-a-way. The tendon of the quadriceps extensor was torn off from the patella and there was a fracture of the external condyle of

the femur—in fact I think that more than the external condyle was broken off. I did not see the patient until a few days ago. At that time when the dressings were removed I found no attempt at union of the bone and the quadriceps tendon was drawn up and contracted. If it were simply non-union of bone, this would be a very fair case in which to test Brainerd's operation of drilling the bone in several directions in order to excite the formation of inflammatory callus. But there is also to be considered the condition of the muscle which, if not corrected, will surely weaken the limb. I purpose therefore, opening the knee joint and trying to sew the tendon to the patella as well as fastening the fragment of bone to its proper place. On moving the leg you will see that there is free movement above the knee, indicating that there has been fracture of the femur just above the condyle.

A transverse incision was made over the patella in order to expose the fracture. The bone ends were not sharp but were covered with connective tissue. In order to make them unite, this material was cut away and the fractured surfaces freshened with scalpel and bone forceps. The quadriceps tendon was sewed to the fibrous investment of the patella.

A CONTRIBUTION TO THE HISTOLOGY OF METASTATIC PHLEGMON.

Bunday (*Centralblatt für Chirurgie*, April 16, 1892), says, the explanation of the cause of extensive cell tissue phlegmon, inflammation of the serous membranes and the joints by pyæmia, is very difficult, and especially so when the metastatic formations by septic emboli or by cocci emboli cannot be recognized in the capillaries. The author presents the following conclusions from his studies:

"It is not at all necessary that the mechanism of the embolus, or particles of tissue, or masses of cocci should make a metastatic abscess, but the endothelial cells of the blood-vessels are inoculated by the microörganisms circulating through the blood, grow with great rapidity, break through the wall of the vessel and go to production of phlebitis and thrombosis, and still later, phlegmona. This condition is generally diffuse in contrast to the circumscribed embolic abscess, and is due to the histological arrangement of the tissue."—*Univ. Med. Mag.*

SURGERY OF THE GALL-PASSAGES AND LIVER.

By DR. W. KÖRTE,
BERLIN, GERMANY.

(*Continued from the last issue of the* REPORTER.)

The following are the histories of the other patients operated upon by me.

Empyæma of the gall-bladder; adhesion of the same to the abdominal walls; obliteration of the cystic duct; incision and recovery.

CASE VIII. Mrs. W., 69 years old. Twenty-five years previously the patient had suffered from "stomach cramps." For two years previous to her admission she had frequent pains in the region of the stomach and became greatly emaciated. Five weeks previously she was taken ill with severe pains in the region of the liver, accompanied by chills and fever.

The patient was admitted July 7, 1890. The abdomen was distended and the liver reached down to the level of the navel. At its lower edge was a fluctuating growth, and the skin over this was inflamed.

On July 8, 1890, an incision was made and about one quart of fœtid pus evacuated. From the abscess cavity the finger could be introduced into a large cavity attached to the abdominal walls, which stretched upwards under the liver and had apparently walls of mucous membrane. This was the gall-bladder. It was found to contain no stones. The cystic duct could not be sounded. The cavity was drained and tamponed with iodoform gauze. No gall was ever evacuated. The cavity slowly healed up, and the patient was discharged on September 11, cured.

Cholelithiasis; empyæma of the gall-bladder; carcinoma of the pancreas and liver; abscess of the liver; cholecystotomy at one sitting; evacuation of stones; death

CASE. IX. Mrs. K., 53 years old. Fifteen years previously, after a child-birth she began to suffer from symptoms of gall-stones. These troubles increased in severity after each child-birth. Seven years previously she passed gall-stones, and at the same time had icterus. She took the Karlsbad cure several times. Two months prior to admission she fell ill with severe

pains in the liver, and was unable to retain almost any nourishment. She again had icterus, and once passed some small gall-stones. She became greatly emaciated and lost in strength.

The patient was admitted August 17, 1891.

The patient was a moderately strong woman with a pendant abdomen. There was a slight icterus. The tongue was coated. The liver dullness began at the sixth rib and reached on a line with the nipple to the level of the navel. Here one could feel a rather flat, round growth, tense but not doughy, and painful to the touch. The supra-clavical glands were not enlarged.

Diagnosis: Cholelithiasis, and possible carcinoma of the liver.

On August 19, the operation of cholecystotomy was performed at one sitting. The longitudinal incision was used, and the tumor was found to be covered with adhesions, which were partly divided. The under-surface of the liver was hard and thickened. Puncture of the scarred and thickened wall of the gall-bladder revealed the presence of pus. This organ was then sewed to the abdominal wound and opened. The incision allowed the evacuation of a quantity of pus (containing staphylococci) and thirty-one gall-stones, after the removal of which clear gall was evacuated. A drainage tube and iodoform gauze was placed in the gall-bladder.

After the operation the pains diminished and the abdomen remained soft. Flatus and fæces were passed by the bowels. The patient, however, continued to grow weaker, recovered but poorly, and vomited frequently. Then the tongue became dry and the "sensorium" affected. Death occurred on September 2.

Autopsy: Peritoneum smooth and glistening; Carcinoma of the pancreas, liver and retro-peritoneal glands; gall-bladder free from stones and pus. Ductus choledochus buried in cicatrical tissue, and distended in parts. In these distended portions stones of the size of a pea were found. In the liver large abscesses were found corresponding in place to the gall-passages.

Empyæma of the gall-bladder occasioned by gall-stone; partial necrosis of the wall of the gall-bladder; cholecystotomy at one sitting; recovery.

Case X.—L. R. The patient had given birth to two children, the last time being during the first of March, 1891. During the first part of September, of 1891, she became suddenly ill while operating a sewing machine, and experienced severe pain in the regions of the stomach and liver. She was given morphine and opium, and subsequently a swelling appeared under the ribs of the right side. The patient was admitted to the hospital on September 29, 1891. She was then in fever, with a dry tongue and distended abdomen; she was also rather apathetic. After evacuation of the bowels a roundish enlargement could be felt below the arch of the ribs. It was sensitive to the touch. There was no icterus and the fæces were of normal color. The urine was normal.

There were slight evidences of septic infection, such as the dry tongue, quick pulse, and apathetic condition.

On October 2, 1891, a transverse incision was made, parallel to the arch of the ribs. The edge of the liver lay deep in the abdomen, and under it the tensely distended and fibrin covered gall-bladder. On the left side of the gall-bladder there was a discolored patch about the size of a fifty cent piece. The organ was then punctured, and found to contain a putrid fluid. It was then stitched fast to the peritoneum at the abdominal wound, and the necrosed portion covered with iodoform gauze. Incision allowed the evacuation of a large quantity of yellow pus, and three cubi-form stones varying in size from 1 to 1.5 cubic centimetres. The one stone was found wedged in the cystic duct, and after its removal the clear yellow gall made its appearance. The gall-bladder was now rinsed out with a ½ per cent. lysol solution, and a protective dressing applied.

There was a large secretion of gall through the opening in the gall-bladder, but no symptoms of peritonitis. Fever, dry tongue and rapid pulse, accompanied by loss of appetite still continued for about two weeks. The stools (passed after the administration of castor oil or calomel) were partly colored and partly gray. From October 5, there was general icterus.

The prognosis was doubtful for a long time; there remained the possibility of the presence of pus, but repeated punctures resulted negatively.

From October 12, the patient was

given luke-warm baths daily, and her condition improved from that time. The tongue became moist and the appetite picked up. The necrotic portion of the gall-bladder sloughed away.

On November 14, the gall-bladder fistula was plastically closed, and healed well. The patient reported in good health during the first part of January, 1892. From the putrid contents of the gall-bladder pure cultures of the *bacteria coli commune* (Escherich) were obtained.

Cholelithiasis; subphrenic abscess; incision, after resection of the eighth rib; empyæma of the gall-bladder; abscess of the liver; incision of the gall-bladder and liver; occlusion of the choledochus duct; cholecysto-duodenostomy; recovery.

Case XI. Mrs. G. forty-eight years old. During the youth of the patient she had suffered occasionally with "stomach cramps." She was taken ill during the latter part of December 1890, with pain and swelling in the region of the liver. These symptoms gradually increased until on January 10, 1891, they became unbearable, tearing pains. The patient was admitted January 11, 1891.

The liver dullness reached to a level with the navel, and upwards to the fifth rib.

On January 17, the liver dullness had extended upwards to the third rib, and at the back to the angle of the scapula.

On January 19, punctures were made on a line with the mamma in the fourth, fifth and sixth intercostal spaces, and a stinking pus evacuated.

The eighth rib was resected in the mammillary line; the pleura opened, and an iodoform gauze tampon carefully inserted; then the diaphragm incised and a large quantity of fœtid pus evacuated. A slight exudative pleuritis resulted, and the abscess became rapidly smaller. The pain continued at the border of the liver, and the fever remained.

On February 3, puncture of the protruding liver revealed pus. An incision was made parallel to the border of the ribs, the gall-bladder opened and a quantity of pus and twenty-six stones evacuated. An abscess in the liver, to the left and above the gall-bladder was also opened. The fever now gradually grew less. At first the discharge of gall was but slight, but on February 19, it grew to be considerable. At the same time the stools became clay colored. The free discharge of gall continued in spite of the plugging of the fistula. The use of Karlsbad salts increased the secretion.

As the patient became much emaciated, having lost twenty-eight pounds since the first of January, on May 21, 1891 the operation of cholecysto-duodenostomy was performed. A transverse incision was made at the border of the ribs, and from the middle of this a longitudinal incision reaching ten centimetres downwards. The gall-bladder was found firmly adherent to the mesentery, colon and duodenum. The choledochus duct could not be laid bare. The duodenum was then stitched fast to the gall-bladder, and both organs incised. The edges of the incision were then sewed together. The application of the suture so deep in the abdomen proved most laborious, but was successfully accomplished. The old gall-bladder fistula was then closed by suture. An iodoform gauze tampon was then inserted and the abdominal wound partly closed. In the evening the patient vomited a yellow fluid.

On March 26, the fæces became normally colored. The abdominal wound healed by granulation without complication. A stubborn bronchial catarrh delayed the recovery. Subsequently several sutures from the fistula sloughed out of the wound.

The ultimate results were complete recovery, and large increase in weight.

Cholelithiasis: occlusion of the ductus choledochus; cholæmia; cholecystotomy at two sittings; later cholecysto-enterostomy at two sittings; death.

Case XII. H., male, 54 years old. The patient had been ill since the Christmas of 1889, suffering from gall-stone colics. Icterus since the middle of May, 1890.

The patient was admitted July 14, 1890, with symptoms of severe cholæmia, intense icterus, chills, and attacks of colic. The fæces mostly acholic. The general condition of the patient was unfavorable in the extreme.

Diagnosis: Occlusion of the choledochus through stone or malignant tumor. In the region of the gall-bladder a growth could be felt at the margin of the liver.

July 29, 1890, cholecystotomy at two sittings.

The incision was made parallel to the margin of the ribs. The enlargement proved to be a cyst in the right lobe of the liver. The gall-bladder was small and strongly adherent. No stone could be felt. The gall-bladder was then stitched to the abdominal wound, and subsequently opened on August 4. After the second day there was a free discharge of gall. Twice the patient had chills, accompanied with pain in the liver, and high fever, but after that the course was non-febril. The stools were for the most part entirely acholic, but occasionally traces of gall could be seen. The urine was of a light color, and free from gallic coloring matter. The appetite improved.

In spite of a most nutritious diet the patient continued to lose flesh, and after much persuasion agreed to submit to the operation of cholecysto-enterostomy. The first part of the operation was performed on September 29, 1890, and the gall-bladder fastened to the colon. A longitudinal incision was used, close to the rectus muscle, and from this incision another careful search for stone in the choledochus was made; but in vain, for the adhesions were so many and so firm that it was quite impossible to lay bare the choledochus duct.

The second part of the operation was performed on October 3, 1890. The intestine opened, and sewed to the gall-bladder. Iodoform tampon inserted in the abdominal wound. The patient continued to lose flesh; a few stitches cut through and fæces were discharged through the wound. Death occurred on October 6, 1890, from gradual collapse.

Autopsy: Peritoneum entirely smooth and glistening. Transverse colon adherent to the gall-bladder. Dense adhesions surrounding the gall-bladder, including the cystic, hepatic and choledochus ducts. No stone to be felt. Liver and neighboring organs removed; and the choledochus followed from the duodenum, and finally a stone the size of a cherry found in the choledochus close to the opening of the cystic duct.

Cholelithiasis; Dropsy of the gall-bladder with beginning empyæma of the gall-bladder. Occlusion of the choledochus duct; suppuration of the liver; cholecystotomy at two sittings; death.

Case XIII. Mrs. B., fifty years old. For three years past she had suffered from frequent cramp-like pains in the regions of the liver and stomach.

On the 31st of October, 1890, she was suddenly seized with severe chills, fever, pain in the region of the liver vomiting. There was intense icterus.

On November 3, the patient was greatly collapsed, her tongue dry, "sensorium" affected, and highly icteric. The abdomen was distended, and painful to the touch over the region of the gall-bladder, which latter organ was distended. Cholecystotomy at two sittings was performed.

On November 3, the first portion of the operation was undertaken. The gall-bladder, which was strongly adherent from below, was laid bare; it was impossible, however, to lay bare the choledochus duct on account of the adhesions. No stone could be felt. The gall-bladder was then stitched to the abdominal wound, and was opened on November 6. A light yellow gall was evacuated, and a few pus corpuscles, but no stones. Neither could any stones be felt in the cystic duct with the sound.

The temperature of the patient fell greatly, and she continued afebrile. The sluggish sensibilities were not improved and the icterus continued in spite of the discharge of gall.

Death occurred on November 16.

Autopsy: Peritoneum smooth and glistening. Dense adhesions at the under-surface of the gall-bladder. Even now no stone could be felt. The liver and neighboring organs removed and the gall-passage traced from the bowel, and a stone the size of a hazelnut found at an ulcerated part of the choledochus duct, close to the opening of the cystic duct. In the liver multiple abscesses were found, containing small gallic concrements.

(*To be continued.*)

PILOCARPINE IN DERMATOLOGY.

Employed hypodermically, pilocarpine has proven useful (Simon, in *Br. Mcd. Jour.*) in case of chronic eczema which had resisted baths, arsenic and iodides. One case was completely cured by 110 injections administered within as many days. The remedy is without effect in psoriasis, and seems contraindicated in subacute forms of eczema.

Communications.

ASTHMA: ITS INTRANASAL ORIGIN AND SURGICAL TREATMENT.*

By HENRY L. SWAIN, M. D.,
LECTURER ON DISEASES OF THE EAR AND THROAT, YALE UNIVERSITY, NEW HAVEN, CONN.

A few years ago and this subject was the talk of the rhinological world, being taken up on all sides with great avidity. As a result of this ardor much hasty work was done and conclusions drawn, and it seems now quite fitting that, with enthusiasm tempered by time and with the calmer judgment acquired by judiciously estimating results, we weigh matters pro and con, endeavoring to get at the exact truth. The question might then be put somewhat in this way: Are the present ideas which connect bronchial asthma in its pathology and causation with certain existing diseased conditions in the nose correct, *i.e.*, borne out by demonstrable facts? Secondly, do the results of the treatment, having in mind the relief and cure of these same nasal troubles, warrant their further continuance?

The endeavor will be to bring forward positive evidence in favor of above theories and to let the results of treatment as detailed by the author, after outlining the nature and methods of carrying out the same, speak for themselves.

In attacking the first part of the problem, let me carry you back into the history of its progress and development, for on such an occasion as the present anniversary, one is justified in referring to the past, that he may the more accurately portray the present. Something like fifteen or twenty years ago Voltolini reported some cases where, after the removal of nasal polypi, the asthma from which the patients suffered was relieved, and in one case permanently cured. Following the record of these cases numberless reports from various sources came to light and soon every specialist, at least, was bringing to light his achievements. Still further impetus was given to investigation and experiment by the results obtained by certain observers in the treatment of hay fever and hay-asthma by removing all the pathological conditions in the nose. The impetus thus given was tremendous, but soon a reaction became apparent, a revulsion of opinion which is to-day still evident. Especially in proceedings of societies one could see that while not doubting the fact that some cases could be relieved by treatment applied to nose, by no means as many were made to respond to said treatment as appeared in first reports, hence the method was brought into some disrepute. What popular idea does not suffer the same? The radicals, who were quoted as believing that any cases of asthma could be in a measure relieved by nasal treatment, were compelled to take a part of the statement, and the conservatism went along in the old rut worn deep by time, of asthma being a strictly nervous phenomenon, certainly a very non-committal statement. Neither position is tenable, but the latter makes no advance on the old theory of by-gone ages, and leaves us still at the mercy of nervines and potassium iodide.

Taking it for granted that I am understood in speaking of the nasal treatment as meaning those methods usually in vogue, namely, removing obstructions to easy breathing and aiming to attain permanent potency of both nostrils in as nearly equal degree as is possible, these ends being attained by the removal of polypi, cauterizing turbinate and other hypertrophies, and in various ways removing bony obstruction, we need not now attempt to analyze the results of these measures for it will be done later. Neither do I think we shall arrive at the reason for the difference in opinion as to effectiveness in this way, but far sooner in considering and in reconciling the views as to the nature of asthma, and the explanation of the various component phenomena which make up the classic attack of asthma.

There are two general classes of opinion as to the nature of asthma; the conservative which considers the entire affair as a purely nervous, hysterical manifestation, and would treat it entirely as a neurosis, and the radical, which would make it almost altogether a local phenomenon and allow the neurotic element to sink into complete insignificance. In other words, there must be some organic disease present, not merely diseased function. The only organic diseases which have been ex-

*Read before Connecticut State Medical Society, May 28, 1892.

tensively connected with asthma are those of the nasal cavities, and yet even the most radical of those who look upon the nose as *fons mali* make it, the nose, simply the starting point of the attack. This, of course, involves something out of order with the other parts of the respiratory apparatus, and perhaps of the individual as a whole, otherwise every one with nasal stenosis would be having asthma. The attack of asthma itself is generally explained in one of two ways, either that of bronchial spasm, or vaso-motor disturbance, both explanations being as one in the point of narrowing the calibre of the finer bronchi. Having decided which of these theories is the more rational, we shall then by easy transition prove that the nose originates the attack frequently, if not most always, and hence the logical outcome, that we must treat the nose in such cases.

The attack of asthma begins with a sometimes sudden, sometimes gradual feeling of oppression about the chest and a desire to cough. Perhaps there are also symptoms referable to the nose, either preceding this or at the same time, and these are sneezing, free secretion from the nostrils, with stoppage of one or both. Simultaneously there can be heard in the thorax small shrill whistles. As a result of this oppression or of the coughing, the person begins to inspire deeply, finds it difficult to get the air in and so is led to make greater and greater efforts. From the very first there is a marked contrast between the inspiration and expiration. The former always more marked, and resulting from greater effect than the latter, is now very much augmented, while by contrast the expiration is even less than usual and is made also with distinct effort, that is, there is obstruction to both inspiration and expiration. As the feeling of oppression becomes more intense the inspirations grow stronger and succeed one another more rapidly, allowing less and less time for expiration, especially as this is labored. As this continues but one result can be possible, namely, that of distension of the thorax, so that in extreme cases we find the chest walls almost fixed in position of full inspiration, while the patient still tries to take a little more air into his distended lungs that he may freshen his cyanotic blood. This extremely distressing condition of things lasts a variable time and suddenly or gradually there is a relaxation, something lets go, a more prolonged expiration is possible, the distension is relieved, and once more the patient has the breath of life within him.

Now, what have we here? Evidently—First, obstruction to the ingress of air into lungs—the oppression first noticed—and this must of necessity be one or another form of narrowing of the finer and large bronchial tubes as evidenced clearly and plainly by the fine whistles which had not previously been present, and later by the wheezing. Secondly, the air when once sucked in cannot easily get out again, something obstructs the egress of air. It cannot get out as fast as it comes in. Probably this latter is due to the same cause as first. Thirdly, as a direct result of one and two we have distension, expiration being at first difficult becomes almost impossible. Fourthly, a cessation of hostilities, that is, relaxation of the obstruction to breathing, always accompanied by a copious discharge from the mucous membranes of bronchi and nose, the relaxation being perhaps dependent on the latter, probably causing it. These secretions are always characterized, whether from nose or bronchi, by certain constituents, namely, asthma or Leyden's crystals, and so-called eosinophilous cells. Curschman has some peculiarly shaped spirals named after him, and other peculiarities have been described, but the first two are almost constant. These same things are present it is true at other times than when the attack has occurred, but are always much more abundant in the secretions, following the paroxysm. These facts involve the existence, first of a specific or asthmatic catarrh of the bronchial mucous membrane and especially nose. Secondly, as a result of above possibly, an irritability of the bronchial muscular fibers, which alone can produce any considerable narrowing. Thirdly, an exciting cause, atmospheric change, late supper, sudden cold, and numerous others. Fourthly, by inference and clinical fact the neurasthenic habit, which renders it possible for the three preceding to concur together.

We have then first to prove that narrowing of the bronchial tubes exists. If this is so, then, as intimated, the rest of the problem can be completely and adequately explained almost from a mechanical standpoint.

Bronchial spasm was one of the earliest explanations offered, but according to previous interpretation proved somewhat inadequate to the perfect clearing up of all the phases of the attack. As a result a new theory was proposed, namely, vaso-motor distension, and by others the first theory was supplemented and was supplanted by spasm of the diaphragm. This latter while not even necessary to help out the first, certainly as a complete explanation can be excluded without further discussion, for first, chronic spasm of the diaphragm only occurs with general tetanus; clonic spasm only in hysterics or by singultus. Secondly, who ever heard of an attack of asthma beginning with spasm of the diaphragm.

Have we any definite proof that bronchial spasm does exist in these attacks? First, we have the very important fact that there are muscular fibres in the bronchial tubes down to the very ends of the same, and that the contraction of these fibres does narrow the tube. Secondly, that such spasms do occur at other times in other parts of the body is sure, and I need only instance intestinal colic and stricture, as evidence. Then there must be some obstruction to the entrance of the air into lung, which did not previously exist, and which is bitterly complained of by the patient, indeed it is the first thing he notices. At the same time comes the shrill whistles in the chest, which can be explained only on the theory of air going through a small place, hence a smaller place than existed before they were heard, *i. e.*, a narrowed bronchial tube. Edinger and Riegel also long ago proved that stimulation of the vagus made the pressure in lung lobule or bronchial tube greater, and that a bronchial muscular contraction could be produced experimentally. Now, all of these facts receive still further proof in the experiments of Lazarus. Not satisfied with simply finding that pressure rose in the tube, he showed that in an animal that was apnœic and curarized, in which artificial respiration was being kept up, that a distinctly greater resistance to the entrance of the air into an air-tight lobule existed when the peripheral end of a cut vagus was stimulated. It requires a very slight current indeed to make a variation in the mamoneter. This, of course, must be due to narrowing of the bronchial tube. To exclude the other causes he injects into muscular tissue atropine, so that the stimulation of the vagus cannot affect the heart, and thereby excludes any vaso-motor influence, and he gets the same obstruction to the air current. Another interesting point was that by applying electricity to the interior of the nostrils with vagus intact, an exactly similar effect was pro duced upon the mamoneter, thus proving that irritations in the nose can have a direct influence upon the bronchial muscular tissue, and that this influence may be to narrow the calibre of the tube. Thus it is plain that the difficulty in getting air into lung lobule and also into chest must be due to spasm of bronchial muscular fibre.

The same muscular contraction must be the explanation of the difficulty in getting the air out of the chest. If a tube is narrowed it transmits the same amount of air with a greater resistance in which ever direction the air moves, in or out, or if the resistance cannot be overcome it transmits less. Our muscles being developed as they are inspiration can be made a more powerful effort then expiration, hence allowing that the amount of time was the same in the two cases, less air could go out than could come in when the inspiratory muscles were working their fullest purpose. Sometimes, however, inspirations heap up one on the other rapidly, then some inspired air of each effort must remain behind and by successive increment we soon have the lungs distended. If this should not suffice, however, to explain all the details, there is still another point. The researches of Miller, as stated in a preliminary report, show us that the lung lobules do not connect, and that the air space connected with any one terminal bronchus is, in proportion to the size of the tube, very great. For instance, the average bronchus ends as a tube about 0.4 m. m. in diameter. From this three to six openings lead away toward the end of lobule. These are called vestibules, are about 0.2 m.m. in diameter, and have as they leave the bronchial tube a complete ring of muscular fibre around them. They open into the atria, spaces twice as large as themselves, and from each atrium open two or three passages to the air sacs, which are twice as large as the atria. Around the air sacs are the air cells which bud out in all directions from them, each of them being about half as deep as a vestibule is

wide. Now, a simple mathematical calculation will show that even by flat measurement we have a space at least 12 to 20 times greater than the normal opening is from the bronchus to one of its vestibules, and 30 to 100 times greater space than the bronchus itself. Now, narrow this bronchial tube, make the openings from it by virtue of their own little sphincter of muscle also smaller, make your inspiration powerful to distend them thoroughly with air, then think what resistance these small openings will present to the air coming out. As the distension increases the openings may become pressed upon and narrowed still more, and as one inspiration follows on the other faster or deeper than ever, urged on by the stimulation of blood in the centers of respiration, we must have a balloon-like distension of the lobule and the impossibility of the chest walls collapsing as they should. If the spasm lasts long and is great, think how much these thin-walled spaces must become distended, the walls themselves stretched by the pressure of the chest walls, and is it any wonder that the confirmed asthmatic is found to have dilated vesicles and seems to have as a result but little motion to chest. Certainly abundant testimony tells us of the distension which must be due to air not getting out.

The relaxation of such a spasm may, of course be very gradual or sudden as was the onset. The simple relaxation allows the air to go out, the stagnant air in the lobules has a chance to be oxygenated, the inspiration becomes less forced, distension diminishes, and abundant discharge becomes evident both in nose and lungs. Here is where the vaso-motor men claim that the present theory is weak, but action and reaction are equal and in opposite directions. Certainly as regards the lungs we need no vaso-motor help. During the period of spasm there could not be free circulation, the walls of the capillaries would be relaxed, and when the change came what could be easier than transudation? And the secretion is very clear and frothy. To bring about the nasal secretion at the end of the attack, as also to connect the initial step in the attack from the nose and bronchial membrane, we have the experiments of Lazarus to help us out. But nevertheless a little vaso-motor influence must come in. Yet while granting this, I cannot see how any further effect can be laid to the door of the vaso-motor system. To suppose that by the slight narrowing of the tubes which would result from the distension of the blood-vessels in the bronchial mucous membrane, enough resistance could take place to explain all the phenomena of an attack of asthma is to me an absurdity. Again, why do we not have asthma in mild form by every attack of bronchitis when this latter is seen. Surely the blood-vessels are congested and that continuously, and if narrowing ever takes place from that cause it should be then. And again, to the best of my knowledge and belief it has never been demonstrated that the bronchial mucous membrene contains any such rich plexuses as would be necessary to produce any essential narrowing of the tubes by their engorgement. Even the later researches of Miller leave it doubtful, although he distinctly states that there is a rich capillary net work directly under the mucous membrane of the finer bronchioles. The venous radicals immediately leave the surface, gather into larger trunks, and then empty into the pulmonary veins, so there is not the interlacing of venous trunks near the surface which we more commonly find when a mucous membrane is distensible. Hence it would seem that the only use to which we could put the unquestioned association of reflex influences in the vaso-motor systems of the two places is to explain the initial step in the attack. Those who attach more importance to the various peculiar constituents of the sputa, the asthma crystals, and the eosinophilous cells, would reason that they perhaps indicated a peculiar form of catarrh in both nose and bronchi. Beginning in the nose perhaps there would be a vaso-motor disturbance which would lead to the secretion of these various materials there. At the same time these occur as a result of the same secretion in the bronchial tubes, and we have the irritation produced which brings on the bronchial spasm, the vaso-motor system being the link. When the spasm lets go at the end of the attack, free transduation takes place and the irritating particles are washed to the surface, while a similar event also transpires in the nose; vaso-motor system again the link. This puts a strong dependence upon the nose to start the attack. The nose is, of course, more exposed by its position than any other part of the respiratory tract,

hence more open to all irritating particles which come in contact with it. It is to be demonstrated beyond doubt that in the case of hay asthma, that the changes in the nose produce and precede the attack of asthma. Therefore, it is possible for a nasal lesion under proper conditions to produce or to initiate the impulse leading to an asthmatic attack, and, of course, if it can do it in this case, there is nothing wrong in the supposition that perhaps in most cases of asthma connected with nasal disease, the same may be true.

We have assumed that there is a sort of specific catarrh of both nose and bronchi, for we have the matter spoken of as always present both in and before an attack. Personally I have examined a few of these cases, and hope to do so to more, and have always found an asthmatic to have more eosinophilous cells present in his sputa than is usually the case in other catarrhal conditions, some apparently identical in appearance If the blood is examined in these cases we also find more eosinophilous cells than the normal, although they are not found exclusively by asthmatics.

In a young man at present being treated for mucous polypi, these same cells were abundantly present in the nasal secretion. During the course of the treatment he caught cold and had a slight bronchitis. When almost over this he came to my office and was operated on by removing a few polypi. His bronchitis immediately became worse as the reaction following the operation started up in the nose, and he had his first attack of asthma. His nasal secretion examined at that time, as also blood, showed many eosinophilous cells, more than he had before or has had since, and he has had other apparently equally severe colds with coughing and expectoration. Here is an indication too pointed to pass. First, the nasal disease existed with its altered secretion of a certain type; secondly, operating on the nose still further altered the secretion and blood as well, coming at an unfavorable time, and then he had his asthmatic attack, having previously acquired an irritable condition of the bronchial mucous membrane.

Now, while it cannot be said that the nasal disease always must previously have existed in order to bring about the condition necessary to produce the asthmatic attack, certain it is that such is frequently the case, and that in almost every case of asthma the nose is somewhat diseased. Secondly, as there is surely the nasal phenomenon beginning an attack of hay fever asthma, brought about by the pollen of the certain plant which produces it in the individual case, so also could it be possible that an atmospheric influence on a diseased nasal surface might produce an altered secretion, or might of itself be sufficiently irritating to start vaso-motor disturbance. Then either in this way or by the direct nervous reflex, as in the experiments of Lazarus, the bronchial mucous surfaces take up the disturbance and we have the attack. Further we can clinically bring on an attack of asthma by irritants, chemical and mechanical, applied to the nose and reversely stop attacks by cocainizing the nostrils. This is not to be understood as saying that every attack begins with the nose, for a late supper, or any other indiscretion of diet may be the source in some instances, but granted that most of the disturbances must be in some way connected with atmospheric conditions as would seem to be the case in that they seem to come by changes of weather, at a certain time of day or season of the year, then it is rational to suppose that the nose would get the first impression, and hence that this impression might originate the attack. To trace the exact nerve tract will be difficult for the experiments of Lazarus only prove that the pneumogastric plays some part, although, as just stated, it proved that it could produce in some way contraction of the bronchial fibres. Then, is it also mere chance that only certain classes of troubles of the obstructive and vaso-motor order occur in these cases in the nostrils; that the certain crystals and cells are present in the secretion both nasal and bronchial; and that in the case of the eosinophilous cells they are present in the blood of the patient, and are more numerous in the secretion at times of attack than otherwise? The exact answer to this latter point is not yet possible, but does present many interesting possibilities.

Confronted then with the facts, which I beg to bring once more before you, namely, that of the unquestioned connection of the hay fever nasal symptoms and the existing asthma, of the physiological experiments of Lazarus and others, of the position of the nose so clearly first to take the changes of atmosphere and the brunt

of many irritations, and the clinical fact that many of the noses in cases of perennial asthma are unquestionably diseased and in all there exist altered secretions, as also in bronchi and an altered blood, would it then be any severe stretch of imagination or reasoning to say that there might be a possibility that the severe nasal disease existing in any case of asthma might be the cause of the trouble? Not the only cause, perhaps, but sufficiently so that when the nasal trouble is removed the attacks of asthma would cease? And if this latter is the case may we not hazard the statement that bronchial asthma may be an intranasal disease, in the same sense that we might say that many ear diseases are intranasal, catarrhal diseases, for although local lesions exist there, still they are due to the previously existing nasal trouble, are produced by it, and cannot be cured until the latter is removed?

It would at this juncture be a pertinent inquiry: How many asthmatics came under this head? Very many indeed in the sense that the treatment was eminently successful in helping them, yes in curing them.

Ever since beginning practice, I have been steadily at work on various cases, accumulating observations and ideas on these points, somewhat unmindful of the work done by others. Lately a number of writers have presented tabulated statistics of cases, and showed a large number of cases cured and relieved by treating the nose. And curiously enough, I, who had not been a very great enthusiast, find my percentage of "cures" to be nearly as great as the most sanguine. Before giving any figures it might be well to define what cases are to be considered cured. We are treating the individuals for asthma and nothing else in this estimate, and we consider a person cured of his asthma who has none of his sharp, asthmatic attacks for a period of a year or greater. We do not feel ourselves as vitiating the statistics when we also consider a person cured of his asthma who may still possess the chronic bronchitis so frequently present in these cases, and who may be heard to wheeze a little after a hard coughing spell, or other severe muscular effort. As "relieved" we shall, of course, make two classes, those nearly cured and those but little benefited by treatment. A fourth column of failures will also figure in the description.

Dr. Bosworth gives in his book an exceedingly interesting tabulation of eighty cases of asthma treated for the relief of the nasal trouble, thirty-four were hay asthma, forty-six perennial asthma. Of these, nineteen of the first were cured, and fourteen improved; of the second, twenty-eight were cured, and twelve improved, so that out of the whole eighty only seven were not benefited by the treatment, and of this seven there were five cases in which the result is unknown. So that classing these last with the unimproved, and we still have a large percentage of improvement, forty-seven of the eighty cases were cured. This was in 1888, and in 1891 he could say that he felt quite confident that in but six of them marked "cured" have relapses occurred, and in none of them are the present attacks as severe or as frequent as the previous ones. Since then he presents tables of eighty-eight other cases of asthma, in eleven of which results are unknown. Of the seventy-seven, who were thoroughly treated, forty-two were cured, thirty-three improved, two unimproved, figures surprisingly close to the first ones reported.

I have to add to these figures the modest number of twenty-nine cases, twenty-three being perennial asthma and six hay asthma. Of the first, thirteen have been cured, five have had no attacks since treatment was well under way, but have not been long enough immune to be classed as cured. Three were improved, two unchanged except that their catarrh was better. The hay asthma was half improved, two cured, and one suffered very slight relapse last year. Of all cases which have applied for asthma during the time covered by the rest, in only two or three did I find nothing sufficiently wrong in the nose to consider it justifiable to operate. It will be seen from these figures that the results are very nearly the same as those previously reported, and as they were made entirely independently and without previous strong prejudice, as well as carefully compiled, their testimony is when taken with the others such, that "he who runs may read."

In all of the above cases within the experience of Dr. Bosworth and myself the nasal treatment was undertaken with the idea of relief and removal of some form of obstructive lesion in that cavity. My

own cases have presented a larger majority of polypi than any other single lesion. The others were either cases of simple but severe hypertrophies in various parts of the nostrils, or the same resulting from or complicating bends of septum or other bony deformities.

The mucous polypi make necessary the most varied and complicated methods of treatment, for in the end to remove and thoroughly eradicate the same one frequently has to do all the usual operations which we perform in the nose. First, we noose the growth out with snare, removing every portion possible, and ransacking every nook and corner for a hidden mass. Having done this thoroughly we then cauterize the places where these polypi grew, as also all other hypertrophies. If there is any bony projection which is so great that by the simple swelling which must take place in the turbinate tissue during atmospheric changes, contact is brought about, then that must be removed beyond such a possibility. This rule is observed in all this class of operations. If, after these things are done and the polypi do not return, we have produced no relief to patient, but little more can be done to ameliorate his condition except the older methods of treatment. The main point, however is to see to it that the polypi do not return, for almost as surely as one is found large enough to exercise any pressure in the nose, just so surely there will be a return of the asthma. Conversely, your patient may and very frequently does not get any relief to his asthma until every vestige of polypoid growth has been removed.

Simple hypertrophies are cauterized until the same changes spoken of before fail to produce any points of contact with the septum or other parts of the nose. Simple hypertrophies are found, be it remembered, not only on the turbinate bodies, but also on the septum, and these are particularly liable to be very sensitive. For cauterizing I always use the galvano-cautery.

For removing bony projections the saw, chisel, and gouge or burr, have proved ample to the end of establishing proper freedom.

When the operations are done as well as also during the entire interval of their performance, the patient is directed to keep the nasal passages thoroughly clean by simple salt solution, or Seiler tablets, the same being followed by some alkaline and anti-septic powder. This is kept up until all catarrh has been reduced to a minimum. But do not suppose that all this time the other portions of the patient's system are being entirely overlooked; far otherwise. In all cases where owing to long standing the bronchial disease has become fixed, the potassium iodide and terpine hydrate, alternately or together, are used to mitigate the cough and to assist expectoration, always being given in free doses. The patients are shielded from colds, directed to take cold baths, and where possible to avoid indiscretions in diet, to lead a temperate life, and finally when the treatment is done, or is futile, if at all possible, a change of climate is advised—the last step. Hay fever patients particularly are sent away during the dangerous period, and are put into as near opposite condition to their usual environment as possible. When this latter is done for either kind of asthma, it will avail but little, when nothing more radical is done, for as soon as patient gets back again, the same conditions will be operative that previously were, and the asthma will return.

When all the above means fail, then we have simply to make life as easy as possible for the patient, keeping down the severity of his attacks. Here, as in the attacks the patients have during treatment, considerable can be done to relieve the distressing spasm by burning some of the various forms of either pastille of prepared paper which have all the most useful elements, potassium nitrate and stramonium or belladonna leaves or both. Morphine is the one drug that is at all efficient in diminishing the spasm, although much may be done with chloral hydrate and bromide. A confirmed asthmatic is exceedingly liable to become an opium taker. Of the newer drugs prepared, I know nothing from individual experience. May I then give in closing a single case which will illustrate the main points of treatment and result.

M. B., aged 27, consults me concerning his catarrh, which has been very severe during the last few years, and which occasionally stops his breathing through the nose. Lately chest has troubled him. and his breathing has become short. Very lately some asthmatic attacks, occurring

once every twenty-four hours at night. Such reads the record of April 17, 1890. On examination of the nostrils found mucous polypi in large numbers in both nostrils. Treatment was immediately begun, and on October 30th we had the nose entirely cleared out. The attacks of asthma ceased some weeks ago, and remained away for two months, patient being during that time quite negligent, in spite of warnings, because he felt so well. He was gaining in health and strength, the latter having been much reduced by the loss of sleep occasioned by his attacks.

On December 12th, he again returned, having had several very bad spells, the worst being one night after a wine supper. Several new growths had begun to appear, and when they were thoroughly removed the attacks immediately ceased. He then had another respite and later, January 30th, started for a trip West, notwithstanding the fact that in two places there were still unreduced "polyp-rests" present. He reached Buffalo and was attacked with asthma. Turning back to Syracuse where he had friends, he consulted a specialist there, who kept him under constant attention, but things went from bad to worse, until he was having several attacks daily, some of them of extreme severity. He then made up his mind to return to New Haven and did so. I found numerous masses had developed on the old "breeding ground," which we had not thoroughly reduced, and as soon as these were removed his attacks ceased, he having only one attack after operation of the first day. Still he did not get entirely in order before he ceased his attention, and he has had two or three short spells of asthma since, each terminated by the removal of the diseased tissues. He is still unregenerated, is at present in one of his periods of respite, and therefore had to be put in the "relieved" column in our estimate of results, although he could be surely cured.

The above case is one of many of those whom we classed as being only "relieved," and shows in short the results of treatment, the necessity of the most thorough measures, and the reason why more cases are not perfected.

I feel, therefore, justified in the light of the facts with which I have burdened you well-nigh to exhaustion, in stating that we have fairly demonstrated that there is a causative association between certain nasal diseased conditions and bronchial asthma; secondly, that the results of the treatment of these conditions contribute as much to the relief and cure of the asthma as any other single method of treatment now known, and very nearly as much as all others put together.

HYDROCHLORIC ACID IN THE TREATMENT OF VOMITING.

Dr. Alkiewicz, writing in the *Nowiny Lekarskie*, mentions that in various kinds of vomiting he has found great benefit from small and frequent doses of hydrochloric acid, well diluted, of course. In one case of the vomiting of pregnancy, where none of the ordinary remedies had any effect, hydrochloric acid proved successful, though it had to be given for a fortnight before it entirely arrested the sickness. In more than ten cases of cholera nostras in adults, with vomiting, hydrochloric acid was given with good results. Again, where vomiting was due to acute dyspepsia from errors in diet, and where it occurred in the course of influenza, scarlet fever, or other contagious diseases, the same remedy proved equally efficacious. —*Lancet.*

THE MECHANICAL TREATMENT OF TRACHOMA.*

By EDWARD JACKSON, M. D.,
PROFESSOR OF DISEASES OF THE EYE IN THE PHILADELPHIA POLYCLINIC, SURGEON TO WILLS EYE HOSPITAL, ETC.

The importance and dangers of trachoma, or true granular conjunctivitis, as a cause of suffering and blindness, and its spread by contagion, were well presented by Dr. J. A. Lippincott, in the address on ophthalmology, last year. An important factor in its transmission is its extremely chronic course. I have in mind a case which I saw and treated from time to time for ten years, the patient attending for a time, then getting weary and neglecting treatment for awhile, and anon returning with the cornea distinctly more damaged; aud during the whole of this period this patient was a possible centre of infection to those about her. And such cases are not exceptional, but extremely common.

It is rather exceptional to have a patient persevere steadily with treatment until the cure is complete. Last year I remember but a single case in my service at Wills Hospital who persisted steadily to the end, coming much of the time three times a week for applications of copper sulphate, and who was finally discharged completely cured just about a year after the treatment was commenced. There is still attending my service at the Polyclinic Hospital, for occasional applications, a girl who has been under pretty steady treatment with astringents for four years; and who is now about cured with some shrinkage of the conjunctiva. And during these protracted periods we have to deal not with sequellæ but with the active disease running its characteristic course. I cannot recall seeing a case of well-marked trachoma, even when taken early, that was thoroughly cured by applications of copper, alum, silver, and tannin in less than three months. Yet such treatment has been, and still is, mainly relied on for the radical cure of this disease.

In contradistinction to this, attention should be called to the results of mechanical treatment. Many attempts have been made in this direction, such as incising the trachoma granules, the little sago-like gray translucent masses that crowd the retro-tarsal fold and are scattered over the palpebral portion of the conjunctiva. Others have excised them, sometimes removing the whole retro-tarsal fold, greatly abridging the course of the disease, but also leaving a contracted conjunctival sac.

Others, led by Manolescu, had resorted to grattage, or brossage, scraping the whole conjunctival surface, or brushing it with a tooth-brush, the bristles of which were cut short to stiffen them, with or without the application of strong solutions of mercuric chloride. This latter method, if thoroughly applied, is effective in promptly cutting short the disease, but leaves such cicatrical contraction of the lids that its adoption seems scarcely justifiable.

In 1886 Dr. F. C. Hotz published his method of expression, which it is since claimed had also been practised many years before by Sir William Wilde and others. He pressed out the granulations from the upper lid and cul-de-sac with the thumb-nail, and from the lower lid by the aid of iris forceps, from which the corrugations had been ground off. This operation he urged could be done without a general anæsthetic; and he claimed that it greatly shortened the treatment of the most tedious cases, those with well-marked trachoma granules. I tried it, as did doubtless many others, under cocaine anæsthesia, and probably on account of failure to thoroughly express the contents of the granules, was not very much impressed by the method. Others, notably Drs. A. E. Prince and H. D. Noyes, devised forms of forceps for the operation, and practiced it with greater success.

Something over a year ago Dr. H. Knapp resorted to the roller principle, such as is applied in the common mangle or clothes wringer, to the expression of the trachoma granules, and devised a pair of roller forceps, here shown, for the purpose.

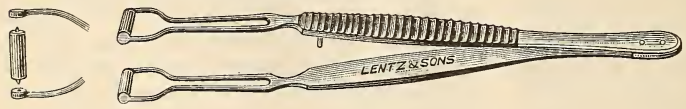
His results were extremely satisfactory, the mass of cases being cured by a single operation, often without necessity for subsequent treatment, and without cicatrices due to the operation. He reported them at the meeting of the American Ophthalmological Society last September, and they have been so far confirmed in the ex-

*Read before the Medical Society of the State of Pennsylvania.

perience of others who have tried the method that it should be adopted for all suitable cases.

The method of performing the operation of expression with this instrument is as follows :

The patient being fully etherized one of the lids is everted. In everting the upper lid I fold over the tarsal portion in the usual method of everting the lid, then seize the folded margin and withdraw it from the globe, at the same time everting it and fully exposing the upper cul-de-sac of the conjunctiva. The forceps are then thrust well into the cul-de-sac and as large a fold of the conjunctiva as possible is firmly grasped between the rolls. Firm pressure is then made and the rolls steadily withdrawn. As this is done the material composing the trachoma granules in the portion of the conjunctiva so grasped is seen to ooze out from the tissues on the rolls until the fold escapes from the forceps freed of this morbid material. A second portion of the conjunctiva is then grasped and similarly stripped, and this



is repeated throughout the conjunctival tract.

Especial care is to be given to the thorough cleansing of the parts of the membrane in the vicinity of the commissures, this being the most difficult part of the operation. The squeezing of the portion of the membrane lining the tarsal portion of the lids near their free margin is best accomplished by placing one roll on the conjunctival and one roll on the dermal surface of the lid, and drawing them up to the free margin of the lid.

In this way every portion of the conjunctiva is to be gone over two or three times until no more of the morbid exudate can be squeezed out. The conjunctiva is then to be cleansed of blood and exudate, and the after-treatment is to be directed to prevent undue reaction at first, and subsequently to prevent relapses.

The effect of this operation is at first to cause œdema and swelling of the lids, which gradually subside, leaving the favorable cases cured, with no more cicatricial contraction than was present when this treatment was resorted to. Indeed, in those cases in which there has occurred very marked cicatricial thickening and induration of the lid, the induration disappears entirely, and while there is later a tendency to its return the ultimate result appears to be a very marked permanent benefit.

The amount of benefit, however, is in general proportioned to the amount of the characteristic exudate present in and beneath the conjunctiva. Where this is the leading feature of the case the cure is immediate and, so far as I have been able to observe, permanent. But it is remarkable how much of this translucent jelly-like material can be pressed out of some thick indurated lids, that give very little evidence exteriorly of its presence.

In the favorable cases, those in which the granulations are well marked and the general induration and alteration of the deeper structures of the lid comparatively slight, a single rolling is sufficient. In the less favorable cases, those in which there is more induration and thickening, Dr. Knapp advises the free incision or scarification of the lid prior to rolling. In these cases, including the worst that I have encountered since resorting to this method of treatment, there was marked improvement after the operation, and it was repeated with still further improvement.

I have done the operation under cocaine anæsthesia, where the granulations were localized in a limited part of the conjunctiva, and the patient greatly preferred not to take ether. But the cases in which it is advisable to do it are quite exceptional, for without general anæsthesia the squeezing will not be thoroughly completed in every part of the conjunctiva, and it is only the thorough expression that produces the cures, which seem truly marvellous when compared with the results of older methods of treatment.

A word about the selection of the instrument: the essential point is that it should roll easily. This is first to be tested by seizing with it the fold of skin between the fingers, and noting if the rolls properly turn under very light pressure, and do not slide over the surface without turning. To ascertain if their motion is uniform grasp a piece of paper firmly between the rolls

and pull it out while firm pressure is maintained. If then the rolls are at all irregular in outline, or not properly centered, the movement will be found decidedly jerky instead of smooth and uniform as it should be. In using the instrument one must watch that it does not become clogged with blood and exudation and cease to roll, simply dragging over the tissues, for this does not as effectually empty them of the trachomatous matter, and is liable to cause tearing of the conjunctiva.

The corrugated rolls were adopted by Dr. Knapp, I believe, for the purpose of more certainly securing their rotation. I have also used smooth rollers with which it is essential to have the bearings work with perfect smoothness, but which, when they work perfectly, we would expect to empty the tissues more completely and with less bruising. It may be questioned, however, if a certain amount of bruising, enough to secure the free outflow of serous exudate, practically washing out the trachomatous matter as the tissue is gone over the second or third time, is not an important part of the treatment. So that on the whole the corrugated rollers are probably the better.

In conclusion, let me urge all who may have to deal with trachoma in its marked and characteristic manifestations, to put the patient under ether and roll the lids freely, squeezing out all the exudate possible and going over the whole conjunctiva two or three times.

Do not fear the apparent violence done the tissues. If the rolls turn properly, you cannot tear the conjunctiva; you will preserve all the epithelial surface there is to start with, and secure the minimum of cicatrical contraction. And in favorable cases a cure is accomplished by a single operation, sometimes without after-treatment.

CHLORIDE OF GOLD AND SODIUM IN PROGRESSIVE GENERAL PARALYSIS.

Boubila, Hadjes, and Cossa (*Annales Medico-Psychologiques,* January to April, 1892) state that this agent has no curative influence in general paralysis, but is useful in the early period, increasing the chances of remission, and in the later stages it tends to retard the fatal termination. Its administration is followed by an increase of red corpuscles and of body-weight.

A CASE OF OPERATION FOR CLEFT OF THE HARD AND THE SOFT PALATE, AS PERFORMED BY DR. R. W. WHITEHEAD.*

By GEO. HOMER GIBSON, M. D.,
DENVER.

On May 19, 1879, I witnessed an important and difficult operation for cleft of the hard and the soft palate by Dr. R. W. Whitehead. Frequently this operation results in failure, and the excuse is that the patient coughed or sneezed or vomited, or did something else and the stitches tore out. Dr. Whitehead emphatically stated before the operation, that if the muscles are completely cut and the sutures are properly placed and secured, that all the coughing and sneezing and vomiting will not cause the sutures to give away. I believe it. Those present at the operation were Dr. J. M. Norman, dentist, Dr. H. W. McLauthlin, myself, Miss McCann, nurse, and the father of the patient. The patient was a boy three years of age. In the performance of this operation the stages of procedure may be conveniently arranged as follows: (1) Gag. Dr. Whitehead's gag, as represented in Gross' Surgery and elsewhere. (2) Cutting the levator palati and the tensor palati muscles on each side with angular knives. (3) grasping the palato-pharyngeus and palato-glossus muscles on each side with Whitehead's forceps and cutting them with curved scissors. (4) Paring the edges of the cleft. (5) Making the side cuts and elevating the periosteum, guarding carefully against its detachment at the points of emergence of the superior or descending palatine arteries. (6) Passing the silver wire sutures and twisting as in Sim's operation for vesico-vaginal fistula. (7) Stuffing the side cuts with lint.

On the 14th day after the operation Dr. Whitehead kindly invited me to see the removal of the sutures. The union was complete throughout. The cleft in this case measured in its antero-posterior direction 1¼ inches, and transversely nearly ½ inch. For its closure it required six silver wire sutures and two silk sutures, the last two being placed near the tip of

*Read before the Colorado State Medical Society, June 24, 1892.

the uvula. The main requisite for the surgeon in this operation is to bring to his aid a perfect knowledge of its anatomy, including the relations of parts, and a full appreciation of the action of the muscles. It is an operation founded on principles strictly scientific, and is one of the most difficult in the whole range of surgery. Anything less than the most painstaking care of its details will result in failure. Yet a first attempt may be entirely successful, as in Dr. M. Storr's case, related in a letter to Dr. Whitehead, which he kindly showed me, and in which letter Dr. Storr states that he was opposed by the whole of the surgical staff of the Hartford Hospital and Dr. Storr "made one operation and got entire union." Such Dr. Whitehead says he believes will be the result in the hands of any painstaking surgeon of fair ability, who has qualified himself by a sufficient practical study of the anatomy of the muscles and other parts.

LOW TEMPERATURE AND PHTHISIS.

Of all devices which, since its discovery, have been attempted to destroy the bacillus tuberculosis in the body none, perhaps, is more irksome—and, indeed, barbarous—than that of keeping the unfortunate victim of phthisis in a cold temperature, as if the normal temperature of the blood were in the very least affected by that of the atmosphere. Nevertheless, such views are held by the Russian physicians who have the care of the health of the Czar's second son, the Grand Duke George, who developed symptoms of pulmonary disease when on his Indian tour. He has, we learn, been spending the winter at Abbas-Tuman, in the Caucasus, dwelling in barely furnished rooms, with little bedding, only a very moderate fire, and the windows continuously open. No doubt the pure mountain air is the chief agent in the effort to keep the disease in abeyance, and not the cold, which has been so severe that his Royal Highness's attendants have suffered greatly from it; and we trust the hopes of the physicians that the Grand Duke will in two years' time have completely recovery may be realized. Very likely he would have done equally well at Davos or St. Moritz, without a sacrifice of that comfort which phthisical patients so much need.—*Lancet.*

CASE OF ECZEMA VENOUS VARAIX, WITH TREATMENT.

By A. O. STIMPSON, M. D., C. M.,
THOMPSON, PA.

J. S. (an old soldier) has been troubled with eczema venous varaix ever since he was in the army, 1864 and 1865. Since that time his lower extremities have been more or less swollen and painful especially when he was obliged to be on his feet. He is a hotel keeper by occupation, and no doubt is a liberal sampler of his own liquid refreshments. He is a man of 5 feet 11½ inches, and weighs about 187 pounds, a man of very irregular habits, an Englishman and of apoplectic tendencies. I have known the man for twelve or fifteen years but have never been called upon to treat him until June 14th. At 5 o'clock A. M. on June 14th, 1892, I was called up in haste to attend him. The messenger informed me that he was bleeding profusely from a ruptured artery on his leg. I hurried up to the house and found him lying back on the sofa in a semi-exhausted condition from the hæmorrhage which had indeed been profuse, as pools of blood lay about the floor where he had sat in the kitchen. On examination I found his left leg in a condition of chronic eczema complicated with large varicose veins. He informs me that within the past six or seven years he has suffered occasionally from hæmorrhage, but that it has always been easily controlled by simple bandaging. I found on examination that the hæmorrhage proceeded from the external saphenous vein, as if an artery had been cut across. I put on a rubber ligature above the knee, washed the leg and wound, then took antiseptic cotton saturated it with tinct. of iron and packed the small opening with it until the hæmorrhage had stopped. Then I made a firm compress of carbolated cotton, saturated it with a forty per cent. carbolic acid solution, then put on a firm bandage of muslin from the toes up to three inches above the knee. I am confident that there will be no further trouble as I put him on a constitutional diet with eight drops tinct. of iron and three drops fluid ex. ergot, to be taken every four hours. The cotton bandage is to kept on five days and then a Martin's rubber bandage to be constantly worn. Also, after the

five days he is to take five drops of Fowler's solution of arsenic one half hour after meals, *ter in die,* in order to cure his eczema.

EFFECT OF BITTERS ON GASTRIC MOVEMENTS.

Dr. Paul Terray of Buda-Pesth has published on account of some investigations he has recently made, with the view of determining the effect of various bitters on the movements of the stomach. For this purpose he employed the stomachs of dogs taken from the body immediately after the animal had been killed by severance of the crevical spinal cord. Both orifices of the stomach were then tied and the organ was immersed in a bath of water which was at the temperature of the living body and contained in solution 0.75 per cent. of common salt. Where no drugs had been introduced the automatic movements continued for about three-quarters of an hour, after which time signs of death began to appear in star-shaped contractions; and in another half hour mechanical stimuli ceased to produce any response, irritability being subsequently lost, first to cold water, then to the galvanic current, and lastly to hot water. When the animal was kept on a restricted diet for two days, and a quarter of an hour before being killed a dose was introduced into the stomach of some bitter which acts on the peripheral automatic centres of the stomach, the movements were stronger, more rapid, and more persistent—the most powerful drug being gentian, and after that cetrarin and condurangin; then there came taraxacum, quinine, and lastly quassia. The irritability of the stomach to mechanical stimuli was increased by gentian, taraxacum, quassia, strychnine, and columbine. Small doses of absinthin diminished the irritability, and large doses arrested it altogether. Columbine and strychnine increased the irritability until persistent general contractions were induced. Picrotoxin produced no effect on the contractions, while cetrarin not only set up increased movement in the stomach, but produced a similar effect upon thei ntestinal movements. From a therapeutic point of view, therefore, it appears that in atonic conditions and moderate dilatation bitters may be given with advantage. Cetrarin, it may be well to remark, acts as an aperient in addition to its effect upon the stomach.—*Lancet.*

Society Reports.

MEDICO-CHIRURGICAL SOCIETY, OF LOUISVILLE.

Stated Meeting July 24, 1892.

Dr. Thos. L. McDermott, Vice-President, in the Chair.

THE REMOVAL OF ENLARGED LYMPHATIC GLANDS.

Dr. W. L. Rodman: This young man is a patient that I operated on six weeks ago to-day and reported the case the same night at meeting of the Medico-Chirurgical Society, at the Pendennis Club. He had a tumor in the inguinal region caused by enlarged glands, the mass being as large as a duck egg. I cut down to the glands and dissected them all out. Dr. McDermott assisted in the operation. The operation was done on Friday afternoon and he went to work the following Wednesday. It was one of these idiopathic enlargements; patient has had no venereal disease. I removed eight or ten very much enlarged glands, cutting very nearly down to the femoral artery. By the operation I think I saved this patient at least six weeks suffering, and believe that this is the best way to treat these enlarged glands.

Dr. C. Skinner: I think this case illustrates a point, and proves that these cases all ought to be operated upon in this way. There is no doubt about such cases always going on to suppuration. I believe it is better to remove the glands in the start rather than allow suppuration to take place and then open them. The results in Dr. Rodman's case seem to be everything that could be wished.

Dr. W. L. Rodman: When the operation was performed, the patient was very much run-down in health. He has gained at least ten pounds since being operated upon six weeks ago.

Dr. Turner Anderson: I would like to ask about the scar that is so plainly visible now; will it not disappear after a while?

Dr. W. L. Rodman: I think it will go away. This scar would not have been as marked as it is now, if I had not kept the wound packed. I did not want it to heal too soon.

Dr. Turner Anderson: What do you think will be the effect upon the lymphatic structures upon which these glands act situated below? That is, will it interfere with their functions in any way?

Dr. W. L. Rodman: I do not see how it would interfere with the channels; the lymph gets back in some way without any doubt. The deeper lymph glands were not removed.

Dr. T. L. McDermott: There are a great many glands in this region, and I do not think it is reasonable to assume that they were all removed.

Dr. W. L. Rodman: I removed all the superficial glands.

Dr. S. G. Dabney: In this connection, I would like to ask one or two questions about enlarged isolated lymphatic glands. I saw a case the other day, a young lady, having enlarged glands just back of each ear. There seemed to be no cause for this condition; the lady was otherwise in perfect health. There was no involvment of the cervical glands, but simply the glands just back of each ear were enlarged and quite tender. I would like to ask if there is any reasonable explanation of the appearance of these isolated enlarged lymphatic glands, and what the treatment should be. Also whether the treatment of iodine ointment is of any value.

Dr. C. Skinner: I have always found that we can trace this down to some hereditary trouble; some specific lymphatic engorgement. Cases of this character that have come under my observation, I have put on treatment consisting of a preparation containing bichloride of mercury. They may feel and look all right, but the lymphatic system is out of order, the circulation bad, and the treatment should be with a view of improving these conditions and then the enlargements will disappear.

Dr. W. L. Rodman: I would like to ask if Dr. Dabney's patient had any bad teeth.

Dr. S. G. Dabney: That is a point I had not thought of, and made no inquiries concerning the teeth.

Dr. Turner Anderson: Enlargement of the posterior cervical glands is not at all unusual, occurring in an acute form. In the last epidemic of German measles this symptom was present; it was present in nearly all cases; an enlargement of the chain of glands of the neck was one of the prominent symptoms. I do not think we have any reason to believe that there is anything specific about these enlargements. I believe it is simply acute adenitis, catarrhal in all probability in a great many cases. My experience is that these enlargements go down without any treatment. They occur just as we sometimes see enlargements of the inguinal glands occur in an epidemic way. I saw an epidemic of inguinal adenitis several years ago, a great many cases presenting themselves. We are constantly seeing cases of idiopathic inguinal adenitis.

Dr. T. L. McDermott: Concerning the removal of these enlarged inguinal glands—this is a matter that is not pushed far enough by the medical profession. I think that the doctors in ordinary practice, who meet most of these cases, instead of suggesting that they be left to the processes of nature, allowed to suppurate and the abscesses finally be opened, allowed to take their course, they should advise the early removal of all these enlarged glands. People as a rule are not educated to the idea that this is the proper treatment. This young man may be the means of getting a half dozen of his friends to submit to this operation. I believe that the profession ought to take more cognizance of these cases and advocate operation more than they do, and educate people to this idea. The result in Dr. Rodman's case seems to have been all that anyone could wish. I am satisfied if the operation had not been done, the patient would have been coming to my office two or three months, would probably have spent two or three weeks in bed and had the enlargement lanced with a good deal of pain, etc. I think on the plea of economy it would be cheaper for patients to have these glands removed. I believe that eneucleation is the only proper treatment, and we should try to educate people to have this done.

Dr. W. L. Rodman: I have been operating in this manner for two or three years.

Dr. C. Skinner: While on the subject of glands, I will relate a case. Some time ago a gentleman brought his boy, about seven years of age, to see me. The whole family history is phthisical, one sister of the mother having died of this disease, and the mother having had two or three

alarming hæmorrhages. This child had an enlargement of the sub-maxillary lymphatic in the right lower jaw midway between the angle and the symphysis, which was very tender on pressure. He had been to see a dentist and had one tooth extracted, another tooth in the vicinity appeared to me to be loose. I gave it as my opinion that it was one of two things, either tuberculous glands, or an epulis, rather inclining to the view that it was a tuberculous gland. I asked him to let some one else see it. He took the child to another physician, an examination was made and the physician advised them to wait, that he did not think the bone was involved at all, and let it suppurate then open and scrape it out. I had advised immediate removal of the gland. I want to ask the members of the Society present which of the two procedures would have been preferable, that is granting that it was a tuberculous gland, would it not have been better to have removed the sac and gotten rid of all the tubercle bacilli in order to prevent further infection of the system, rather than to let it suppurate ?

Dr. Turner Anderson: Was the cavity of the tooth still open ?

Dr. Skinner: The effects of extraction had disappeared, but another tooth seemed to be loose. The child passed out of my hands, and I learned afterward that this gland was scraped. The family history pointed strongly toward tubercular infection.

Dr. W. L. Rodman: I should judge from what Dr. Skinner has said about the case and the history, that it was most likely of a tuberculous nature. I fully agree with him that the only thing to have done was to dissect out this chain of large glands.

Dr. Turner Anderson: How long had the large glands existed, the loose tooth, etc. ?

Dr. Skinner: I think about four weeks.

Dr. Turner Anderson: I do not think I would have advised any operative procedure in such a case. It is doubtful if suppuration would have occurred. With a history of only a few weeks I think it would have been very active surgery, and believe I would have waited a little longer before advising an operation.

Dr. W. L. Rodman: It is only a question as to whether you open before suppuration takes place. It is a very easy matter to remove those glands by making an incision along the inner angle of the jaw. I have never seen an acute abscess form in that situation, and believe they are all tubercular.

Dr. T. L. McDermott: A little fellow about four years old was brought into my office some time ago having such an enlargement on the bone. I treated this with warm applications and it disappeared in ten days or two weeks without suppuration. I think our action in such cases should depend a great deal upon the character of the infection, if it seems to be spreading increasing rapidly, or if any symptoms point toward softening, then I believe radical measures should be adopted.

MENINGITIS.

Dr. S. G. Dabney: I reported a case to the Society some months ago, of a child who had paralysis of some ocular muscles of the right side, the external rectus muscles of the right eye and partial paralysis of the same side of the body, both upper and lower extremities. I reported at the time that the history was the child had sustained a fall, also had an attack of meningitis, both of which, however, were so long before the appearance of the paralysis as to have hardly caused the lesion. I merely want to say that the child has since died. I have never seen the patient since, but I learn it died of meningitis.

ACQUIRED HYDROCEPHALUS.

Dr. Turner Anderson: I would like to continue report of a case:—The child (clinical case) that I presented at the last meeting of this Society, suffering from acquired hydrocephalus, died a few days ago. The man I exhibited having an irregular pulse is now anasarcous, has a very well marked tumor in the epigastric region, which seems to be the left lobe of the liver. Still has disturbed circulation, and is simply growing worse all the time.

PECULIAR CASE OF LAPAROTOMY.

Dr. C. Skinner: I want to mention a peculiar case of laparotomy performed at the city hospital a short time since for double ovarian cyst. One cyst was about the size of a large cocoanut, and was absolutely without a pedicle. I never saw anything like it, the cyst was only fastened by adhesions, I separated adhesion after

adhesion expecting of course to find a pedicle, but when all the adhesions were broken the tumor simply fell out upon the table. The other cyst was smaller, about the size of a goose egg, lower down and more firm than the larger one. This was tied off and removed. The large cyst having no pedicle, I suppose had simply lived from the adhesions which had sprung up around it. The woman has done well, has had no fever.

DR. TURNER ANDERSON: What was the condition of the ovary on the side having the large cyst?

DR. C. SKINNER: I could not find the ovary; it was probably lost in the mass alongside the tube.

DR. T. S. BULLOCK: I saw this case and was very much surprised that there was no pedicle. The tumor was lifted up to the abdominal wall and its own weight broke the attachments and it fell on the table. I never saw anything like it.

DR. TURNER ANDERSON: Did you examine the structures after the cyst was removed?

DR. C. SKINNER: Yes, everything was examined carefully.

DR. TURNER ANDERSON: Might it not have been a par-ovarian cyst?

DR. C. SKINNER: Possibly, but the ovary could not be found. The other ovary was found, the cyst on that side not having gotten so large.

DR. W. L. RODMAN: What was the character of the fluid in the cysts?

DR. C. SKINNER: It was about the color of urine, about like ordinary serum.

DR. T. S. BULLOCK: I noticed Dr. Skinner tie something which he supposed was the pedicle of the large cyst, but afterward found it was not.

TREATMENT OF HICCOUGH.

Hiccough is sometimes a very troublesome symptom, and in some cases may be difficult to overcome. Leloir, in a case of a child twelve years old suffering from persistent hiccough, applied digital pressure for three minutes to the left phrenic, between the two attachments of the sterno-mastoid; the hiccough stopped and did not recur. He has since used the method in a large number of cases, and always with success; in some cases pressure for a few seconds has been sufficient, in others a few minutes.

Selected Formulæ.

SUBSTITUTE FOR OPIATES.

Dr. Portier (*La Semaine Médicale*, No. 19, 1892) recommends the following as a substitute for the preparations of opium:

℞ Hydrochlorate of cocaine.....cgms. 50.
Phenacetin.....gms. 1.5.
Exalgine.....cgms. 50.
Salicylic acid.....gm. 1.
Divide into ten powders. Take one powder every two or three hours until the pain ceases.

AN IDEAL DRESSING FOR ABDOMINAL WOUNDS.

Kelly (*Am. Jour. of Obstet.*, December, 1891) states that an ideal dressing should be a paste, which would harden quickly—thin, flexible, transparent, impenetrable, which would hermetically seal the wound from external septic invasion.

After closure of the incision, the skin, the line of the wound, and the sutures are dried, and two layers of sterilized gauze or cheese-cloth, large enough to project five to ten centimetres (two to four inches) beyond the incision on all sides, laid on the skin. This is saturated with the following adhesive mixture, which is evenly distributed over the whole surface:

℞ Squibb's ether, or washed ether, and alcohol, absolute, equal parts.
Bichloride of mercury (Merck's recryst.), enough to make the solution $\frac{1}{1000}$.
(Anthony's) snowy cotton, enough to make a syrupy consistence, adding in small pieces, stirring.

As soon as this is poured over the wound evaporation begins to take place at once, and the celluloidin hardens, gumming the gauze fast to the skin. To avoid delay in waiting for this to grow quite hard, and to prevent adhesion to the cotton applied above it, the whole surface is freely dusted over with a finely powdered mixture of iodoform and boric acid:

℞ Pulveris iodoformi, 4 grammes or 1 drachm.
Acidi borici, 28 grammes or 7 drachms.
M.—Exactissime. Sig.—Dust freely on wound.

This powder is of itself an invaluable protective. I use it constantly in obstetric cases, separating the labia and throwing it into the vagina, where it acts as a guard to the vaginal outlet against septic invasion from without.

The wound thus sealed with celluloidin gauze may be left untouched for a week or more, when the dressing should be softened with water, or more rapidly with ether, the gauze lifted off and the stitches taken out.

THE

MEDICAL and SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

DIRECT COMMUNICATIONS TO

Leading Articles.

INSANITY AND CRIMINAL RESPONSIBILITY.

The term "medical expert" as used in the criminal courts is one which frequently tends to make the profession the laughing stock of the public at large, and it has become a by-word that such testimony is a reproach rather than a credit to the profession. A noted lawyer upon being asked what in his consideration was the best life preserver, answered promptly, insanity. This is true enough, thanks to the medical expert. It must indeed be anything but comforting to those members of the profession who keenly feel its responsibilities to the public that so large a number of murderers and other criminals are not only saved from a just punishment through the endeavors of these experts, but again thrust upon the public to be a constant menace to society.

This important subject may be viewed from two points: First the validity of the so-called expert testimony; second, the value of insanity or mental peculiarities or weaknesses as an excuse for crime.

The first point is one that can only be briefly touched upon in this article. The term "medical expert" is one that has absolutely no value and frequently no meaning. Anyone having the title Doctor of Medicine can claim to be a medical expert. In America the student who attains his degree with little or no preliminary education and after a few months' study, and the student who has passed brilliant preliminary examinations and obtained his degree after a four or five years' course in our great medical schools, both arrive at the same end as far as the public are concerned—they are "doctors" and here the matter ends. The title of "medical expert" may be claimed by one as well as the other—and more likely by the former than the latter. That criminal lawyers make active use of this vast uneven-

ness is only too patent, and the mass of absurdly contradictory and untruthful evidence frequently elucidated when such expertism is called into requisition redounds to the great discredit of our honorable profession, and renders the value of evidence from reliable sources almost as questionable as that obtained from unworthy witnesses.

Naturally there are unprincipled men in the medical profession as in every walk of life, but a vast amount of the worthless evidence given in court by medical experts is the result of the deliberate suppresion of the truth or of absolute ignorance. To be an expert on insanity means a life-long experience with such cases, and only those who have made mental and nervous diseases a specialty should be permitted to give evidence as experts.

But to turn to the other point at issue—Is insanity or mental peculiarity and weakness a valid excuse for crime?

The Latin poet has justly said that *ira furor brevis est*, and criminal lawyers making use of the theory are content to prove that their clients were insane only at the moment of the commission of the crime, and therefore irresponsible. A glance at the results of coroners' inquests in the case of suicide reveals the great predominance of the verdict "*felo de se* while laboring under temporary insanity."

Indeed, some authorities go so far as to say that no one in the possession of their mental faculties would voluntarily take their own lives. Would not a similar contention be applicable in case of murder and other revolting crimes? Again, in cases where the criminal is evidently of a very low mental calibre, in whom bestiality and brutality are inherent traits, is it justice to credit him with the same amount of moral responsibility as an educated or sane man?

All this is theorizing, but theorizing that is made active use of in our criminal courts, and theorizing which, to the disgrace of the so-called medical expert, turns out yearly from behind the bars a large number of dangerous criminals.

In the enforcement of the extreme penalties of the law, two points are held in view: First, the example to others; second, the public welfare.

In what manner the public welfare is to be conserved by the acquittal of the criminal insane or criminally irresponsible is not apparent. If such an acquittal meant a confinement for life or until the individual's mental condition had become such that he was no longer a menace to society, it would be another thing. It is only too common that when such criminals are subjected to confinement it is but a short time before they are liberated, but their mental condition unimproved.

The case of Deeming which recently engaged the attention of the civilized world is that of a man who has made murder a pastime—murder in its most brutal and barbarous form. Not only murder, but theft, forgery and a whole list of other crimes. A man in middle life, and until his arrest able to earn for himself a good livelihood; successfully act a series of different parts; travel extensively; court, marry, and become a father. For years he succeeded in adroitly covering up his atrocious deeds. He was finally brought to justice, his lawyer spoke of him as "the abnormal offspring of a mother's womb," medical experts came to his rescue and endeavored to prove by various facts that he was morally irresponsible for the crimes he committed. The question is, should such a condition justify acquittal. In aiding the acquittal of such monsters our medical experts are confronted by a most grave responsibility, which we fear is in many cases unrecognized. To declare a man mentally deficient, morally debased, or intellectually wanting, and to prove that his mental organization is of low calibre, his moral instinct dulled through disease or inheritance is well enough, but

to assert the absence of moral responsibility and the justifiability of acquittal is a step too far.

Book Reviews.

HOW TO FEEL THE PULSE AND WHAT TO FEEL IN IT. By Wm. Ewart, M. D., Cantab., F. R. C. P. Physician to St. George's Hospital, London, etc., etc. New York: William Wood & Co., 1892.

This little book deals with a subject which is at the present time very much slighted. Consequently we have perused its pages with a considerable degree of interest.

The author coufines himself strictly to elementary facts, and does not burden the text with statements of the various pathological conditions in which certain variations in the pulse-wave exist. The principles which govern the study of the pulse are fully but simply set forth, and brief neccessary reference is made to the more common diseases which markedly influence it.

Admirable features of the book are its brevity, the bold headings, and systematic subdivision of the subject into very appropriate parts.

The classical forms of irregular pulse receive proper attention.

It is a most excellent work of its kind, and will be found profitable reading for both student and practitioner.

DISEASES OF THE NERVOUS SYSTEM. By Jerome R. Bauduy, M. D., LL.D., Professor of Diseases of the Mind and Nervous System and of Medical Jurisprudence, Missouri Medical College, St. Louis. Philadelphia: J. B. Lippincott Co., 1892.

We are led from the title of this book to expect a more or less complete treatise on nervous diseases. We are told in the preface that the work is the product of "a long, studious and extensive experience." In fact, it consists of long quotations, with an occasional interpolated paragraph or page which is usually of far less value than the borrowed matter. It is, of course, quite out of the question to write an entirely original work on this subject, but the reader can justly demand that the author shall give him something more than a scrap book of other men's ideas. However, judging from the author's interpolations, we are extremely thankful that the borrowed matter is so voluminous.

Eighty pages are devoted to a subject which may or may not have a pathological existence, viz. cerebral anæmia and hyperæmia. Twelve pages are devoted to the certainly not vitally important question of neomembranes of the dura mater. Inflammatory diseases of the membranes are discussed.

The above includes the entire contents of a book purporting to deal with diseases of the nervous system.

The polypharmic tendencies and therapeutic faith of the author are shown in his combination of three varieties of pepsin in one prescription.

He states that "anatomical detail and physiological discussion have been thought inadmissible," yet he gravely tells us that the vaso-motor nerves go to the elastic coats of the arteries, and makes no mention of the muscular coat the true seat of distribution.

In conclusion, we must admit that this is one of the poorest books we have ever read.

INFECTIOUS MULTIPLE NEURITIS FOLLOWING FACIAL ERYSIPELAS.

Leu, (*Charité-Annalen*,) reports the case of a patient who came under his observation in the hospital suffering with some slight symptoms of neuritis. The accession of the disease had taken place immediately on convalescence from facial erysipelas and had appeared to be a mild attack of articular rheumatism. There was only a slight paræsthesia of the lower limbs. Following this came a sense of pressure in the main nerve trunks, with disappearance of the patellar and cremasteric reflexes. There was also marked subjective and objective sensory disturbances, with impairment of electrical reaction of the muscles and nerves to both currents, which eventually gave the reaction of degeneration. Atrophic changes took place rapidly. The height of the fever was in no proportion to the pulse acceleration. The breathing was very difficult in consequence of deficient innervation of the muscles of respiration. There was a peculiar desquamation of the skin of the the extremities, with excessive hyperidrosis of the entire body and a miliary exanthemata over the breast, abdomen and back. Albumin was present in the urine. The spleen was distinctly enlarged.

Periscope.

THERAPEUTICS.

A NEW BORIC ACID PREPARATION IN THE TREATMENT OF CHRONIC PURULENT OTITIS MEDIA.

Dr. Max Janicke, of Görlitz, recommends the use of a neutral borate or tetraborate of soda, in the treatment of chronic purulent otitis media. This preparation is obtained by heating equal parts of boric acid, borax and water. Upon cooling, the precipitate will be found to be neutral in reaction. It is soluble to the extent of 16 per cent. in water at the ordinary temperature of the room, while in boiling water it is soluble to an almost unlimited extent. This salt possesses the valuable peculiarity that, unlike other salts, it does not precipitate from its hot concentrated solution immediately upon cooling. Precipitation does not occur for some time after cooling, so that solutions of 50 per cent. may be used in the drum-cavity. Thus, a large quantity of an antiseptic material can be introduced into and kept in the drum-cavity for a long time. Once in twenty-four hours is often enough to apply the solution in cases of moderate discharge, while in slight discharges less frequently will answer. The neutral borate of sodium is extremely mild and unirritating. After the use of the above-named solution in cases of large perforation in a total of the membrana tympani, some of the same neutral salt may be blown into the ear.—*Archiv fur Ohrenheilkunde,* vol. xxxii pp. 14-24.

OXYGEN INHALATIONS.

In an interesting contribution to the *Chicago Médical Recorder,* Dr. N. S. Davis, Jr., remarks:

Briefly it can be said that the indication for oxygen inhalations in respiratory affections is cyanosis. It can be expected to give prompt and very great relief in acute dyspnœa with cynanosis; such as often accompanies asthma, acute capillary bronchitis, broncho pneumonia, croupous pneumonia, œdema of the lungs, or pneumothorax. Usually œdema of the lungs develops at a time when permanent relief is impossible, as the patient is already too much enfeebled to combat the primary malady, but the best results can be expected when œdema threatens or develops early while the heart and respiratory muscles are still fairly vigorous. Good results can be hoped for in a self-limited-disease of short duration such as croupous pneumonia, for by oxygen sometimes life can be maintained until the crisis in the malady is past. Unfortunately, as the reports of its employment in pneumonia show, when cynosis and œdema develop, the case rarely terminates by crisis, but is prolonged. As digitalis finally fails to stimulate a flagging heart that is extensively degenerated so in pneumonia, oxygen, though signally efficient at first, finally fails to maintain a good degree of oxygenation of the blood.

A degree of greater well-being can be expected even in chronic dyspnœa, but it will be less marked than in acute.

TREATMENT OF SYPHILIS BY EUROPHEN.

Following Eichhoff, Petersen, etc., Dr. Gaudin had experimented with europhen (iodide of isobutylorthocresol) in the treatment of syphilis. He employs a solution in oil in the proportion of five grains of europhen for a hundred cubic centimeters of oil of sweet almonds, injecting up to five cubic centimeters at a time of this solution by means of the Burlureaux injector. There is a great advantage in employing oil as a vehicle in europhen, in fact, it dissolves a large quantity of the drug, and it is well known that oil, employed as a subcutaneous injection, is not painful and does not produce abscesses of the skin. The conclusions of the author are as follows: The subcutaneous injections of europhen in oil are well borne, although they are at times a little painful; they never provoke accidents, either local or general; they constantly ameliorate the syphilitic manifestations of the tertiary stage, although he cannot state that he has obtained by this means complete cures; they seem to act as quickly and as well as solutions of gray oil or of sublimate; they can thus be employed when we wish to produce a prompt and energetic action in cases of severe symptoms. However, the author recognizes the fact that these injections have little effect on the secondary manifestations in course of evolution. We may thus ask if we can really count upon the efficacy of this treatment in syphilis.

MECHANICAL TREATMENT OF ASTHMA.

Dr. Goebel treats asthma by rapping the posterior portion of the chest quite violently, until the entire thorax is set into rapid vibration. This improves the circulation and also influences favorably the emphysema upon which the disease is based, stimulates the atrophic vesicles, and thus indirectly betters the nutrition of the lung. Although the writer has used this method in but a small number of cases, he feels that he is justified in bringing it to the notice of the profession, as he has obtained such good results in the cases treated.

EUPHORBIA PILULIGERA IN HAY ASTHMA.

E. S. Blair (*Therap. Gaz.*, March, 1892) records a troublesome case of hay asthma in which administration of a fluid extract of euphorbia piluligera gave the happiest results. The patient was a child of 10 years, who every August suffered from attacks of the disease. While administration of the usual remedies altogether failed to procure relief, the new drug was rapidly successful, not only against the primary attack, but in cutting short any recurrence of the affection. The same writer also mentions terebene as a useful drug under similar circumstances.—*Brit. Med. Jour.*

THE USE OF DIGITALIS IN AORTIC DISEASE.

In the *British Medical Journal*, 1892, No. 1628, p. 542, Dr. Alfred G. Barrs, after a very thoughtful discussion, concludes:

1. In all cases of valvular disease the chief desideratum in regard to the heart itself is the condition of the cardiac chambers in respect to dilatation and hypertrophy.
2. That the presence of symptoms in cardiac disease always means failure of compensation.
3. That the condition described as over-hypertrophy or over-compensation does not exist.
4. That the dangers in aortic disease arise from the same cause as the dangers in mitral disease, namely, failure of the compensation—that is, failure of the ventricular muscle to overcome the ever-increasing work put upon it.
5. That if digitalis is safe and beneficial in mitral disease, it is equally so in aortic disease.

Dr. Seymour Taylor argues from clinical experience that there is little or no comparison between the action of the aortic valve and that of the mitral, and that the theories advanced in the preceding paper are not orthodox (*British Medical Journal*, (1892, No. 1631, p. 705).—*Amer. Jour. Med. Sci.*

CHLORIDE OF ETHYL.

Delmis (*Gaz. d. Hôp.*, March 31st, 1892) calls attention to the advantages of chloride of ethyl as a local anæsthetic for minor surgical operations not lasting longer than one or two minutes. The best method of applying the anæsthetic is by using the glass tubes introduced by Monnet, of Lyons. These tubes are filled with the liquid, and have a capillary opening hermetically sealed. All that is necessary is to break off the point of the tube, and direct it on the part to be made insensitive; the heat of the hand holding the tube is sufficient to vaporize the liquid.

THE TOXIC ACTION OF IRON ON THE ANIMAL ORGANISM.

Dr. I. Wojtaszek, from his experiments on animals in this direction, arrives at the conclusion that iron may act toxically only after its injection into the blood or under the skin. The toxic action is manifested by paralysis of the central nervous system, which is preceded by a temporary irritation. Death follows from asphyxia, as the result of paralysis of the respiratory centre. If iron is injected under the skin for a longer time, changes of an inflammatory character appear in the kidneys, and the author admits *per analogiam* the same changes in man. The internal administration of neutral preparations of iron occasions no symptoms of poisoning. Furthermore, the author is convinced that iron does not act upon the muscular tissues of the heart, and hæmorrhage occurring as if from its abuse, may depend, as Scherff asserts, not on greatly augmented arterial pressure, but on the return of the pressure to the normal state after the removal of the disease. Finally, the author remarks that hypodermatic injections very often occasion abscesses or inflammation of the connective tissue. He believes that the best preparations of iron are its com-

bination with the organic acids, because they are easily absorbed and do not occasion local changes in the digestive tract. For hypodermic injections he recommends ferrum pyrophosphoricum cum natrio citrico, and advises physicians to abandon the use of iron.—*Przeglad Lekarski*, Nos. 5 to 7, 1892,

THE TREATMENT OF OBSTINATE HICCOUGH.

It is doubtless perfectly true that the treatment of hiccough has not received much notice at the hands of the writers of text-books in this country. But the reason of this probably is that the symptom seldom attains to any serious proportions in this part of the world, so as to call for relief by the medical man in attendance. When, however, hiccough acquires an obstinate persistency, for the relief of which therapeutic aid is urgently needed, difficulties may be met with. A case in point is recorded in an Indian contemporary, where a retired officer, aged 76, who had been suffering from acute congestion of the liver became affected with obstinate hiccough, which set in as a most alarming and distressing symptom. Everything was tried in the way of drug treatment which could be suggested, but without avail. One day, however, some beef tea was taken, which incidentally caused the patient to vomit. For a time, in consequence of this, the hiccough was relieved; whereupon the practitioner determined to try an injection of apomorphine, and the result was that vomiting was produced, and the hiccough ceased permanently. Altogether the symptoms persisted incessantly for seventy-two hours, and caused much distress to the patient. Physostigma has been recommended as useful in these cases.—*Med. Press.*

ELECTROTHERAPEUTICS AND SUGGESTION THERAPEUTICS.

Mæbius claims that in 80 per cent. of all cases in which its action seems beneficial, this is due to its psychical, not its physical influence. Eulenberg (*Berlin. Klin. Wochenschr.*, Nos. 8 and 9, 1892) has undertaken to answer M.'s objections. In regard to the first point, that it has not been proven that electricity has a curative action upon organic paralysis, and that paralyses which improve under electricity would do so without it. Eulenberg points out that the recovery would be slower and not so complete, and asks whether the results obtained in paralyzed animals are due to suggestion. Mœbius' second and third theses are: that many functional troubles are relieved by electricity and also by suggestion, ergo: electricity acts by influencing the mind only. Eulenberg points out that these troubles are also relieved by morphine, atrophine, bromides or arsenic, and asks whether these too, act psychically, as well as massage and hydro-therapy. The fifth thesis declares that the extreme variation in action of electricity, both galvanic and faradic, can only be explained by assuming that it acts by influencing the mind of the patient. Eulenberg points out that we are dealing with vital processes and not with dead material, and that we cannot predict the action of such well-known drugs as morphine or chloral in all cases. While combating Mœbius' heresy in regard to the action of electricity, Eulenberg admits that Mœbius has done a good work in pointing out the uses and benefits of psychotherapy, and calls attention to the facts that electricity, as administered by the non-expert physician, is liable to be the failure that Mœbius has described, and that general knowledge of its therapeutic application has not kept pace with the distribution and improvement of the electric armamentarium.

TREATMENT OF NEURASTHENIA.

Dr. R. Perdigo, of Barcelona, has taken up the modern treatment of neurasthenia very thoroughly in the *Gaceta médica catalana*, November and December, 1891, numbers. In speaking of general massage, the writer believes it unless in those cases which are well nourished, because it predisposes to an exaggerated morbid excitability. In the asthenic cases, when carried out with care and prudence by skilled masseurs, good results may be expected. the circulation is improved, the nutritive processes hastened, disintegration of elements unfavorable and useless to the organism is brought about, and as results the nervous system is stimulated, the appetite is improved and the general condition of the patient is bettered. The author pays homage to American writers on this subject, and from his many references must have been a close observer of America neurology.

ATROPINE AS A HÆMOSTATIC.

Strizover (*Meditz. Obozrenië*, No. 6, 1892) reports five cases of profuse hæmorrhage (1 of metrorrhagia after early abortion, 3 flooding of obscure origin, and 1 phthisical hæmoptysis) cut short by hypodermic injections of one-sixtieth of a grain of atropine. In the abortion case—woman, aged 26,w ith aortic regurgitation—digitalis internally, cold to the cardiac region, plugging the vagina with salicylic cotton-wool, and intrauterine injections of tincture of iodine and, later on, of perchloride of iron had previouly been tried in vain. After three injections of atropine—one in the evening, another three hours later, and the third in the morning—the hæmorrhage ceased, the patient making a good recovery. A. N. Dmitrïeff (*Vratch*, No. 50, 1891) relates two cases in which atropine acted well as a hæmostatic. One was that of metrorrhagia of a fortnight's standing, the patient having been previously vainly treated by ergot internally, plugging, etc. The bleeding completely ceased after four injections of $\frac{1}{100}$-grain of atropine given twice daily. The other patient was suffering from very severe menorrhagia. Persistent internal administration of ergot and hydrastis canadensis, ice locally, etc., having failed, a syringeful of an atropine solution (0.003 gramme of the sulphate to 10.0 aq. dest.) was injected under the skin. A marked general improvement followed half an hour later. After a second dose, five hours later, the bleeding considerably lessened, and after the third and last (twelve hours subsequently) ceased altogether. Only trifling dilatation of the pupils was noticed in the patients.—*Brit. Med. Jour.*

MEDICINE.

RECOVERY FROM LOCOMOTOR ATAXIA.

Dr. Cronyn relates a case of locomotor ataxia in the second stage with cure following an attack of erysipelas of the face and head. The man continued under treatment about a year without benefit, when the attack of erysipelas set in after exposure to cold. He was violently delirious about four days. After recovery from erysipelas it was noticed he could walk without a cane. There was no ataxia. He remained well and in the hospital for three years; was exhibited to students, and has remained well since returning to work. Would ask to what the cure was due? There had been no history of syphilis, and the treatment had not been anti-syphilitic. He suggested that the erysipelas may have extended down the cord producing congestion, local extra nutrition of the sclerosed lateral column with restoration of function. Diagnosis had been confirmed by several neurologists. —*Med. Record*, Nov. 7, 1891.

ABSCESSES IN THE MEDULLA OBLONGATA.

Eisenlohr (*Deut. med. Woch.*, February 11th, 1892) first refers to the rarity of abscesses in this region as well as in the spinal cord (not of traumatic origin), whereas they are fairly frequent in the brain. The first case occurred in a man aged 43, with fœtid empyema on the left side, and fœtid expectoration. The empyema was incised, a piece of the seventh rib being removed. About three weeks later a second localized abscess in the pleural cavity, communicating with a dilated bronchus, was opened, and a piece of the fifth rib excised. Nine days later there was stiffness and weakness of the left arm, followed by total paralysis of the left side, as well as diminished sensation, and ultimately anæsthesia of the left forearm and hand. The pupils were unequal. Death was due to rapidly increasing dyspnœa. At the necropsy many bronchiectatic cavities were found in the lower lobe of the left lung. On transverse section through the medulla an abscess the size of a pea was found lying between the left olivary body and the floor of the fourth ventricle. The abscess was prolonged downwards as far as the second cervical nerve, and was situated in the posterior columns, but extended also into the gray matter. A smaller focus of round-celled infiltration was found in the right half of the medulla oblongata. The meninges were healthy. The second patient, aged 24, suffered from an attack of cerebro-spinal meningitis. After a varying course of about seven weeks he became restless. The pupils were now markedly unequal, the right being widely dilated and fixed, the left moderately dilated and sluggish. Four days later there was deep stupor and slight left facial paralysis. There were epileptiform convulsions and divergent

strabismus before death. There was no optic neuritis. Whitish gray exudation was found on the under surface of the pons and on the upper and lower surface of the cerebellum. At the level of the corpora quadrigemina and near the aqueduct, the brain substance was destroyed, and some drops of pus found. Round about there were punctiform hæmorrhages and complete softening. The cavity ended opposite the lower corpora quadrigemina. In the first case the abscess was secondary to the purulent change (bronchiectasis) in the lung. In the second case the changes in the pupils were due to the lesion near the anterior corpora quadrigemina. Abscess of the brain in connection with epidemic meningitis has been described, and especially by Strümpell; but Eisenlohr has not found any record of abscess of the cord in this disease.—*Brit. Med. Jour.*

CEREBRO-SPINAL MENINGITIS.

J. S. Nowlin (*Journ of Nerv. and Ment. Dis.*, October, 1891) maintains that the nomenclature of this affection gives rise to an incorrect view of its pathology and treatment. Almost without exception authors have written as though an inflammatory process in the meninges of the brain and cord were the original lesion to be combated. The actual cause of the disease is malarial poison, which primarily affects the nerve centers; any inflammatory action that may be present is merely concomitant or secondary. Quinine is the antidote, and is specially effective if given during the prodromal stage or as a prophylactic. Adjuvants such as calomel, in frequent and large doses, arterial and nerve sedatives, must be freely used. Nowlin furnishes clinical notes of five cases treated by him in one year. Three of the cases died, but no reference is made to any *post-mortem* examination.—*Brit. Med. Jour.*

THE FATTY SECRETIONS OF THE SKIN.

M. Arnozan has imagined (*Annales de Derm. et de Syph.*), a very ingenious method for determining the presence of fatty matters in different parts of the skin. "When small fragments of camphor are thrown into water, they are subject to rapid vibratory movements, which are immediately arrested if the point of a needle which had been rubbed amongst the hair is placed in the water; that is to say, fatty bodies arrest as if by enchantment, the movements of the camphor. If camphor does not turn round in distilled water, it may be inferred that the water contains fatty bodies, or that the walls of the vessel are oily." M. Arnozan quotes this passage from Malagutt's *Dictionary of the Medical Sciences*, and verified experimentally the fact which has been stated, insisting on great care and cleanliness as regards the water and the vessel used. The method has shown him that in a healthy adult, all the skin of the head, the upper part of the trunk—anteriorly and posteriorly—the shoulders and the pubes are covered with an oily layer, the other parts of the the skin appearing to be quite free from it. On the sternum and the shoulders it is present in very small proportions, and on these parts it is sometimes not found. With reference to recent statements which have been made regarding the functions of the sweat glands, he lay stress on the fact that fat is never present in the palms: whilst in the axillæ it was sometimes present and sometimes absent.

NARCOLEPSY IN THE INSANE.

Dr. Szczypiorski reports (*Ann Medico-Psych.*, Nov, and Dec., 1891) the case of an hereditarily degenerate lunatic, with alternate periods of excitement and depression and para-lucid intervals (when persecutory fancies and exaggerated scruples were present), who had several attacks of narcolepsy. These varied from four to thirty-five days in duration. Of the one-hundred and-twenty days he was under care, eighty-seven were consumed in these slumbers.

HICCOUGH AND COMPRESSION OF THE PHRENIC.

A novel method of combating persistent hiccough was recorded by M. Leloir at a recent meeting of the Academy of Sciences (*Lancet*). Some years back he was consulted by the parents of a little patient who was the subject for over a year before of a persistent and distressing hiccough, which recurred every minute or so, and which had resisted every plan of treatment. M. Leloir then conceived the notion of compressing the phrenic, which he

did between the sterno-clavicular attachments of the sterno-mastoid muscle. The compression was digital, and continued for three minutes, causing, however, considerable pain. As a result, the hiccough, disappeared entirely, and has not recurred. Since then he has adopted the plan in several cases of the kind, and always with complete success. The method is simple enough, and can be put in practice by anyone, and is, besides its utility, interesting as an example of the successful application of the researches of Brown-Sequard on inhibition.

HERMAPHRODISM.

The *France Médical*, October 23, 1891, gives a notice of Dr. Charles Debierre's recent work upon this subject, which has been undertaken solely for the following purpose: first, to prove that, from the anatomical point of view, the hermaphrodite is neither a monstrosity nor a freak of nature, but a creature devoid of ordinary development, that is, not developed sexually in conformity with its species. Physiologically, the hermaphrodite is a degenerate, impotent and sterile, imperfect in impulse and characteristic equilibrium, on account of unstable and perverted sex. Socially an unfortunate object, and much to be pitied, the hermaphrodite belongs to the dangerous classes, and society should be warned accordingly. Humanity is either masculine or feminine. The unhappy object of Dr. Debierre's study is neither man nor woman. Before the civil code it would be well to consider the hermaphrodite absolutely neuter, thus excluding the possibility of legal marriages in cases of doubtful sex.

BLACKENING OF THE TEETH BY ANTIPYRINE.

It is asserted that the internal use of antipyrine blackens the teeth; this peculiarity should be generally known by the profession, and also among the laity, that objections may be made on this ground to taking it as a remedy. The blackening is the more intense, the more imperfect the enamel, but may be removed by attrition with dilute acid. The considerable use of antipyrine for several years back, gives importance to this last observation. —*Southern Dental Journal.*

SURGERY.

OPERATION FOR SPASMODIC TORTICOLLIS.

Some advance appears to have been made in the surgical treatment of this most distressing affection; but until its pathology is more clearly ascertained, we cannot hope that the results of treatment will be anything like uniformly successful. One point that lies on the surface is the variations met with in different cases. In one patient the sterno-mastoid muscle may be the only one affected, in another it will not be implicated at all, and similar variations are met with in the case of the other muscles which rotate the head. It is, therefore, difficult in some cases to determine exactly what muscles are implicated and to what nerve treatment must be directed. Difficulty also arises from the depth at which some of the muscles and the nerves supplying them are placed, so that any operation on these nerves involves a very deep dissection. Nerve-stretching, even when very thoroughly carried out, has not been attended with success, and simple division of the nerves has not given better results. Surgeons are now dealing with these cases by the free excision of the nerves supplying the affected muscles, removing the nerves as near to their central ends as possible. Last year M. Petit recorded twenty-six cases in which he excised the spinal accessory nerve. Of these, in thirteen a sucessful result was obtained, seven were much improved, two were slightly better, and three enjoyed temporary benefit only, while one patient died from phlegmonous erysipelas. The operation in question is a comparatively simple measure. The more difficult cases are those in which the posterior muscles are involved. Early last year Dr. W. W. Keen recorded a case in which he had excised muscular branches of the posterior divisions of the first, second, and third cervical nerves with marked benefit, but not complete success. Soon after Dr. Noble Smith recorded a case in which he had performed the same operation on the first, second, third, and fourth cervical nerves. Dr. Powers has now related a third instance of this operation, in which he exactly followed Dr. Keen's procedure. The last two patients were greatly benefited by the operation. Dr. Keen makes a transverse incision

carried down through the complexus. Mr. Smith employed a vertical incision. The results thus obtained are well worthy of the attention of surgeons, although the treatment is only empirical.—*Lancet.*

HYPOGASTRIC NERVE SECTION AND THE BLADDER.

Dr. Lannegrace states (*Prog. Med.*, April 9, 1892) that simultaneous section of the two hypogastric, or lumbar sympathetic nerves, have no effect upon micturition. The bladder retains its responses and tonicity. Trophic changes do not result. Section of the medullary nerves always produces retention which ceases in about three days. The cause of this retention is to be found in a resistance coming on in the neck. The animals may live indefinitely, although motricity and sensibility are evidently diminished, since the animal urinates upon a higher intra-vesicular pressure than can be normally endured. The urine is normal. The bladder has vascular and trophic disorders. The veins are dilated. There are punctate and patch ecchymoses, epithelial erosions, or even superfical ulceration from which hæmaturia results. The submucous tissue is œdematous and infiltrated with round cells. The lymphoid exudation may spread to the muscular layer. The use of sounds, even when aseptic, in animals, causes the urine to become ammoniacal and sanguinolent. The bladder becomes paralyzed and profuse hemorrhages result, frequently causing death. Sub-acute cystitis often results. Section of these nerves, hence, predisposes to contamination. Simultaneous section of the lumbar and sacral nerves results in urinary retention, which lasts from three to six hours, and is due to constriction of the neck and paralysis of the walls. The same trophic lesions result as those just mentioned. One-sided section of lumbar and sacral nerves has no appreciable effect.

THE TREATMENT OF INTRA-MAMMARY ABSCESSES.

Hache (*Rev. de Chir.*, 12e annèe, No. 3) recommends the following as a means to procure the rapid healing of these abscesses:

1. After antiseptic precautions the most important procedure, as in all other abscess cavities, is the procuring of perfect drainage.

2. The compression, uniform and firm, of the gland is the best means to accomplish this end, the position or declivity of the incision being of little importance.

3. To produce this uniform and sufficient pressure concentric compression directly of the gland should be joined to the classic method of pressure against the thorax.

4. Drainage-tubes should be avoided as much as possible, as they render the compression painful and retard the healing.

5. When the abscess is superficial and only covered by a thin layer of tissue, it should be incised in this point. The thinness of the walls renders the use of drainage-tubes unnecessary. He reports four cases in which this method of treatment by compression produced rapid cures with restoration of the secretive function.—*Amer. Jour. Med. Sci.*

STATISTICS OF ELEVEN HUNDRED AND FIFTEEN OPERATIONS ON ADENOID TUMORS

Dr. Menière's (*Revue Therapeutique Medico—Chirurgicale*, December 15, 1891) lecture draws its principal interest from the great experience which he possesses on this subject. He prefers, for diagnosis, digital exploration to posterior rhinoscopy. He insists on the grievous modifications which these growths cause in the skeleton, the facial expression, the hearing, and the general condition of children who have them. The only treatment is removal, and the only instrument advised for this purpose is the cutting forceps. The operation may be done in many sittings, separated by an interval of from five to eight days, removing only one piece at a time, which is done so rapidly that children bear it well as a rule. After each operation the patient gargles with cold water, an antiseptic nasal injection is given, and the ears are closed with cotton. On the day of the operation the patient stays in one room. The average number of sittings is three, and often, at the last one, the pharyngeal wall is scratched with a rigid metallic ring, which procedure clears completely all points not reached with the forceps. Several paintings with pure tincture of iodine complete the cure. The

above method is the one always used by the writer.

The second method is to remove all at one sitting. It is necessary to give an anæsthetic. The flowing of blood is often considerable and a febrile reaction may ensue. The child should keep its bed for some time. Chloroform or any other anæsthetic not being absolutely without danger, it appears useless to employ one in "an operation so mild and exempt from real pain."

A TRAGUS RETRACTOR.

This instrument, recommended by Dr. Cresswell Baber, consists of a ring of flat metal, and the end of the band which forms the ring is bent back obliquely, and forms a blunt hook twelve millimetres in length. Fixed on the tip of the left forefinger in examining the right ear, the auricle is drawn upwards and backwards with the middle finger and thumb, and the tragus is drawn forwards by the hook of the retractor. In examining the left ear the retractor is fixed on the left ring finger. By its help the greater part of the meatus may be examined, and surgical means applied more readily than with ordinary speculum. —*Archives of Otology*, January, 1892.

THE TREATMENT OF MALIGNANT NEOPLASMS.

Krauss, in the *Memphis Journal of Medical Sciences*, for May, 1892, reports the results of a trial of von Mosetig Moorhof's treatment by pyoktanin injections for malignant growths. Two cases were treated; the first case was one of epithelioma, involving the upper half of the left orbit, with the frontal, nasal processes of superior maxillary and anterior portion of ethmoid bones at the inner wall of the orbit. The lower lid was edematous, and on the malar process there was another ulcer, independent of the upper one and involving the bone. Methyl-violet solution 1–4000 was injected, the strength being increased subsequently to 1–250. Fifteen minims to a drachm were injected at a time. The treatment lasted some months, the injections being made every third day. On one occasion a localized cellulitis followed, but had no influence on the progress of the affection. The whole treatment lasted about six months and three months later all traces of the disease were still wanting. The second case was that of an old lady with an irregular lesion two inches long on the forehead. It had existed for thirteen years. After three injections the bulk of the ulcer disappeared. This case was regarded more as lupoid in nature than epitheliomatous. The author concludes his article by saying that we are only justified in treating inoperable cases in this way.—*Univ. Med. Mag.*

OBSTETRICS.

INVESTIGATIONS IN THE HÆMOGLOBIN PERCENTAGE AND THE ESTIMATION OF THE RED BLOOD CORPUSCLES IN THE LAST PERIOD OF PREGNANCY, AND IN THE PUERPERAL STATE

Bernhard (*Münchener medizinische Wochenschrift*, March 22–29, 1892), has compared a series of blood counts of the patients in the Frauenklinik zur Erlangen, with those of healthy, unimpregnated women.

In the examination of twenty healthy non-pregnant working-women, he found an average of 4,458,000 red blood corpuscles and 80.25 per cent. hæmoglobin.

He examined thirty-two pregnant women, from under 20 to over 40 years of age, and from I to VI-paræ. The examinations were made after eight days, one day after delivery, and on leaving the institution, about ten days after labor.

Comparing these results with the average of the twenty non-pregnant women, he found eighteen cases to exceed. Of these in thirteen cases the excess was in both hæmogoblin and red corpuscles, in two cases excess only in hæmoglobin, in three cases excess in red corpuscles. Of the remaining cases the average count was 4,156,000 red corpuscles and 74.6 per cent. hemoglobin. The average of all the investigations made on the entrance of the pregnant women into the hospital was 4,545,000 red corpuscles, and 80.75 per cent. hæmoglobin.

From these he draws the following conclusions:

(1) The average in healthy non-pregnant working-women was found to be 4,458,000 red corpuscles, 80.25 per cent. hæmoglobin. The average in pregnant women 4,494,000 red corspuscles, 80.2 per cent. hæmoglobin.

(2) The percentages of the most important components experienced an increase until the end of pregnancy; in seventeen observed for a long time there was a gain of 2.5 per cent. hemoglobin and 14,000 red corpuscles.

(3) Pregnancy exerts an anemia-producing influence. In strong persons there is, on the contrary, an increase of the blood quality.

(4) With the labor the percentage of hæmoglobin and the blood count fall, principally through the loss of blood in the delivery.

(5) During the puerperal state there is an increase in the quality of the blood. The estimation on the tenth day after labor is equal to that on the day before the labor.—*Univ. Med. Mag.*

GYNECOLOGY.

ACUTE OÖPHORITIS AS A SEQUEL OF INFLUENZA.

In a recent epidemic of influenza Caraglorgiades (*Satellite*) observed a case of acute ovaritis of the left side, which occurred after influenza:—

A married woman, aged 25, neurotic, otherwise healthy, *nullipara*, with regular menstruation and pelvic organs well developed, was, on the 6th of December, 1891, seized with influenza of the nervous type. The attack, which was regular and never gave rise to any anxiety, lasted about ten days, and then convalescence began to be established. It was noted by the patient, with surprise, that her catamenial discharge, four days overdue, had failed to appear. On the next day (a fortnight after the onset of influenza), though the patient was still in bed, she was suddenly seized with rigors, which were followed by fever of a mild form (100° to 102° F.) with slight exacerbation at night. She had, at the same time, nausea, occasional vomiting, loss of appetite, and constipation; pain over the pubes and in the left iliac region on pressure, irritability of the bladder, and tenderness of the vagina. On moving the cervix uteri and passing the finger behind toward the sacro-iliac synchondrosis, severe pain was at once felt by the patient, causing her to suddenly cry out. By combined rectal and vaginal examination the slightly swollen ovary could be easily felt. Pain was produced by the extension of the left leg, and the patient could not lie on the right side on account of the intense suffering.

After a varying course, which lasted over two months, she entered into a period of convalescence. In March, for the first time, she menstruated without any pain or discomfort, and since then the catamenial discharge has appeared regularly. Soon afterward she began to gain strength and complete recovery took place.

The treatment employed was as follows: Absolute rest on the back with the hips raised, dry cupping-glasses applied over the sacrum, leeching twice repeated to the iliac region, turpentine stupes over the abdomen, occasional aperients, and calomel and Dover's powder were frequently used. Bromide of potassium combined with chloral were given, chiefly at night, to combat the insomnia and pain. Diuretics and diaphoretics, associated with hot baths, were of great service. During her entire illness the patient had careful nursing and appropriate diet.

TREATMENT OF THROMBOSIS OF THE VULVA.

Bouilly and Charpentier (*Rev. Génér. de Clin. et de Therap.*, April 20, 1892) recommend the observance of the following rules in the treatment of thrombosis of the vulva: 1. *During pregnancy*: resolvent and cold applications; interference only in case of rupture. 2. *During confinement*: a rapid termination of the labor by means of the forceps or by version; if there is hæmorrhage, the pouch formed is to be opened, removing the clots, followed by the introduction of antiseptic tampons. 3. *After delivery*: expectant treatment; but, if necessary, the thrombus is incised, and the cavity is then washed out and dressed antiseptically.

VAGINAL SECRETIONS.

The May issue of the *Archives of Gynæcology, Obstetrics and Pediatrics* contains a *résumé* of Doederlein's work on vaginal secretions, read by Dr. J. W. Williams, before the Baltimore Gynæcological Society.

Doederlein's object was to find what constituted the normal vaginal secretion, and to determine its relationship to puerperal troubles. Healthy young virgins

were selected to furnish a normal secretion, which is described as a small quantity of whitish, crumbling material of the consistency and appearance of curded milk; it contains no mucus and has an intensely acid reaction to litmus paper. Microscopic examination shows it to consist of vaginal epithelial cells and a large quantity of bacilli. The pathological secretion, on the other hand, is of yellowish or greenish-yellow color and cream-like consistency, and often contains mucus and gas bubbles; its reaction is weakly acid or neutral and sometimes alkaline. The microscope shows epithelial cells, numerous pus cells and a mixture of all kinds of micro-organisms. Among 198 pregnant women examined, 44.6 per cent. had pathological secretions.

A point of decided interest is that the large bacilli were always present in the normal and never present in the pathological secretions. This bacillus produces an acid (probably lactic acid) which causes the normal acidity of the vaginal secretion. The products of the life of this bacillus were proved to be inimical to the growth of most of the pathogenic micro-organisms. Large quantities of pus-producing organisms introduced into the vagina would completely disappear in four days. The bacillus is not pathogenic, and, therefore, sepsis can occur only by having poison germs introduced from without, and even these must be in large quantity to counteract the effect of the acid-producing bacilli of the normal secretion.

The proof of the pathogenic nature of the pathological secretion lay in the effect of injecting this secretion in rabbits—suppuration occurred in each case, and death followed in several. This secretion contains almost all kinds of micro-organisms, and in about ten per cent. of the cases streptococci were found. From these observations it is concluded that as the streptococcus is usually the cause of puerperal fever, and as this organism is found only in about ten per cent. of the cases having a pathological secretion, there is no danger of auto-infection among ninety per cent. of all woman, whether their secretions be normal or pathological; nor is there any justification in these cases for internal disinfection,

Doederlein believes that the streptococci are unable, of themselves, to invade the uterine cavity and produce infection, and holds that the only way for this accident to occur is for the germs to be carried there by manipulation and douching. A practical application of these observations is made in the lying-in-hospitals at Leipzig. Students are not allowed to examine patients until the vaginal secretions have been pronounced normal. Permission is not granted for those cases in which the secretion is pathological. Experiments were made with pathological secretions, during the course of pregnancy, to determine how best to restore the secretions to the normal standard.

Of the many agents used, Doederlein found a one per cent. solution of lactic acid the best. This appeared to produce an unfavorable medium for the growth of the pathogenic organisms, while it supplied the most desirable conditions for the development of the normal vaginal bacilli, which in turn, by their action, made the secretions unfit for harboring most of the pathogenic organisms. In many cases thus treated the pathogenic were sure to give place to the normal vaginal bacilli and the secretions change from an unhealthy to a normal condition.—*Univ. Med. Mag.*

ENDOMETRITIS IN ACUTE GENERAL DISEASES.

Massin (*Archiv für Gynäkologie*, Bd. xl., Heft 1) examined twelve uteri from fatal cases of typhoid fever, pneumonia, etc., and found acute interstitial inflammation of the walls as well as of the endometrium, with superficial hæmorrhages, the latter being most extensive in connection with continued fever. They were apparently due to venous stasis. The glands showed cloudy swelling and granular degeneration of the epithelium, with hæmorrhages into the lumen.

COCAINE IN INTRAUTERINE INJECTIONS.

Lediberder (*Rev. de Chir.*, May 10th, 1892) mitigates and even prevents the pain caused by tincture of iodine when used as an intrauterine injection, by first injecting a 1, 2, or 3 per cent. solution of cocaine. If this solution is kept in contact with the uterine mucous membrane for two or three minutes, the iodine injection causes no pain.

AN UNUSUAL FORM OF SECONDARY CARCINOMA OF THE UTERINE BODY.

Benckiser (*Zeitschrift für Geburtshülfe und Gynäkologie,* Band xxii., Heft 2) found, in a uterus removed *per vaginam* for cancer of the cervix, that the disease had extended above the os internum, the corporeal endometrium being traversed by deep furrows between which were opaque reddish nodules. On microscopial examination the epithelium was seen to be normal in the furrows, while over the nodules the epithelial cells were enlarged and contained large transparent nuclei, while the mucosa was infiltrated with round cells. A few glands still retained their epithelial lining. A small fibrous polypus at the fundus had undergone cancerous degeneration. It was evident that the secondary disease in the corpus uteri had affected only the superficial epithelium, the glands and connective tissue being healthy. The patient being fifty-nine years of age, the absence of glands might be explained as due to climacteric changes. The patient was free from recurrence two years after operation.—*Amer. Jour. Med. Sci.*

CURETTING THE UTERUS BEFORE ABDOMINAL SECTION.

W. R. Pryor (*N. Y. Journ. of Gynæc. and Obset.*, February, 1892) believes that most of the persistent discomfort following abdominal section is due to overlooked and neglected endometritis, and not to adhesions. He is further of opinion that secondary pyosalpinx taking place in tubes which have been left untouched, as apparently healthy, when the opposite appendages were removed, is likewise due to endometritis. The persistent backache, the descent and posterior displacement of the uterus so often observed, are due to the uterus remaining enlarged and heavy from endometritis. All these accidents may be avoided by a curetting preliminary to the major operation. The curette should be most thoroughly applied opposite the tubal openings, because there the endometrium is thickest and hard to reach if inflamed. The vagina should be scrubbed with soap and water and then with a 1 in 3,000 sublimate solution. The iodoform gauze may at once be made by soaking purified mull in the sublimate solution, then rinsing it out and dusting thoroughly with iodoform until the wet gauze can contain no more. Pryor never injects vinegar, iron, iodine, or other astringents into the uterus, and he never uses styptic cotton. By thus destroying the diseased endometrium before proceeding to the grave operation of removing the appendages, the operator will afford the patient the best chance of complete cure.—*Brit. Med. Jour.*

PEDIATRICS.

HERPES ZOSTER IN CHILDREN.

Comty (*Soc. Méd. de Hop. mal. de l' Enf.*, Paris, 1892, x., 31.)finds that in children the eruption is the whole of the disease. In thirty-three cases twenty-one were girls, twelve boys. Among these thirty-three four were less than two years of age, twenty-nine had passed that age. The age of ten was that at which the largest number of cases occurred. The disease showed itself more frequently in the summer months. It was rarely that the children afflicted failed to present something which might predispose them to the disease. Nervous accidents or shocks before the appearance of the herpes were particularly noted. Among the occasional causes a traumatism, which preceded by three weeks a brachial zoster, may be cited. Another time vaccination was followed after eight days by the zoster.

ENLARGEMENT OF THE SPLEEN IN YOUNG CHILDREN AS A DISTINCT DISEASE.

Carr (*Lancet*, April 23 and 30, 1892) in a rather long article treats of a splenic enlargement in children not due to the usual causes of such conditions. He looks upon it as a disease *sui generis*. He bases his views upon thirty cases observed during *three* years—sixteen males and fourteen females. The age varied from two months to two and a-half years. They were usually wasted. There was usually pallor, associated with what the author calls a characteristic splenic appearance, a waxy color with a faint olive tint. The degree of splenic enlargement varied. In all cases it could be felt one inch or more below the margin of the ribs. In half the number the lower edge was on a level with the superior spine of the ilium. The liver was apparently enlarged in half the number. In some cases a few of the

external lymphatic glands were enlarged. In four cases hæmorrhage, occurred, due apparently to the severe anæmia. In two cases there was a faint cloud of albumin. The blood was examined in fifteen cases. The red discs varied from 32 per cent. to 78 per cent. of the normal. The hemoglobin was usually from 50 to 67 per cent. The course of the case is essentially chronic. The prognosis is not necessarily bad, though the disease is of long duration. The most satisfactory treatment is with cod-liver oil and iron.—*Univ. Med. Mag.*

THE ANTISEPTIC TREATMENT OF DIPHTHERIA BY ANTIPYRINE.

This already widely used remedy is likely to occupy a still broader field, according to Dr. A. Vianna (*Comptes-rendus hebdomadaires, Sociètè de Biologie* , 1892, No. 12, p. 109). As a result of laboratory work, finding that a 2½ per cent. solution prevented the development of the diphtheritic bacillus, he concludes that in daily amount of ninety grains, by the mouth or hypodermically to thirty grains daily, with either local applications in powder or as a solution, to an ounce daily, it can be employed with brilliant results.—*Amer. Jour. Med. Sci.*

RADICAL CURE OF CONGENITAL FISTULA OF THE NECK.

Chalot (*Rev. de Chir.*, May 10th, 1892) reports the following case: A lad, aged 17, had a congenital fistula of the neck on the right side, the external orifice being situated 2½ centimetres above the right sterno-clavicular articulation. Purulent fluid escaped from the orifice, and a probe could be passed in for 11 centimetres without reaching the cavity of the pharynx. By injecting a colored fluid into the external orifice the internal opening was discovered just in front of the posterior pillar of the fauces, upon the surface of the tonsil. Chalot operated as follows: (1) The margins of the internal orifice were removed and the opening closed by sutures. (2) The lower part of the fistulous canal was exposed and removed as high as the place where it came into relation with the carotid. (3) The part of the canal near the carotid was thoroughly scraped, so that the walls might adhere together. (4) Closure of the cervical wound, except at one point near the hyoid bone, which was left open to allow drainage. Primary union of the wound followed and a complete cure resulted, the patient being again seen several months afterwards, when no sign of the fistula was visible.—*Brit. Med. Jur.*

ANAL FISSURE AND RECTAL STRICTURE OF CHILDREN.

P. Le Gendre (*Rev. prat. d'obstetriq., de pediatrie—Rev. Inter. de Bibliog. Med.*–April 25, 1892) reports the following two interesting observations: A little girl, 6 months old, after changing wet-nurses several times, was attacked by anal erythema, digestive troubles and pain during defecation. A small sub-cutaneous abscess of the anus was soon formed. The incision of the abscess did not produce any amelioration in the condition of the patient. It was afterwards discovered that she was suffering from a fissure of the anus. Dilatation of this part and cauterization of the fissure with chromic acid, were applied, followed by a cure. The other case was of a little girl also, 13 months old, who began, at the age of 4 months, to suffer from digestive troubles. Constipation was obstinate, notwithstanding the numerous curative measures that were made use of constantly. Afterwards, the child would suffer greatly at the moment of defecation. The mother then noticed that the injections would not go into the rectum. On examination, a fissure was found, and it was impossible to open the sphincter with the finger. The child, being chloroformed, was again examined, and it was then found that the impossibility of penetrating the finger was due, not to a simple spasmodic condition of the sphincter, but to a true stricture. A posterior rectotomy was then practiced by means of the thermo-cautery. The stricture measured 3 or 4 centimetres. The rectal pouch was relieved of the fæcal matters, and an iodoform tent applied. The child fully recovered.

HYGIENE.

INOCULATION OF CHANCROID.

Dr. Coignet formulates the following practical rules: The pricked point should be small and superficial, so as to avoid

as much as possible implication of the deep skin. It should be as far away from the genital region as possible. If by the day after inoculation there is not the least inflammatory areola, you can say at once that nothing will come of it. If there is a slight inflammatory zone, it is impossible to say till perhaps some days have elapsed. If, however, by the day after inoculation there is a well-formed pustule, with greatly inflamed peripheric zone, the result can be put down as positive. In this case it is useless to wait longer and the ulceration should be destroyed at once, before it has a chance to spread.—*Lyon Medical.*

PROGRESS OF CREMATION.

Cremation seems to be making steady progress. The Sanitary Council of Vienna has passed resolutions to the effect that the burning of the bodies of the dead is the safest mode of preventing the evils of earth burial. It has been decided by the Bombay Municipal Corporation to grant the request of an Englishman to be allowed to erect a crematorium for Europeans in the municipal burying ground. The Corporation has granted a plot of ground, measuring 40 feet squre, for that purpose, at a nominal rent of one rupee per annum. The condition attached is to the effect that the crematorium shall be removed at one month's notice if the Corporation so requires.—*Annals Hygiene.*

SOURCES OF SYPHILITIC INFECTION.

Dr. Rassler, in his essay for the M. D. of the University of Kiel, makes a valuable contribution to the literature of syphilitic disease. The *Archiv für Dermatologie und Syphilis* states that Dr. Rassler undertook the labor of analyzing six hundred and thirty cases of syphilis treated in the medical clinic with the object of ascertaining the number arising from extra-genital infection. He found thirty-four such cases, comprising twenty-three of the lips, one of the tongue, two of the mucous membrane of the mouth, and three of the mamma. In three instances the primary sore occurred on the genital organs without connection having taken place, and in the remaining two it was impossible to indicate the locality. The result of these investigations shows that five percent. of all cases of syphilis are due to extra-genital infection. According to other authorities, the proportion varies between one and ten per cent., except in certain parts of Russia, where the proportion is said to reach as high as eighty or ninety per cent."—*Lancet.*

THE BEST NUTRITIVE ENEMA.

Ewald, as a result of experiments, found that eggs, even though not peptonized, were to a considerable extent absorbed by the rectal mucous membrane. According to the *Mercredi Medical* for April 1st, Huber, of Zurich, has recently repeated Ewald's experiments in Prof. Eichorst's clinic, and announces that the absorption of raw eggs is greatly aided by the addition of common salt.

The salt is well borne, and causes, as a rule, no irritation of the bowel. He considers that eggs beaten up with salt, in the proportion of fifteen grains to each egg, are the best for nutritive enema. His method of procedure is as follows: Two or three eggs are taken, and thirty to forty-five grains of salt are added. They are slowly injected by means of a soft rubber tube, carried as high up the bowels as possible. Three such enemata are given daily. An hour before each enema the rectum is cleaned out by means of a large injection of warm water.—*N. Y. Med. Times.*

MEDICAL CHEMISTRY.

THE SALIVA IN DISEASE.

Jawein (*Wiener Medizin. Presse,* 1892, Nos. 15 and 16) has made a study of the saliva in various conditions of disease. He found that the quantity is increased in slight febrile affections, while the fermentative activity remains unchanged, the absolute amount of ferment produced being diminished. In severe febrile affections, the quantity of saliva is considerably diminished, but the amylolytic activity is increased. The diminution in quantity is greater than the increase in activity, so that there is an absolute diminution in activity. In more severe febrile affections, a minimum quantity is secreted, the amylolytic activity being likewise diminished,

the reduction in both being in direct ratio to the severity of the disease. After a crisis, the quantity and fermentative activity of the saliva falls below normal. In acute febrile diseases of protracted duration, the quantity is not rarely normal, the amylolytic activity, however, being subnormal. In even severe cases of pulmonary tuberculosis, neither the quantity of saliva nor its fermentative activity is diminished. A few days before death, the quantity undergoes change, the activity remaining unaltered. In chronic nephritis, the quantity of saliva is diminished, and its amylolytic activity is not rarely below normal, with attendant diminution in production of ferment. In ascites, the production of ferment is greatly diminished; especially is the quantity of saliva diminished; while the fermentative activity undergoes but little change. In protracted, debilitating affections, such as scorbutus, diabetes, Addison's disease, the production of the salivary ferment is not uncommonly diminished.—*News.*

ON THE ESTIMATION OF MILK SUGAR IN MILK.

In determining sugar of milk in the usual manner by Fehling's solution, the difficulty is encountered that the filtrate (from the coagulated milk) is usually too opaque for titration. A. H. Gill recommends (*Journ. anal. Chem.*, 1891, 652) to mix 25 Cc. of the milk with 15 Cc. of milk of alumina and 0.5 Cc. of 25 per cent. acetic acid, to stir, then to heat five to seven minutes over a water bath at 85° C., to add 100 Cc. of water, and to heat again during ten minutes in boiling water under constant stirring. The liquid is then allowed to become cold and to deposit, and the clear portion decanted through a filter into a 500 Cc. flask, the precipitate being prevented as much as possible from getting on to the filter. The operation of boiling and filtering is repeated three times, and the filtrate finally made up to 500 Cc. It is now in condition to be titrated with Fehling's solution. The "milk of alumina" is obtained by precipitating 125 Cc. of ammonia alum with ammonia at a boiling heat, washing the precipitate by decantation, and finally adding water to make the mixture of precipitate and liquid measure 1,000 Cc.

NEWS AND MISCELLANY.

AMERICAN DERMATOLOGICAL ASSOCIATION.

The sixteenth annual meeting will be held at the Pequot House, New London, Conn., September 13th, 14th and 15th, 1892. Secretary and Treasurer, G. T. Jackson, M. D., of New York.

PROF. DA COSTA DISCONTINUES TEACHING AT THE JEFFERSON MEDICAL COLLEGE.

The profession will learn with great regret that Dr. Da Costa has announced that he has decided to discontinue all teaching in connection with the Jefferson Medical College. Dr. Da Costa has for many years been one of the most brilliant teachers in that institution, and his loss must be keenly felt.

RUSH MEDICAL COLLEGE APPOINTMENTS.

Dr. Chas. Warrington Earle, formerly connected with the College of Physicians and Surgeons, has been called to the chair of Obstetrics and Diseases of Children in Rush Medical College, recently made vacant by the death of the late Prof. Knox. Dr. A. C. Cotton, who has for many years been connected with Rush Medical College as an Adjunct Professor, has been elected Clinical Prof. of Diseases of Children.

PUNISHING ADULTERATORS.

How they treated those convicted of this crime in olden times. The *Muenchener Neueste Nachrichten* says: Our jolly adulterators of food and drink have cause to congratulate themselves that the "good old times" are past, and that their little jokes in this line are no longer looked upon in so tragic a fashion as whilom in the good town of Nuremberg. In the "Annals of the City of Nuremberg" of Counsellor Balthasar Muellner, which are kept in the archives of the ancient burgh, among other very interesting documents there are certain notices of the laws for the punishment of adulterators of food, whose Draconic terrors far overstep, in bloodthirsty penalties, the sanguinary code of Kaiser Karl V. In the year 1456,

Hans, Koelbel, a citizen of Nuremburg, and Lienhard Frey, of Thalmessing, for having adulterated some saffron, were, along with their adulterated wares, "on Friday after Misericordias," burned alive at the stake, and a woman who had assisted them was buried alive on the Monday after Boniface. In Anno. 1459, Ulrich Heydenheimer, citizen of Nuremberg, having added water to the wine which he was selling, was, by special act of grace, let off with the light punishment of losing both his ears. In Anno. 1464, Margareth Wessnerin, a huckster, who was caught in giving light weight, was buried alive near the common gallows. Such punishment had at that time, perhaps, no more effect in deterring adulterations than our laws of to-day.

SO-CALLED "HYDRARGYRUM LACTATUM"

A casualty from the misuse of drugs is reported from Bay City, Michigan. Somebody blundered, and somebody else lost his life; so says the *Western Druggist.* A physician of that town fell into the habit of prescribing "hydrargyrum lactatum," meaning thereby a preparation furnished by a Chicago dealer in drugs, which is said to contain one part each of calomel and of bismuth subnitrate, and eight parts of milk sugar. This did no harm so long as the prescriptions were taken to the shops where the Chicago specialty was known. But the day came when a change in pharmacists was made by the patient. The new pharmacist ordered through his wholesale dealers a bottle of "hydrargyrum lactatum," and received a supply of Merck's "lactate of mercury." Merck's catalogue contains that item, with the price marked at $1.00 an ounce. Chemistry recognizes "hydrargyri lactas," or mercurous lactate, and although it is not often heard of in medicine, Watt's *Dictionary of Chemistry* describes its composition and properties. This preparation was dispensed three times before any injurious effects were noticed, but the fourth dispensing of it was followed by the death of the patient. An analysis of the drug is said to have shown the presence of mercuric lactate as well as of the mercurous salt, and it is suggested that a reduction had been going on in the bottle after it left the wholesaler's hands. If this is the fact, and can be proved, it will tend to lighten the condemnation launched by the *Western Druggist* against the conductors of the Chicago drug-house for its "criminally reckless terminology," in that they adopted a harmful name to cover a comparatively mild "specialty." It will also tend to lighten the feeling of responsibility for this peculiar "accident" in the mind of the physician, against whom the *Druggist* alleges that his conduct was "little less then criminal," because he prescribed a substance about which he really knew nothing. There seems to be a fatality about nearly all these "specialities or combinations made by some known-to-us-alone process;" sooner or later, they become the occasion of loss of life, or they get everybody into trouble who has anything to do with them. The remedy of known composition is not always safe, but it comports more thoroughly with the dignity of the profession to employ it, so that even if perchance a casualty should follow its legitimate use, it would not be necessary to resort to that most idiotic of excuses, "I did not know it was loaded"—the plea of those who point pistols at their best friends and kill them!—*New York Medical Journal.*

ASSOCIATION OF HOSPITAL PHYSICIANS AND SURGEONS OF PHILADELPHIA.

The Association of Hospital Physicians and Surgeons of Philadelphia was organized to afford physicians who visit the city, and desire during their stay to take advantage of the clinical facilities of the various hospitals, an opportunity to witness practical work in any line of general or special medicine or surgery in which they may be interested.

A roster can be had by application to Dr. H. R. Wharton, 112 So. 18th St., Phila.

Pharmaceutical Products of the Farbenfabriken vorm Friedr Bayer & Co

Sulfonal-Bayer

induces sleep, free from narcosis, and sequelæ. It acts purely as a hypnotic and claims no analgic powers. Sulfonal is also of the highest value in the neuroses and is largely employed by neurologists. It is a safe remedy and its continuous use does not give rise to a drug habit. Sulfonal must be given according to directions. (*Supplied in ounces.*)

Salophen

is a new salicylo-phenolic derivative said to be so combined, chemically, as to constitute a safer and more effective remedy than either of its components, or any analagous preparation. The reports refer in the highest terms to its value in rheumatism and allied affections. Competent observers recommend it for extended trial. (*Supplied in ounces.*)

Europhen

is a complete substitute for iodoform and is a cicatrisant of special value in specific lesions, catarrhal and ulcerative diseases and all surgical conditions formerly treated by the latter preparation. It has five times the covering power of iodoform and forms an impervious coating over denuded tissues. Europhen has a faint, agreeable odor resembling that of saffron. (*Supplied in ounces.*)

Phenacetine-Bayer

continues to justify the high praise of physicians, and it may properly be considered as the best of the modern antipyretics and anodynes. In *la grippe,* rheumatism, migraine, neuralgia, etc., it is a prompt, safe and effective remedy. Phenacetine, unlike the secret mixtures announced as analgesics and antipyretics, is a true organic derivative. (*Supplied in ounces.*)

Aristol

is now widely used as an agreeable and effective dressing in all of the operations of major and minor surgery and in dentistry. It is invaluable in ulcerations of all kinds, and in burns, blisters and bed-sores. It adheres closely to mucous membranes and wound surfaces. (Aristol and "Europhen-Aristol," a combination of both remedies are supplied in ounces.)

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{60}$ gr.), Atropiæ Sulph. ($\frac{1}{100}$ gr.), Codeia ($\frac{1}{30}$ gr.), Antimony Tart. ($\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{30}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonial from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of th profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that th applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double, boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

26 Maiden Lane, **New York City.**

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL & NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

Clinical Lectures.

SURGERY OF THE GALL-PASSAGES AND LIVER.

By. DR. W. KÖRTE,
BERLIN, GERMANY.

Continued from the last issue of The Reporter.

ABSCESS OF THE LIVER.

Circumscribed suppurations of the liver are much more rarely observed in our climate than in the tropics.

With us they are most frequently caused by gall-stones and suppurations of the appendix. Metastatic pyæmic abscesses of the liver are of course not included in this category.

Thrice I have seen extensive suppurations of the liver resulting from gall-stone, while small foci of suppuration, following the gall passages in the liver, I observed in two other cases (Cases X and XIII). This last affection cannot be treated surgically, for while the larger abscesses may be opened and will heal up, if they can be found of course; this cannot be done with the smaller multiple abscesses. In the Case XI, the history of which has been given in another part of this article, the gall-stones had set up a suppuration between the gall-bladder and diaphragm, as well as in the left lobe of the liver, next to the gall-bladder. The opening of this latter abscess was undertaken from the same superficial incision used in laying bare the gall-bladder, and by means of drainage and the iodoform gauze tampon, was encouraged to heal. The second case of abscess of the liver occurred in the case of a woman (Case XV) whom I had treated for continued gall-stone colic. In this instance I sought in vain by means of repeated punctures to locate the point or points of suppuration. The autopsy revealed a large abscess in the left lobe of the liver, a similar one in the right lobe, and besides these several smaller abscesses. It is doubtful, therefore, whether a complete evacuation of the pus could have been effected in this case by any means.

In a case observed by Dr. A. Fränkel* in the Internal Department of the hospital, the possibilities offered for recovery were far more favorable. In this case, during the life of the patient, active measures were taken to locate the seat of suppuration, but in vain. The autopsy revealed one large abscess in the right lobe of the liver, which had it been found might easily have been opened and evacuated. The pus in this abscess contained a pure culture of the *bacteria coli commune*.

Abscesses of the liver may also occur after perityphlitic suppurations, either through pyæmic infection, when it has not been possible to locate or open the primary point of suppuration†—or a direct migration or continuation of the suppurative process in the retrocæcal connective tissue, up to that portion of the margin of the liver not covered by the peritoneum. In such cases the pus usually enters the subphrenic space, but occasionally penetrates directly into the liver where it sets up a circumscribed point of suppuration. Such a peculiar and rare course, I was able to trace in Case XIV. Here Dr. A. Fränkel was able to find the suspected abscess in the upper portion of the right lobe of the liver, by means of the exploring needle. After resection of a piece of the eighth rib, six or seven centimetres long, I opened into the pleural cavity and from there by puncture through the diaphragm again succeeding in finding the abscess, which I then cut into through

*See *Deutsche med. Wochenschrift*, No. 48, 1891.

†See my article on Perityphlitis in the *Berliner klin. Wochenschrift*, No. 27, 1891.

perhaps an inch of liver tissue. The hæmorrhage was quite extensive but was finally checked by compresses, and about half a pint (¼ litre) of fœtid pus was evacuated. The abscess cavity was large with irregular walls. In the pus evacuated, besides a number of other micro-organisms, the *bacteria coli commune* was found. At first I was far from entertaining any very sanguine prognosis, since I suspected the existence of other abscesses of the liver. The fear proved, most fortunately, to be unfounded, for within three months the abscess cavity had entirely healed up.

The symptoms which led to the diagnosis of abscess of the liver were as follows: High remitting fever, with chills, icterus, dry tongue, general symptoms of sepsis, and accompanying these a dull pain in the region of the liver, which was greatly increased by pressure over the affected parts. The proof was offered by the exploring needle, but frequently many punctures were necessary. In one case at the request of Dr. A. Fränkel, in a patient who had every symptom of abscess of the liver, which, however, had not been found by the exploring needle, I laid bare the liver and endeavored to find the abscess by palpation, but in vain.* At the autopsy, which was performed ten days later, I found a perityphlitic abscess deep in the small pelvis, with pylephebitis and enlargement of the liver without abscess. Both *intra vitam*, as well as *post mortem*, it could be seen that the punctures were well borne by the liver and gave rise to no reaction. Indeed the places where the needle had been introduced could not be found at all.

The *bacteria coli commune* seems to be the most frequent participator in abscess of the liver. We found it in two cases, and also once in the gall-bladder.

The treatment of abscess of the liver, from the most rational point of view, consists in incision performed at one sitting. The point of incision varies, naturally, with the location of the abscess. If one can reach the abscess from the abdominal cavity, an incision here should be preferred. Only then when the abscess is situated very high, at or near the apex of the liver should the opening be made through the pleural cavity. Puncture of liver abscesses has also been successfully performed with a thick trocar by Israel and others. In very feeble and weak subjects this method seems recommendable, since it considerably simplifies the operative procedure.

*See Dr. A. Fränkel's article in the *Deutsche Med. Wochenschrift*, 1891, No. 4.

Perityphlitis; hepatitis suppurativa; incision after resection of the eighth rib, through the pleural cavity; drainage; metastatic abscess under the gluteal muscle; recovery.

Case XIV. H. N., thirty-nine years old; driver. The patient had frequently suffered from perityphlitis, the last time during the May of 1891. After a relapse a continued septic fever followed. Pain in the region of the liver. Puncture with the exploring needle revealed deep pus in the liver.

On June 10, 1891, the patient was transferred to the surgical department of the hospital. An incision was made over the eighth rib, back of the line with the axilla, eight centimetres of the eighth rib were incised; the pleural cavity opened and immediately closed with iodoform gauze. The diaphragm bulged forward and was incised, and through the incision the smooth surface of the liver seen, and after a single exploratory puncture, and incision made two centimetres into the substance of the liver, and a large cavernous abscess cavity evacuated, and syringed out with lysol and sterilized water. Iodoform tampon and a drain was then inserted.

The patient was greatly collapsed and powerful excitants were administered. For about four weeks a high evening temperature continued. From the pleura there were no untoward symptoms. Subsequently a large metastatic abscess formed under the right gluteal muscle, which had to be opened. There was no secretion of gall. The deep wound in the liver healed gradually by granulation.

The patient was discharged on September 11, 1891, as completely cured.

He again reported on November 16, 1891 in excellent health.

Cholelithiasis; abscess of the liver; death.

Case XV. J., thirty-six years old, seamstress. The patient led a sedentary life and laced. She aborted once; in 1882 she had inflammation of the appendix.

In July, 1886, she had icterus with painful enlargement of the liver, but no colics. During September of 1886 she had a relapse. On November, 24, 1886, gall-stone colic appeared, and a similar attack occurred on Dec. 27, of the same year. During June, 1887, she had gastric catarrh and icterus. She then underwent the Karlsbad cure. On July 23, 1887, she had a severe chill followed by high fever, and great depressian. From that time a high remitting fever continued, with severe icterus. Fæces colored, dull pain in the region of the liver. The liver was enlarged. The chills returned, but no gall-stone colic.

The presence of an abscess of the liver was suspected, and repeated exploratory punctures made, but without result.

On August 20, 1887, death occurred under symptoms of increasing weakness.

The autopsy was made on the evening of the same day.

The liver was found enlarged, especially the upper portion. Its peritoneal covering was covered with fibrin and adherent to the diaphragm.

In the left lobe of the liver, close over the ensiform process of the sternum was found a large abscess reaching up to under the apex of the liver. A similar abscess was found in the apex of the right lobe, and besides these, numerous smaller abscesses were found in the course of the gall-passages in the liver. The gall-bladder was covered with adhesions, contracted and contained light yellow gall, and three cholestearin calculi. The mucous membrane of the gall-bladder was not ulcerated. The cystic and choledochus ducts were not occluded. The blood-vessels of the liver in the *porta hepatica* were free. Nothing abnormal was found about the bowels.

SUBPHRENIC ABSCESS.

Suppuration between the liver and diaphragm—subphrenic abscess—was found in five cases as resulting from perityphlitis;* once in consequence of gall-stone (Case XI), and once in consequence of an old pyelonephritis.

The diagnosis was made as follows: First, from the knowledge of a previous inflammatory disease of the abdominal cavity; second, from the existence of a remitting fever, which would point conclusively to the existence of suppuration; third, from the fixed pain in the intercostal spaces, over the liver; fourth, from the results of percussion which demonstrated the enlargement of the liver while the pleural cavity was found empty, or else containing a serous exudate; and fifth, the examination by exploratory punctures which resulted in confirming the diagnosis beyond doubt. Punctures were frequently made through the healthy pleura, without occasioning any harmful results. The muscular fibres of the diaphragm quickly closed up the puncture. In one patient the following characteristic condition was found by percussion to the right, at the back above the *spina scapulæ*, there were the usual lung resonance, but below this dullness (serous pleural exudate); then from the eighth rib downward tympanic resonance (subphrenic abscess containing gas), and below this again, the liver dullness.

For the opening of these abscesses two ways are open to the operator. Either transverse incision is made at the back, below the twelfth rib, and from there following the diaphragm the abscess opened into; or else a rib (usually the eighth) excised in a line with the axilla and from this opening through the pleural cavity, the upper apex of the diaphragm incised. As to which is the most preferable method of procedure, can only be determined by the location of the abscess. I have in four cases cut down upon the abscess from the back and below, and three times from above through the pleural cavity. The pleural walls were adherent in two cases, and in one case the free pleura was opened, and then shut off by a tampon of iodoform gauze. The pleura reacted by discharging a moderate serous exudate. Of the severe cases of subphrenic abscess operated upon, six recovered, while one patient (a woman) died. The patient had suffered for years from an open fistula in the right kidney region, and also from chronic nephritis. The opening was made from this fistula by a transverse incision under the twelfth rib, and into an abscess which extended to the apex of the diaphragm. The abscess cavity gradually healed up, but the fistula remained open, the urine contained cylindrical crystals. An attack of erysipelas starting from the

* *loc. cit.*

*See XI *loc cit.*, and cases 2, 9, 10, 11, 13, *Berliner Klin. Wochenscrift*, No. 27, 1891.

fistula, and in connection with the nephritis caused death.

The autopsy showed that the right kidney had been transformed into a mass of dense cicatrical tissue filled with small single abscess cavities, and that not a trace of the kidney substance was discernible. The subphrenic abscess had healed up. The left kidney was in a condition of chronic inflammation.

ECHINOCOCCI OF THE LIVER.

Three cases of echinococcus of the liver have come under my observation (Cases XVI to XVIII). All the patients admitted to having dogs about them, and coming constantly in contact with them. The treatment always consists in laying bare, stitching fast, and opening of the sack, at one sitting. The cysts may be absolutely shut off from the abdominal cavity, by a circular row of sutures, lying close to each other and carefully made with fine round needles. The line of sutures is then protected as in the case with the gall-bladder with a coating of collodion, and over this a wick saturated in iodoform vaseline, then the sack opened. This precautionary method was always found efficient. In one case (XVIII) the sac when operated upon was found to be suppurating. This case shows the great danger of punctures though the skin in abdominal echinococci. The exploratory puncture had only been made the day prior to the operation and yet when the abdominal cavity was opened, a large amount of a turbid fluid, containing numberless streptococci, was discharged, and from one of the punctures in the sac the putrid contents was being discharged. The sac was closely sewed into the abdominal wound and then opened and evacuated. The dreaded peritonitis did not supervene; but unfortunately this patient whose peritoneal cavity had thus withstood the inroads of the most dangerous pus-coccus, died four weeks after the operation from inflammation of the gall-passages.

The secretion of gall was in all three cases very profuse, and here, as in the cases of gall-bladder fistulæ previously referred to, I was forced to the conclusion that this great loss of gall greatly weakened the patients. The quantity secreted in Case XVIII varied from 400 to 500 grammes daily, and in case XVI was even as high as from 600 to 1100 grammes a day. This patient in spite of an otherwise good condition fell away greatly during the loss of the gallic fluid.

Syringing or washing out of the sac was not done immediately after the operation except in the case where suppuration exists. The discharged gall was odorless and not decomposed. The freshly discharged gall was of a golden-yellow color, while that which had been exposed to the air, assumed a greenish hue. Therapeutic measures adopted to check the immense secretion of gall proved futile. The following were used: injections into the sac of slightly astringent solutions, such as a five per mille solution of chloride of zinc, and a one to four per mille solution of nitrate of silver, etc.; besides these, packing of the cavity with gauze, plugging of the fistula (Israel), but all without any results. This copious discharge of gall, in an otherwise aseptic case, constituted a danger not to be underestimated. In one case, (XVIII) I illuminated the cavity with the cystoscope, but was unable to find the source of the gallic secretion.

Echinococcus of the liver; operation at one sitting; copious discharge of gall; pleuritis (tuberculous ?) during the course of healing; discharged with fistula; recovery.

Case XVI. A., twenty-three years old; laborer. Had frequently played with and petted dogs. In 1888 he first noticed a pain and swelling of the liver. During May of 1891 he was suddenly taken ill with severe pain in the region of the liver.

He was admitted on May 5, 1891 to the Internal Department of the hospital. The typical distension of the liver was present, and a semispherical, tense enlargement bulging forward to the right and close to the median line.

On May 20, 1891 the patient was operated at one sitting. The sac sewed into the abdominal wound, then incised, and a large number of echinococci evacuated. The sac in the liver had an opening about three centimetres long in its base, which led into another sac, this also contained large quantities of echinococcci. The sacs were washed out with lysol and sterilized water, and a drain inserted,

A most copious secretion of gall followed, 600 to 1190 grammes in twenty-four hours.

In June the cavities were washed out

with a 5 per mille chloride of zinc solution, and with Lugol's iodine solution and others.

In July the secretion became less. The patient recovered strength rapidly and was able to walk about.

On August 6, the fistula only discharged slightly, and the general condition of the patient was good.

On August 26, the patient caught cold and sickened with a left serous pleuritis, accompanied with high fever. The secretion of gall became more copious. This illness lasted until September, and then the temperature gradually fell, and suspicious symptoms pointing to the presence of tuberculosis were present (catarrh at the end of the lung.

The patient was discharged by his own request, with the fistula still open, on October 5.

During the early part of the following January, he reported in excellent health.

Echinococcus permagnus hepatis; operation at one sitting; recovery.

Case XVII. G., engraver, twenty-six years old. In his youth he had suffered from an inflammation of the hip-joint, and still retained a suppurating fistula at the hip. A year and a quarter ago the physician first noticed that his liver was enlarged. For three months back the swelling had rapidly increased in size, and caused the patient many difficulties. Two years previously the patient had owned a dog that had been with him constantly. The patient looks pale and limps on account of an ankylosis of the left hip. The entire right side of the abdomen is enormously enlarged by a fluctuating tumor, reaching from the edge of the ribs to the *spina ilei*, and from the axillary line to a hands-breadth beyond the median line. On percussion the enlargement had a dull sound, and in several places the growth felt like a hydatid. The upper border of the liver dullness was at the fourth rib. Heart and lungs are sound. Urine moderately albuminous but containing no cylinders. Slight œdema of the scrotum and dorsal surface of the feet.

On October 17, 1891, the single operation was performed.

A transverse incision was made at the margin of the ribs, eleven centimetres long. The cyst then sewed to the abdominal wound and opened. A large quantity of yellow fluid was evacuated, as well a large "Mother" echinococcus egg and several smaller ones. The cavity was then washed out with sterilized water.

The course of the healing was without any reaction. A passing but severe discharge of gall occurred which affected the patient profoundly. The wound is now entirely healed, save for a small fistula.

At the end of December, 1891, the patient was discharged cured

---

Extensive echinococcus of the liver; single operation; improvement; death four weeks later from suppuration of the gall-passages; peritonitis healed.

Case XVIII. S., woman thirty-two years old. The patient fell ill during the latter part of December, 1890, with pains in the region of the liver, chills and icterus. During the early part of February, the abdomen became enlarged. The patient had had a dog to which she was much attached, and which she had carefully cared for.

She was admitted to the hospital on February 16, 1891. The patient then had severe icterus, and a high fever. The liver enlarged to the navel, and fluctuated at this point. Exploratory puncture on February 17, revealed pus with bacteria.

On February 18, 1891, laparotomy was performed. The liver was found covered with fibrin, and from the abdominal cavity a turbid, serous fluid, the color of gall, was discharged in which numerous streptococci were found by the microscope. From the opening in the sac made by the exploring needle, there exuded a putrid fluid. The sac was then stitched fast to the abdominal wound. The incision allowed the evacuation of three litres (quarts) of a putrid gallic fluid, a broken-down "mother" echinococcus and countless smaller ones. The cavity was washed out with a salicylic boric solution, and strips of iodoform gauze inserted. The dreaded peritonitis, rendered so imminent by the introduction of streptococci into the abdominal cavity, did not occur. At first the patient began to recover, in spite of a slight rise of temperature in the evening. The discharge of gall was most profuse amounting to 400 or even 500 grammes a day. The icterus did not entirely disappear. On March 12, a chill occured, and the fever increased. The patient died on March 18.

Autopsy: On the serosa of the abdominal cavity there were only thin, mucus-like threads of adhesions, but no fresh peritonitis. The echinococcus cavity in the right lobe of the liver was greatly shrunken. It was found to communicate with the gall-passages. In the liver multiple abscesses following the courses of the gall-passages were found.

TRAUMATISMS OF THE LIVER.

Only two cases of gun-shot wound of the liver have come to my notice. The one patient (Case XXI) had been shot through the *flex. coli sinistra*, stomach, and right lobe of the liver, and was brought in for treatment sixteen hours after the shooting. The opening of the abdominal cavity revealed the presence of a most intense, diffuse peritonitis which precluded all possibility of a recovery. The injury to the liver itself had not been attended by any hæmorrhage of moment. Indeed, it sank into insignificance in the face of the severe injuries to the intestinal canal, and received no treatment whatever.

In the second case, the bullet had passed through the left lobe of the liver, and had buried itself in the gastro-hepatic ligament. The symptoms of internal hæmorrhage—increasing paleness, small rapid pulse, vomiting, and pain in the abdomen—pointed to the necessity of an immediate operation. From the point of the bullet's entrance into the liver, there was a moderate hœmorrhage. This was easily controlled. On the other hand, there was a very serious hæmorrhage from the upper surface, and from the gastro-hepatic ligament. As it was impossible to sufficiently lay bare the points of hæmorrhage, a form of iodoform gauze tampon was used with good results.

Hæmorrhage constitutes a great danger in all wounds of the liver. In all operative injuries to the liver a profuse hæmorrhage is usually seen—"it bleeds as though from a cavernous angioma," says Burckhardt. Usually, however, compression continued for a time suffices to check the hæmorrhage, similarly as in the case with kidneys. In iodoform gauze we possess a material admirably effective as a tampon, and strips of the gauze may be left in place without doing any harm whatever, and the surrounding parts still being kept aseptic. The strips of gauze, if allowed to protrude from the wound, act as drains as well, and materially assist in the formation of rapid adhesions and quick healing in the abdominal cavity. For those hæmorrhages of the liver that cannot be checked by transfixion, closing by suture, or by the cautery, the iodoform gauze tampon is the final resort. Burckhardt has not failed to call attention to this fact, in his articles on this subject.

In a third case of shot-wound of the epigastrium, I opened the abdominal cavity on account of symptoms of internal hæmorrhage. The bullet, however, had penetrated between the liver and diaphragm without occasioning any great hæmorrhage. In this case laparotomy was really unnecessary, since the symptoms which pointed towards internal hæmorrhage, were undoubtedly due to shock alone. The abdominal wound healed uneventfully. All the same I would in future, in similar cases, proceed as actively as in the above, if there was any suspicion of internal hæmorrhage. The opening of the abdominal cavity—especially in hospitals where every aseptic precaution can be rigidly adhered to—is an operation which can be confidently undertaken, without jeopardizing the patient's life, while an unchecked hæmorrhage into the abdominal cavity will occasion the most threatening dangers.

Once, in a case of crush of the lower part of the thorax, where on the second day peritonitis set in, laparotomy was performed. The diagnosis of traumatic peritonitis had already been made, and it was known that some abdominal organ must have been crushed. The presence of blood in the urine, naturally led me to think of rupture of the bladder, although the urine was voided naturally. It was not until the abdomen had been opened and the gallic consistency of the exudate recognized, and fragments of the liver substance found between the loops of the intestines that the real nature of the injury was determined upon. This was confirmed further at the autopsy.

Such cases reach to limits of our surgical possibilities. Should this case have been diagnosed early enough, and had the injury not been too extensive—in the case mentioned it was not a complete crush, but a T- shaped laceration—then it might well be imagined that an opening of the abdomen with the application of the iodoform gauze tampon, might not only check the

**Centralblatt für Chirurgie*, No. 5. 1887.

hæmorrhage but, prevent the spread of inflammation.

As in every branch of surgery, so also of the liver, the greatest points of importance are the determination of the exact diagnosis, and the indications for operation. The technique and execution of the planned operation are matters of secondary consideration.

Gun-shot wound through the liver, diaphragm; laparotomy; recovery.

Case XIX. S., twenty-five years old. August 4, 1890, the patient shot himself with a revolver in the abdomen, close under the ensiform process of the sternum. The pain was moderate. Pulse small and quick; no vomiting. The patient's face was pale, and his extremities cool. On account of the symptoms of internal hæmorrhage, laparotomy was performed on the evening of the same day (August 4th), the abdomen being opened from the ensiform process 10 centimetres downward. The bullet was found to have penetrated between the liver and the diaphragm; there was no hæmorrhage. The abdominal wound was closed without the bullet having been found.

The patient made a good recovery.

Gunshot wound in the left lobe of the liver and omentum minus; laparotomy; recovery.

Case XX. G., thirty-one years old. The patient shot himself two hours before admission, on October 22, 1892. He complained of severe pain, and vomited, but no blood; the upper part of the abdomen painful on pressure. Pulse small and rapid. Close under the ensiform process of the sternum was a small bullet hole with a black margin. On account of another operation being in progress at the time the patient was forced to wait two hours longer. The vomiting continued but contained no blood, and owing to increased symptoms of collapse laparotomy was performed, by 10 centimetres long, downward from the ensiform process. The liver being exposed a round opening with torn, and irregular borders, was seen in the left lobe of the organ. There was considerable hæmorrhage, which two transfixion stutures sufficed to check. Under the liver there was a larger hæmorrhage, and after lifting the edge of the liver up everal large clots came away, and under this fresh blood made its appearance. The stomach was drawn forward and a slight injury was found on it, but aside from this a large amount of blood flowed from the gastro-hepatic ligament. Two transfixion sutures were inserted but this only checked the hæmorrhage in a measure. A firm iodoform gauze tampon was then inserted, and an end of the gauze strip allowed to protrude from the abdominal wound, at its upper angle. The rest of the wound was then closed. A firm compress bandage was then applied and a sand-bag laid on the abdomen. A subcutaneous injection of camphor was given, as well as opium per rectum.

On October 23, the day after the operation, the patient was still vomiting a great deal, and the pulse rapid. The dressings were soaked with blood, and the compress therefore changed.

On October, the vomiting ceased, and the abdomen became soft, gases were passed per anus.

On October 26, the iodoform gauze was removed without causing any bleeding. A small drain was inserted. The general condition of the patient was good.

On October 30, the drainage tube was shortened, and the wound was closing.

On November 12, the wound was entirely and firmly healed.

On November 16, 1891, the patient discharged as perfectly cured.

Gunshot wound of the colon, stomach and liver; peritonitis; laparotomy; death from collapse.

Case XXI. D., thirty-four years old. The patient was a strongly built laboring man, who was shot with a revolver at a distance of about twenty paces. The shot entered the left side of the abdomen. and immediately caused profound symptoms of collapse. The shooting occured between ten and eleven o'clock in the evening. The bullet was cut out by the physician from close under the arch of the rib. The patient was then brought to the hospital in a wagon, the journey lasting six hours, starting the next morning

The patient arrived at the hospital about noon, July 24, 1891. He was greatly collapsed, had cold extremities, and a scarcely perceptible pulse. The abdomen was very painful but not distended. Below the left border of the ribs, in the axillary line, was the shot-wound. and under

the border of the right ribs, between the axillary and mammillary line was the incised wound through which the bullet had been removed. Out of the latter, a serous, turbid fluid was discharged. The patient vomited frequently. Hypodermic injections of camphor were given, and the patient anæsthetized with ether. The abdominal incision made, reached from the ensiform process to the navel. The abdominal cavity contained a putrid, serous fluid, smelling of the contents of the stomach, the intestinal loops were covered with a layer of pus. In the stomach near the great curvature there was a torn wound three centimetres long, which was sewed up. In the decending colon there were two wounds, from which fæces exuded; these were also sewed up. The right lobe of the liver was also shot through. There was but little blood in the abdominal cavity. Death occured from collapse at half-past two on the afternoon of the same day.

The case being one for the coroner, a judicial autopsy was performed.

Fracture of the fifth, sixth, and seventh ribs of the right side; rupture of the liver, and of the kidney; peritonitis; laparotomy; death.

Case XXII. Z., twenty-four years old. The patient was a robust man, who was run over on June 4, 1891. The fifth, sixth, and seventh ribs on the right side were fractured. There was emphysema of the skin, and moderate pain in the body, accompanied by frequent vomiting. An ice-bag was applied and opium administered.

On June 5, the abdomen was more distended and painful. The urine was of a light color, and voided spontaneously.

On June 6, the symptoms of peritonitis increased. The urine became red in color, and microscopically was found to contain red blood corpuscles.

A diagnosis of traumatic peritonitis was made, occasioned by injury to an abdominal organ—possibly either intestine or bladder, and on June sixth laparotomy in the median line, from the navel to the symphysis, was performed. About one liter of an almost black, yet fluid, blood was evacuated. The intestinal serosa was covered with a dark green coating. An examination of the bowel revealed no injury, and the bladder was intact. Between the intestinal folds there was a green fluid evidently containing gall, or small fragments of the liver. The abdominal cavity was drained and the wound closed. Death occurred during the evening of the day of the operation.

Autopsy: Fractures of the fifth, sixth and seventh ribs, an injury to the pleura, a T- shaped rupture of the liver, and a tear of the right kidney, were found. The intestine and bladder were intact.

FRUIT EATING.

The value of fruit of various kinds in the dietary of the average healthy individual cannot well be over estimated. When it causes indigestion it is usually because it is taken at wrong times, and not because it is necessarily difficult of digestion. The proper time to partake of fruit, whether cooked or raw, is at meals, and not, as is so frequently done, at odd times throughout the day. At this season of the year most persons are the better for restricting the amount of nitrogenous food and indulging in raw fruit and green vegetables. It must not be lost sight of that fresh uncooked fruit and vegetables ought to form a substantial part of our daily food. Cooking, though it may facilitate the digestion of fruit, does so at the expense of the peculiar quality of freshness the absence of which in the long run, gives rise to serious disturbances of nutrition. A belief has gained ground of late years, based on a misconception of certain general statements, that fruit is harmful to persons with a tendency to gout. No doubt if cooked and sweetened by the addition of cane sugar, dyspeptic disturbances are not unlikely to occur, but no possible drawback attaches to the use of raw fruit in proper quantities and provided that it is ripe. The salts contained in fruit are of the greatest value to the organism, aud are not obtainable in anything like the amount required from any other source. Children particularly should be encouraged to partake of fruit as part and parcel of their meals, and if proper care be exercised in the selection of a ripe and undamaged article, and in the giving of it at suitable periods, no disturbances of the intestinal functions need be apprehended. In conclusion, it is a generally-accepted maxim that fruit and alcohol do not go well together.—*Med. Press.*

A CASE OF KELOID OF THE MALE URETHRA.*

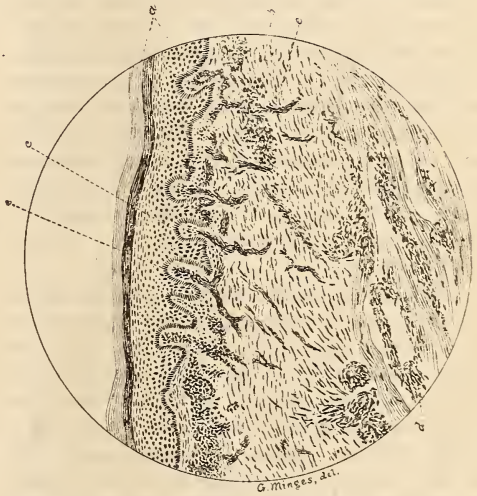
By GEORGE MINGES, M. D.

Keloid is a comparatively rare disease under all circumstances, but as an affection of mucous membranes it has been hitherto altogether unknown, at least as far as Dr. Mc Carthy and myself have been able to ascertain from a careful search of the standard works on skin-diseases and surgery, and from personal correspondence with several well-known dermatologists. Hence the request of this Society to describe this case for publication. Dr. Mc Carthy, being at present occupied by other very important matters, has kindly turned over his notes to me to allow of the completion of this paper in time for the meeting.

S. D———, aet, 33 years; Jew, married. Habits unexceptionable. Family history perfect. No venereal or other previous disease. Consulted Dr. J. S. Lewis, May 25th, 1890, on account of pain in the head of the penis and frequent micturition while on his feet, these symptoms being absent when lying down. Dr. Lewis thinks the patient had been to several irregular physicians before coming to him. Careful urinalysis and exploration of the bladder with a steel bougie of moderate size failed to reveal anything abnormal. Inability to pass a full stream became superadded during the following summer and the patient consulted an "irregular" who introduced medicated bougies which apparently aggravated the symptoms.

Soon after this, patient for the first time consulted Dr. J. F. McCarthy. The symptoms above described were now more urgent, but still absent in the recumbent position, and besides there was a feeling of weakness in the pelvis and lower extremities. Exploration of the urethra showed the presence of a stricture at the meatus, ¾ inch long, and allowing the passage of a No. 8 American (12 French) sound. An application of electrolysis alleviated the pain for three days and allowed the passage of a sound three or four sizes larger. Six or seven more seances of electrolysis were less successful and internal urethrotomy was substituted, allowing the passage of No. 20 American (25 French) sound, with which patient faithfully kept the stricture dilated. The cut healed by the formation of a dense, non-elastic tissue, without inflammation or suppuration.

Within four or five months after the urethrotomy the symptoms had again become so severe that Dr. McCarthy removed with the knife under cocaine the whole dense cicatrix. In two months the neoplasm had returned to its former extent, and Dr. McCarthy, now suspecting the growth to be of an epitheliomatous nature, sent the patient to me for a microscopical examination. I found a slight degree of epispadias, the result of the excision,



through which could be seen and felt a dense nodular mass involving the wall of the urethra, from which a smooth, unyielding scar seemed to extend almost around the whole circumference of the canal. A small piece was snipped out of the nodular portion with curved scissors and sections examined under the microscope, but as the subjacent tissues had not been included, a definite diagnosis could not be made at that time.

About six weeks later (Sept. 19th, 1891) a more radical operation was done by Dr. McCarthy, the urethra being split up for a distance of 2½ inches and turned out, and all of the neoplasm and a still larger portion of healthy tissue excised and given to me for microscopic examination. The new growth was hard and nodular and did

*Read at the annual June meeting of the Dubuque Medical Society, June 18, 1892.

not differ much in color from the surrounding urethra. After hardening in absolute alcohol and imbedding in celloidin, sections were made with a microtome perpendicular to the surface and stained with hæmatoxyline and eosine, and gave the picture shown in the cut.

The surface of the verrucose tumor is everywhere covered by a thick layer of tesselated squamous epithelium except in a few small places where it seems to have been mechanically removed by the manipulation resorted to while preparing the specimen. The rete mucosum (I will here designate the different layers of the mucous membrane by the names generally given to the corresponding strata of the external skin) is also apparently normal in every way, likewise the papillæ of the corium. The remainder of the corium consists of bundles of closely-packed fibres and spindle-cells, running parallel to the surface, traversed by numerous capillaries infiltrated with intensely stained round and spindle cells. The larger cells are likewise surrounded by aggregations of newly-formed cells. Roundish collections of young cells are also found in the corium independent of the blood-vessels.

The history of the results, of the several operations, leading to speedy recurrence and greater size of the neoplasm, together with the uniform direction of the new-formed tissue, parallel to the surface, the strict limitation of the fibrous hyperplasia to the corium without destruction of any of the normal elements of the mucous membrane, and the infiltration of the adventitia of the blood vessels, determined the diagnosis of keloid, in spite of the fact that that disease has been heretofore described as exclusively an affection of the skin, because no reason was apparent why it might not attack a mucous membrane, and especially that of the fossa-navicularis, which histologically differs so little from the integument. In accordance with that diagnosis the prognosis was made unfavorable as regards recurrence, because every excision, by increasing the size of the scar, must be followed by a corresponding enlargement of the neoplasm.

The prognosis was soon verified, for in two months patient was worse than ever. Dr. McCarthy now advised amputation of the penis, but this was not accepted. Mr. D— now passed into the hands of another physician who in time excised the growth still more extensively.

Dec. 16th, 1891, six weeks after the last operation, patient called upon Dr. McCarthy, and the scar-tissue was again returning and causing considerable pain.

March 10th, 1892, patient wrote from Grand Rapids, Mich., saying that he was still in the same condition, and that he could stand very little walking, as the irritation made his penis very sore.

THE ÆTIOLOGY OF PRIMARY CROUP.

In a recent work, F. Egidi and L. Concetti (*Archivio Italiano di Pediatria*, 1892–*Rev. Inter. de Bibliog. Méd.*, April 25, 1892) appear to have established an identity in the nature of primary croup and diphtheria. It seems that the dual theory of the disorders referred to, has made great progress in Italy, and that the majority of practitioners admit that croup is not as contagious as diphtheria. The authors show, from their studies, that we must go back to the original conception of Bretonneau and of Trousseau, and consider the two affections as two different localizations of the same disorder: diphtheria. Egidi puts forth the clinical reasons that sustain this theory. In a recent epidemic of croup observed in Rome, the patients, after being operated upon for tracheotomy or intubation, would succumb in the course of two or three days, with symptoms of adynamia. Concetti made cultures from the false membranes of such patients, and found the bacillus of Klebs-Löeffler. The cultures were inoculated into animals, causing in them all the symptoms of diphtheria. Upon 16 clinical patients suffering from primary croup, bacteriological examination revealed, in 14 of them, the bacillus just mentioned. This latter author, Concetti, then affirms that in the cases observed by him, the primary croup was of a diphtheritic nature in the proportion of 87.5 per cent. The negative results observed in the other two cases are explained by a defective maneuvre. Concetti describes minutely the process of cultivating the bacillus for examining and inoculating purposes. He further insists upon the fact that in from 24 to 48 hours, bacteriological examination constitutes an exact test in a doubtful case of croup.

A CASE OF TRAUMATIC ABSCESS OF LIVER AND PERINEPHRITIC SPACE, DISCHARGING THROUGH LUNG AND URINARY TRACT.

By JAY MUSSINA BRYAN, M. D.,
FOUNTAIN SPRINGS, PA.

Edward C—, aged 38, miner in the employ of the Lehigh Company, residing at Tamaqua, Pa., a moderate drinker, a steady worker, previously healthy. While driving a chute on May 7th was struck on the back by a fall of coal, forced about five yards down to the main chute, the coal sliding off during the fall. He was helped out and after a few minutes walked home, paying very little attention to his hurt at the time.

He kept at work for two weeks though troubled greatly with his side. A swelling in the right renal region then made its appearance and C—, was compelled to stop work and see a doctor. This individual put a large plaster on his back, encouraged him to get around as much as possible and go to work, even hinting that nothing was wrong with him. Under this treatment C—, worked three days and was compelled to go to bed. The doctor, finally persuaded that something was wrong, examined the swelling and informed the patient that he suspected "gravel in the kidney." At the expiration of a month, alarmed at his rapid loss of weight and strength, C—, discharged him and came to the State Hospital.

On admission June 7th the patient had the appearance of a dying man, his face almost bloodless, expression anxious, body drawn slightly to one side. In the right renal region was a rounded swelling, firm on pressure, too deep to be well circumscribed, in which fluctuation could not be detected. He had a severe cough attended with copious expectoration, but microscopic examinations of sputa showed no bacilli or elastic fibres, but few epithelial cells; consisting, indeed, of almost pure creamy pus and a little coal dust. On close questioning it was noted that the cough, while it was continuous for some time was but the anthracotic cough common to the miners of this region, until, sometime after his hurt, it suddenly became much worse and the expectoration greatly increased in amount. About the same time his urine became "milky" as he expressed it, and he felt much relieved for a few days. Microscopic examinations of the urine also showed pus, with no tube casts. Vague hectic symptoms were noted for three days and a conservative operation decided upon.

Operation.—On June 10th the patient was put on the table, a few whiffs of ether given and a small tenotome passed deep into the lumbar muscles over the swelling with a negative result. An incision was then made and the surgeon's finger was then forced through the muscular covering into the abscess cavity from which about thirty ounces of thick, ropy pus exuded. Digital exploration showed the under surface of the right lobe of the liver excavated as far as the finger could reach, the kidney much displaced but evidently intact and the whole perinephritic space distended beyond the reach of the operator's finger. The whole cavity was thoroughly irrigated with $\frac{1}{4000}$ warm bichloride solution and peroxide of hydrogen, a drainage tube inserted and the wound dressed antiseptically. The hectic symptoms ceased and the patient became much easier at once. The opening discharged pus freely for a week, necessitating a frequent change of dressings and irrigation. The discharge slowly lessened in amount, the tube being removed a week ago. The patient has never had an untoward symptom, the temperature never reaching 100° after the operation. He has gained greatly in strength and weight, the urine is free from pus and the cough all but gone. The case was complicated throughout by hæmorrhoids, but with returning health this condition has decidedly improved.

CREASOTE SYRUP FOR THE SODA FOUNTAIN.

Creasote is now prescribed so frequently for so many affections of the stomach and lungs that a Vienna pharmacist serves it from his fountain and has numerous customers for it. The following, according to the *Ztschrft. d. allg. Oest. Apot. Verein*, is the formula for the syrup:

℞

Creasote	1 part.
Cognac brandy	50 parts.
Simple syrup	300 parts.
Tincture of peppermint	2 parts.

Mix.

REPORT OF A CASE OF STENOSIS AT THE AORTIC ORIFICE; HISTORY, DIAGNOSIS AND TREATMENT.*

By DR. E. B. BORLAND.

This case is reported for your consideration and comment, on account of its being one of the rarer forms of organic change in the valve orifices of the heart, its murmur being frequently confounded with functional murmurs at the base, and its treatment being based on indications differing from the routine treatment of the other valve orifices or valve lesions.

Mrs. M., aged 63. Family history good, except some tendency to rheumatism in some of the other members of the family. She gives some history of chronic bronchitis in early life. Was married at the age of 46. Her first and only child was born after a difficult labor. General health good for the last 40 years preceding the present trouble, which began about two years ago, when she first noticed some shortness of breath on exertion and a little later on a short cough troubled her on rising in the morning. At intervals she complained of some uneasiness and pain in the region of the heart, and had frequent attacks of fainting. About one year ago she came under my observation with the following symptoms: Appetite poor, tongue moist, intensely red and deeply fissured. Tenderness over the stomach and some irregularity of the bowels. General appearance of anæmia and emaciation. Radial pulse so weak and compressible that it could only be counted with difficulty. Examination of the chest revealed the usual signs of chronic bronchitis. The impulse of the heart against the chest wall was not perceptible, and the position of the apex beat could not be determined by palpation on account of the feeble systole. The first sound of the heart, as heard over the mitral area, was very feeble, shorter than normal and absent in about one systole in twelve. The second sound, as listened to over the base, was preceded by a low pitched systolic murmur. The veins were more prominent than normal but no signs of dropsy. During last summer she suffered from the usual number of "fainting spells," followed by general prostration lasting for several hours to several days. These attacks were evidently excited by unusual physical exertion or chill. During their continuance the heart's action was weakened, the cough increased, cyanosis deepened and the tendency to syncope on rising much greater than usual. These attacks were treated with small doses of morphine or alcoholic stimulants. Digitalis was tried several times cautiously in small doses, but had to be discontinued on account of its increasing the dyspnœa and cyanosis, causing signs of pulmonary congestion and making the heart more irregular. Several preparations of iron were given to correct the general anæmia but were not well borne by the stomach. Teaspoonful doses of emulsion of cod liver oil given just before meals gradually improved her appetite and strength. The attacks of heart exhaustion became less frequent and less severe. In the early part of the winter she had an attack of acute bronchitis with a moderate rise of temperature, which yielded to the usual remedies. No other rise of temperature was noted; it being usually subnormal. Her condition at present is as follows: Tongue still red and fissured, digestion improved, urine normal in color and quantity, specific gravity 1022. No albumen nor sugar, reaction decidedly acid, precipitate containing an excess of lime salts. The radial pulse is tardy, small and beats about sixty to the minute, but is noticeably stronger than it was a year ago. The percussion wave of its tracing has a low amplitude, the ascent is more gradual, the apex more rounded and the descent more gradual than normal. No dicrotic waves can be detected with the finger, and there is no visible pulsations in any of the larger arteries. The pulse intermits when the cardiac sounds are absent. The temperature in the afternoon is about 97.5° F.

The physical signs of bronchitis have almost disappeared, but the respirations are still about 28 per minute. The cough is absent except on rising in the morning.

The area of percussion dullness cannot positively be determined on account of the mammary gland. There is no impulse in the fifth intercostal space either on inspection or palpation. The apex probably strikes the sixth rib. The first sound, as

*Read before the Allegheny County Medical Society June 21, 1892.

listened to over the mitral area, is shorter, higher in pitch, and has lost its booming quality. Over the aortic area, during systole, a harsh murmur is heard which is transmitted to the subclavian and cartotid arteries. No sound is audible over the aortic area at the time of the opening of the semilunar valves, but over the pulmonary valve area the closing of the semilunar valves of the right heart can be distinctly heard.

The clinical history of this case is one of atheroma of the aortic orifice, coronary arteries, and probably, to some extent, of all the larger arteries, with infiltration of lime salts, particularly around the aortic orifice. The age of the patient is in favor of atheromatous changes. After the aortic valves are closed there is no sign of a regurgitant murmur. This is evidence that the free edges of these valves approximate, and that there are no vegetations on their ventricular surfaces. The murmur heard over the aortic area during the passage only of the blood from the left ventricle to the aorta, is evidence of narrowing of the orifice or thickening of the bases of the valves so that they cannot be pressed into the sinuses of Valsalva, or both. The imperfect nutrition of the heart is shown by its feeble systole, intermittent pulse and lack of complete compensatory hypertrophy. These are signs that the openings into the coronary arteries are either obstructed or these vessels are in a condition of sclerosis.

The irregular intermittent action of the heart is not a necessary factor of simple aortic stenosis but is considered characteristic of diseased coronary arteries.

The aortic direct murmur is more likely to be mistaken for functional murmurs than any other abnormal sound. The latter is most frequently heard over the base during systole, and the anæmia and emaciation in this case would seem to favor the functional murmur. In simple anæmia murmurs the frequency and force of the heart's action increases during mental excitement or physical exertion; or, in other words, there is a marked temporary palpitation. In this case the heart's action is weakened and not noticeably increased in frequency under similar conditions. The pulse of anæmia is not only more frequent but is large and soft. In its tracing the percussion wave has a higher amplitude; the ascent is steeper; the apex pointed and the descent rapid. While the general health of this patient has improved and the other valves can be heard closing more distinctly than a year ago, the murmur has increased in intensity and pitch instead of diminishing. Functional murmurs are heard over the pulmonary as well as over the aortic areas but do not replace the normal sounds.

The use of digitalis was not permissible in this case on account of its main action being the stimulation of the cardiac inhibitory center, nerve, nerve endings and ganglia; thus slowing the heart still more by increasing the length of the diastole which robs the brain of sufficient blood during the intervals between the systoles to maintain consciousness and vital action. Further, digitalis markedly stimulates the vaso-motor nerve apparatus and contracts particularly the arterioles and delivery vessels, thus increasing the obstruction in front of the weakened, badly nourished left ventricle.

The treatment of the periods of heart exhaustion was based on two indications: Stimulation of the cardiac motor and accelerator nerves and ganglia, and removing as far as possible the obstruction to the outflow of the blood into the peripheral circulation. Morphine in small repeated doses (gr. $\frac{1}{16}$ to $\frac{1}{8}$) evidently increases the force and frequency of the heart by stimulating the cardiac motor and accelerator nerve apparatus. It relieves obstruction in front of the heart by relaxing the voluntary muscular system and dilating the vessels of the skin. Its action in congesting the brain relieves the tendency to syncope. It also depresses the respiratory center, and slows respiration which seemed beneficial in this case on account of the disproportion between the respiratory movements and the pulse beats. Alcohol, in small repeated doses, stimulates first reflexly and later directly the cardiac motor and accelerator nerve apparatus which increases the frequency and power of the heart's action. It also depresses the vaso-motor ganglia and center, thus dilating the peripheral vessels, causing the blood to flow more rapidly through them, and thus supplying the brain with sufficient blood.

In the general treatment, cod liver oil was given to increase the nutrition of the heart muscle. (For discussion see Society Reports.)

THE MEDICATION OF THE FUTURE.*

By ADOLPH KOENIG, M. D.,

The title of the paper I am about to submit is, I fear, of too great a scope to be allowed to stand qualification, for I do not presume to cast a therapeutic horoscope that shall lay bare the possibilities of scientific medication for all time to come. With the isolation of the chemical decomposition products of pathogenic bacteria and the induction of immunity against attacks of like germs, there is promise of a therapeutic revolution of the most sanguine in this age of wonderful progress. Standing on the threshold of this new field, I desire to limit myself to the time that shall elapse before the realization of the hopes generated by the labors of the bacteriologists in the physiological laboratory. The application of remedies in the general therapeutic proceedings now in vogue, is susceptible of much greater perfection, and until the knowledge concerning the life history of the pathogenic germs becomes better established, and all their manifestations made clear to the human understanding our attempts to preserve the lives of our fellow creatures, must be based on the present, more or less empiric lines of treatment. My remarks, therefore, should be considered as having reference in the main, to the present methods of medication, some of which, especially those directed toward the relief of functional disorders, will doubtless be resorted to, and exert their beneficial influence till such disorders, under the reign of perfect hygenic, social, political, and general economic conditions, shall cease to afflict the human family to the extent now prevailing.

A retrospective glance over the history of the application of medicine reveals wonderful progress within the last two hundred years, or perhaps the progress might more appropriately be limited to the present century, dating from the time that the isolation of the active ingredients of the drugs, derived from the vegetable kingdom, has made it possible to study their action from a physiological standpoint. Another powerful factor contributing to the progress in medication has been the disassociation of supernatural power from the effect of medicines. In the dark ages of religious domination, the little medical knowledge extant was found among the members of the priesthood, and it is thus not to be wondered at that they invoked the aid of, and attributed some of the effects of medicines to the influence of supernatural intervention. When it was finally discovered that the beneficial results could be traced to some special ingredient of the drug exhibited, independently of supernatural power, progress assumed rapid strides.

Allow me to substantiate this assertion by offering a few quotations from the Pharmacopœia Londinensis, written by Nicholas Culpeper, and published in the comparatively recent times of 1653. Under "A Premonitory Epistle to the Reader," he says; "God Himself, the only First-being, the Maker and Disposer of all things, Governs the Celestial World by the Intellectual, namely the Angels; He governs the Elementary World, and all Elementary Bodies, by the Celestial World, namely, the Stars; and that's the reason the influence of the Stars reacheth not to the Mind or Rational part of Man, because it is an Epitomy of the Intellectual World, which is a superior to them; but because there is is now some Dispute about it (I should have said Cavelling), by such as would fain have their own Knaveries hidden, and therefore they would fain have the Stars made to stop bottles, or else for the Angels to play at bowls with when they had nothing else to do, but not rule the Elementary world, no, by no means. We shall prove that they rule over the Elementary world, first by Scriptures, secondly by Reason.

"First, by Scriptures: I beseech you read in the first place, Genesis 1, 14, 15, 16, 17, 18, verses, * * * * To this place also answers that in the 136 Psalm. He made the Sun to *rule* by day, and the Moon and Stars to *rule* by night. In these Scriptures God saith He made them to Rule, He set them for Signs, therefore they must signifie something, He set them also for Seasons, for Daies, and for Years; the Scriptures are so clear, they need no Exposition."

Then the author says: "But let us see what Reason saith to the business." Reason he declares proves, among other things, that "both Sun and Moon make use of the other five Planets, (even as the Heart

*Read before the Allegheny County Medical Society, June 16, 1892.

and Brain make use of the Liver, Spleen, Gall, &c., in the Body of Man) for the effecting and varying things below, and tempering them diverse waies according to their several motions, else the things generated in the Elementary World would be of one Nature and Quality, and then the world could not subsist; for Man having all qualities in him, cannot subsist without any one of them. He, and he only, is a Physician that knows which of these qualities offends, by which of the Celestial Bodies it is caused, and how safely and speedily to remedy it; all the rest that practice Physick are but Mountebanks, for there is no question to be made, but that all Diseases have their original from super-aboundance or deficiency of Heat, Coldness, Dryness or Moisture; and that the Elements barely from themselves can cause this, is an opinion more fitting for a Hog-herd than a Phylosopher."

This and much more he says, "is evident to the experience of them that search after it." With such belief in the influence of the celestial bodies we may safely expect nothing short of the miraculous from the administration of his remedies, and in illustration of this a single quotation will suffice; it is as follows: "Burdock, temporarily dry, etc. Also *Mizaldus* saith that a leaf applied to the top of the head of a woman draws the matrix upwards. but applied to the feet it draws downwards, and is, therefore, an admirable remedy for suffocations, precipitations and dislocations of the matrix, if a wise man have but the using of it."

The transition from such blind practices to the administration of medicines for their physiological or germicidal action was necessarily a gradual one, and even at the present time among the ignorant, the old-time beliefs are not frequently encountered. Indeed many of them imagine that he who treats their ailments on scientific principles, and makes no claims but what he can prove by facts, which unfortunately, however, they can often not understand, is deficient in knowledge and ability to cope with disease. The charlatan who takes advantage of his patient's ignorance in making a diagnosis of typhoid fever where the honest physician declares his inability to immediately decide between that disease and some obscure temporary gastric or hepatic derangement, and then claims to have "checked" the fever when nature has repaired the damage, receives more credit than he who always tells the truth—at least for a season.

Then again look at the prodigal sons who deserted their father's house to prey on the ignorant, by clothing their remedies with so dynamically subtle and forsooth, even spiritual powers, that their elder brothers, with less keen perceptive powers, are unable to appreciate their modus operandi. Doubtless when knowledge shall be more widely diffused, and the true value of dynamic and spiritual attributes of medicines recognized by the people, and the prodigals reduced to a diet of husks, they will return to the fold where their brothers have continued to aid nature by natural means.

The empirical use of medicines generally rests on some well-marked action which the substance induces; and it is a source of great wonder to note how crude substances of very different origin, but possessing identical, or closely-related ingredients, have been used with the same end in view by different peoples.

The desire for a stimulant to the mental faculties is an attribute normal to all the members of the human race, be they high or low in the scale of development. This craving, it was discovered, in the case of the Chinese and Japanese, is satisfied by the use of an infusion of the leaves of Camellia Thea; by the Arabians by the use of a similar preparation of the seeds of Caffea arabica. The seeds of Cola acuminata served the same purpose for certain barbaric tribes of tropical Africa; in lower South America the leaves of Ilex paraguayensis enter into a stimulant beverage used by the aborigines, called mate; on the banks of the Orinoco a tribe of Guaranos make a paste from the seeds of Paullinia sorbilis, called Guarana, which is the base of another stimulating beverage; finally, even our native Indians may be cited as an example. In some of the Southern States they were known to make a decoction of the leaves of Ilex Cassine, a species of holly, called "black drink," which was drunk during the performance of ceremonial dances.

The wonderful part of these customs only becomes evident after the chemists inform us that the active ingredient of each of the substances named is caffeine, or else an alkaloid having an almost identical chemical formula.

In the same manner numerous antispasmodics may be shown to depend for their popular reputation on valerianic acid; in this category belong viburnum, sumbul, lupulin and valeriana.

The favor with which mineral products and synthetic chemicals have in recent years been accepted, undoubtedly rests on their definite composition, and the use of the old galenical preparations has decreased because they are diametrically indefinite in active constituents. The time will, doubtless, soon come when the physician who administers active drugs, not in the form of their active constituent, or in the form of assayed preparations, will be held equally culpable with the surgeon of the present time who would be so negligent as to use an aseptic solution of bichloride of mercury or other germicide, without assuring himself of the percentage strength of the active material. Isolation of all valuable constituents of crude drugs, wherever the present chemical knowledge admits of such preparation, must, therefore, precede accurate dosage, and under the wise patronage of the English and French governments, where research in this direction is fostered, much may be hoped for from numerous investigations now occupying the attention of European chemists. With active ingredients we may always expect definite results; never have I failed to cure a case of true malarial fever with a salt of quinine, and my experience ranges from the deadly Chagres to the common forms of quotidian and tertian fever. Who has ever failed to obtain the typical anodyne effects of the best crude opium from morphine, and who has not been disappointed in laudanum? Not only does morphine represent the anodyne, hypnotic, antispasmodic, and other valuable properties of opium, but the antagonistic action of such alkaloids as thebaine and narcotine is eliminated. Who has ever failed to recognize the excito-motor effects of large doses of chemically pure strychnine? In this connection I might refer to a thesis submitted by a member of the recent graduating class of the Pittsburgh College of Pharmacy on tincture of nux vomica. Out of ten specimens bought at random from as many sources only one conformed to the pharmacopœial requirement in percentage of solid extract, and the yield of alkaloids was equally variable. Defective preparation and variability in the crude drug, probably both contributed toward this result.

Modern investigation and discoveries have widened the field of medicine to such an extent that division of labor is an absolute necessity, and the most needful specialty is that of pharmacy—the preparation and dispensing of medicines. Unfortunately this specialty is far from being perfect, but nevertheless it possesses, even in its present condition, many advantages over the new idea, or more properly the old one, that physicians should apply medicines without the intervention of a skilled pharmacist. This resurrection of the ancient methods of administering medicines may be traced partly to the blandishments of the gentlemen who preach "elegant pharmacy," so that the consumption of medicines may assume the form of a luxurious habit, and the revenues of the manufacturer proportionately increased, and partly to the delusion that the regular practitioner must compete with the homœopaths, as if competition in any form entered at all into the work of the conscientious physician. No one conversant with the training and skill needful for the proper performance of the work of the pharmacist in assaying, testing, preparing, and dispensing of medicines will fail to recognize the unfitness of the practitioner of medicine to do this work. This view is evidently taken by the State, for everyone desiring to engage in this work must submit evidence of fitness, while the wholesale manufacturer prepares and furnishes to the physician, tablets, triturates, without government supervision, and furthermore, these preparations are generally so combined as to render them less susceptible to the usual tests for purity of the active constituents. For a physician to carry and dispense his own medicines is manifestly improper; it is improper because he cannot carry in stock all he needs, especially when it is remembered that many drugs must be used soon after being prepared, because of rapid deterioration, and to use complex tablets where the dose to be exhibited in the disease for which they are intended, is fixed by the wholesaler without reference to the individual requirements, is, to use a mild expression, unscientific. Besides, what physician in active practice could furnish his patients with the various officinal acids, alcohols, spirits, volatile and fixed oils, not to men-

tion the numerous other preparations requiring frequent renewal, or presenting difficulties in manipulation?

The demands of scientific medication, in my opinion, warrant the following summarized conclusions:

1st. All medicines should be prepared and dispensed by chemically skilled, licensed pharmacists.

2d. All mineral products should be in absolute purity, and all drugs of vegetable origin, with marked medicinal action, should be exhausted of their active constituents, and these administered in either their isolated condition or in assayed solutions or triturations.

3d. Pharmacopœial requirements and tests for the purity of drugs should receive legal support, and in the case of perishable substances there should be a period, fixed by law, after such drugs should no longer be dispensed.

4th. Any drug possessing marked medicinal action, offered for sale by a pharmacist, should be subject to examination by government chemists, and adulteration or other defective conditons render the vender amenable to the law, as partly contemplated by the provisions of the Paddock Pure Food and Drug Bill.

5th. To protect the public from unscrupulous and designing practitioners physicians should be prohibited by law as is the case in certain European countries, from dispensing medicines, except in cases of emergency and in localities remote from medicinal supplies.

6th. Substances possessing curative properties should be free and unprotected by letters patent, trade mark, or proprietorship; on the other hand the government should foster investigations and reward discoveries of valuable curative drugs.

(For discussion see Society Reports.)

A DEPILATORY POWDER.

According to the *Bulletin of Pharmacy* for February, 1892, the following is a useful depilatory powder:

℞ Sulphide of barium.....50 parts.
Starch.
Oxide of zinc, of each.....25 parts.

This is mixed with water so as to form a soft paste and spread upon the face. In ten minutes' time it is scraped off and the skin is now found to be smooth.

Society Reports.

ALLEGHENY COUNTY MEDICAL SOCIETY.

Scientific Meeting, June 21st, 1892.

D. C. Huffman, M. D., Vice President, in the Chair.

Dr. E. B. Borland read a paper on "Stenosis of the Aortic Orifice" etc. (See page 332.)

DISCUSSION.

Dr. Lange: The case reported by Dr. Borland is very interesting, inasmuch as it is reported as a case of pure aortic stenosis, which condition is exceedingly rare. Stenosis alone is an exceedingly rare form of the disease, so exceedingly rare that when met with, the physician is at a considerable loss as to the advisability of the usual remedies for loss of compensation, which, however, from the report in Dr. Borland's case, did not exist. This patient, if I understand the description of the case correctly, was, and for many years has been, an anæmic. The patient never gave any indication of rheumatism, one of the most common causes of valvular disease, and it is no evidence, although she came from a rheumatic family, that she had it. The fact that this patient could not take digitalis is interesting, for when a patient has loss of compensation and can not take digitalis, then the prognosis is extremely bad. Of course we have our little list, digitalis, strophanus, caffeine and convallaria, but in spite of this list, which might be increased by remedies which are not on my tongue, when a patient cannot take digitalis, then the prognosis is extremely bad.

There are two classes of patients who cannot take it, and the case reported by Dr. Borland to one of these classes properly belongs. The patients who cannot take it are those who have aortic insufficiency with the large, jumping, bounding pulse of insufficiency; the patient cannot take digitalis, but when we do give it, such a patient requires particularly close attention. The other class of patients who cannot take it are those whom it nauseates, and if persisted in it would throw them into colic. In the case reported by Dr. Borland, the symptoms did not indicate the administration of digitalis. There

was no loss of compensation. It is stated she had some shortness of breath. That is probably always present in such patients, even where dropsy has disappeared. Shortness of breath is a common thing with patients before the appearance of dropsy.

Dr. W. C. Shaw: In some cases of examination for life insurance I have noticed where the party has had no history of rheumatism at the time of examination, on questioning his parents at home he was found to have had rheumatism when an infant, and that often accounts for the fact of valvular lesions without a history of rheumatism. Rheumatism in infants occurs oftener, I believe, than is recognized. I have in my mind now an agent for the insurance company who had valvular disease of the heart, and never supposed he had rheumatism, until after some years, when he had been rejected once or twice, his mother told him he had had rheumatism when an infant.

Dr. Borland: Dr. Lange must have misunderstood my report of the case in regard to compensation. There were signs of loss of compensation when I examined the case first, and at the present time there are slight signs; also a number of signs of dilatation are present at this time. The doctor also spoke of not using digitalis in aortic insufficiency, though it was indicated in aortic stenosis. My experience in aortic insufficiency has been that it will bear digitalis better than the obstruction of the aortic orifice. Rapid pulse with low tension is, as I understand it, an indication for the use of digitalis.

Dr. Adolph Kœnig then presented a paper entitled "The Medication of the Future." (See page 334.)

DISCUSSION.

Dr. Buchanan: I agree with most of what Dr. Kœnig has said, but with regard to the fifth article of his summary, I wish to enter my protest. I would be very sorry to see the day when the medical profession was prevented from carrying their own hypodermic tablets. I would be excluded from doing so, as I understand it, by the gentleman's article. I will extend my objections to morphia for administration by the mouth. I will extend it to every drug that a physician finds necessary or desirable to carry. I believe that the physician has exactly the same chance to get a good and reliable preparation as the retail pharmacist has, and I see no reason why a middle man should come between. I do not dispense my own medicines simply because I do not find it convenient, I would feel I was very much injured if the Government or State stepped in and debarred me from that purpose. I believe that a large number of very good practitioners carry their own medicines and dispense them with satisfaction to themselves and with advantage to their patients and when we can get morphia and strychnine, and dozens of other remedies which we daily use, put up in compact and reliable form in measured doses, easily dispensed, when a man's practice is of such a nature that it is convenient for him to dispense them, I think it is the right and safe thing for him to do. It is a little more trouble very likely, but for a certain kind of practitioner it is the right thing to do. I think Dr. Kœnig is mistaken in his article upon that point.

Dr. Batten: Dr. Holmes stated that if all drugs, with but a very few exceptions were cast into the ocean, it would be bad for the fish, but good for humanity. I believe Dr. Holmes was right to say what he said from the manner in which drugs are dispensed and given to the public. The druggists talk medicine over the counters. The doctor talks medicine at the bedside and the ladies understand pretty near as much medicine as the doctors do, and consequently they are constantly dosing themselves in medicines and to their own hurt. I believe there ought to be some means taken by which the lady could be prevented from taking medicine, except when prescribed by a competent physician. There has not been very much progress made in the way of medication for the last fifty years. It is true that the physicians of fifty years ago prescribed better than they knew, yet we know at the present time that they prescribed certain medicines and that we prescribe the very same medicnes in the same diseases that they did fifty years ago. There has been some increase in the drugs, but the number of drugs that are used now will not very much more benefit the patient in certain cases than those used fifty years ago. For instance, take mercury. We use mercury at the present time in all germ diseases. They used it fifty years ago. We use the drugs now because we

know they are germicides, they used mercury fifty years ago because they knew these drugs benefited their patients. I think the doctor is right when he says that the only place to write a prescription is at the bedside, and I have no doubt physicians who carry their own drugs often cheat the patients out of drugs, but when we prescribe at the bedside and write our prescriptions there we have written a prescription which we believe will benefit our patient and we do not get into a routine kind of treatment. I believe in progressive medicine, but I believe that preventive medicine will finally outstrip curative medicine or curative drugs, and I believe the time will come when our country is inhabited by twice as many millions of people as it is at the present time, malarial fever no doubt will be rooted out, the poison will be gotten rid of and we will have no malarial fever and as our young people are educated at our common schools and institutions of learning to study and know the value of preventing disease, the more these diseases will decrease and the better they will know how to take care of their systems and bodies and less medication will be needed.

Dr. Davis: I want to say as far as I understood the Doctor's paper, there are a great many good points in it. The first part of the paper seemed to recount to us the unfortunate ignorance of the past and all seemed to glory in the fact that chemistry had come to the aid for better pharmaceutical preparations. The last part of this paper seemed to throw this all away by saying the physician had no right to use for his own benefit the very things that would come in, but that he must relegate this to second-hand parties. I do not quite see the logic of his paper therefore, what the first part had to do with the last. The way Dr. Kœnig rejoiced that chemistry had come to our aid and succeeded in bringing many of the drugs of the past to us, put in the physician's hands in a plain and simple form, medicines easy of administration, rapid and certain of action. This being the case, I do not see why that physician should be called upon to go to somebody else to administer his medicine for him which has already been prepared by the chemist. As the alkaloids are so very much better, which he illustrated, and as strychnine can be administered in divided doses by a doctor as well as anybody else, I do not see the logic of his paper. If the paper had started the other way, had asserted that all of these complicated formulas of the past were the formulas that ought to be used in our medicine now, then I could see the logic of his paper, as the preparations are so complex and compound, it is neccessary to have somebody else to compound them for us. Practically I think every physician will be guided entirely by what he finds will be the most convenient for him and the best for his patient. He will be wedded to no theory, no scheme, except what he finds answers his purpose in curing those that are afflicted and he will not strive after any better scheme, but fully and frankly use what seems the best in itself. Indeed there are very many cases we are called to see which need almost instantaneous relief. Take for instance cholera morbus. I care not whether it is next door to a doctor. You find a patient suffering from cramps. By the time you write out a prescription for a little bit of morphia, ring up the druggist, and get him to analyze it to see that it is fresh, by that time I think the patient would really wish you had some of the drug with you to administer on the spur of the moment and get relief. I know the doctor excepted emergencies, but I do not know of any case of sickness which is not an emergency. It is always an emergency and the sooner they have the remedies the better, and the sooner the doctor sees they have the remedies the better. You send to a drug store, they do not have the remedy on hand, and you have to send to another. Even where the patient is not in pain you have often lost valuable time. I believe drug stores have their legitimate place, their proper place, but unfortunately for the status of medicine to-day, the drug store has drifted from the position it ought to have. The drug store of to-day is the dispenser of patent medicines, and all in this city, with possibly one exception, dispense all the nostrums that are advertised broad and and wide in the land. That seems to be their avocation. They certainly assert that it is the source of their main profit. I am certain that anything that would lead them out of this practice would be better for the general health of the community. Now the other point that Dr. Batten made in regard to the remark of Dr. Holmes,

has the same logical conclusion. If the physician does not write out a prescription he can carry with him the medicine that will take its place. In my days I was brought up to prepare all my preceptor's medicine. Everything he prescribed was prepared in the office, and I think it was one of the best advantages to me. I first practiced in Dayton. When I went there, there was not a physician who did not prepare his own medicines, and had them in his own office. They went to the retail drug stores, bought and paid for them and dispensed simply for the convenience of their patients, and it was in the city not the country. Now, the reason why so many in the city got out of the habit of using their own medicine, was the inconvenience of it, the length of time it took. For instance, if you wanted to prescribe quinine, you had to sit down and had to measure out so much Peruvian bark and put it in. It takes time and you could count out one or two dozen pills more rapidly than you could write a prescription. You would know how fresh they were and the exact weight, you could have all that thoroughly yourself, whereas you send a prescription, it goes to the drug store; you do not know how long they have them on hand; you do not know what grade they are, whether sugar or gelatine coated. They fill your prescription. If you write for two grains of quinine, the law requires that they shall give two grains of quinine, not Park, Davis & Co., or any other, and they fill it as they want to. This subject is full of interest. I practically think it comes down to this. Each one will in the future use exactly what they find is the most convenient and gives them the best results. If it is more convenient to write prescriptions they will write them, if it is more convenient and they get better results, they will carry their medicine with them. I do not think the time will come when they will carry all medicines. There is a legitimate field for the druggist and as long as he remains in that field, I think he will have the hearty co-operation of the physicians to sustain him.

Dr. W. C. Shaw: In using the prescriptions I feel more independent. Then I have my prescriptions written and sent to a druggist, just as the doctor says, on the very day. Then I have fresh drugs prepared with reference to the patient's age and other conditions, and am not tied down to a single tablet or to a single combination or any combination, and I think there is more freedom in the prescription than in the other. I have had a few tablets brought in for temporary use in the office, but I have not been able to serve my patients with them yet, I never have had the same freedom in prescribing, and I do not think I could dispense my medicines and have the same effect.

Dr. Kœnig in closing the discussion said: Drs. Buchanan and Davis, apparently, have applied a too restricted sense to my statement, "except in case of emergency." I have no objections against any one carrying morphine or other necessary substances for bedside administration, but I do object to the idea that a good physician can be a good pharmacist. The field of medicine is two wide for one individual to give personal attention to the necessary details in all the departments. Who would seek the advice of an oculist in an obscure gynecological case? Dr. Davis has certainly strengthened my position by his reference to the good old time when his preceptor dispensed all his remedies, but found it necessary to press into service his student, who, unless very different from other old-time office students, was utterly destitute of pharmaceutical knowledge. One of the weak points in medical education is, that pharmacy is not taught in medical colleges. Were medical students given an insight of the needful knowledge required for the proper preparations of remedies, they would hesitate, as physicians, to assume the responsibilities of pharmaceutical manipulation, just as in the case of chemical analysis. When a physician prescribes quinine pills, ready made, he cannot well assure himself whether or not the bulk of the alkaloid is true quinine or the inferior cinchonine or cinchonidine, but when he calls for the separate active principle he may require of the pharmacist tests for the purity of the drugs before he incorporates them in the pill or dispenses them in any form. Dr. Davis declared that every case of sickness is a case of emergency: If that is true, then Dr. Davis should never leave his office in response to a sick call without a supply of cod liver oil and whiskey, for is it not likely that he may be asked to the bedside of an emergency case of consumption?

The information gained from a messenger is often misleading and when the dispensing physician arrives at the bedside, equipped for what he expected to find and then discoveres the true condition, he will be sorely tempted to give the next best thing. It is not *convenient* to return home for the proper remedy, so he gives what he hopes will probably do almost as well as what he would have given had he relied on his pencil to procure the best remedy known to science and best suited in every respect to the demands of the case. I stated in my paper that the present condition of pharmacy was not an ideal one; that is evident to every one. Nor is the present practice of medicine satisfactory. We can point to many members of our profession who are not ornamental, and until human nature in general becomes somewhat remodeled or the government assumes control, we need expect these conditions.

The fault, however, is not all on the side of the pharmacist. Let us accept the fact that pharmacy is a legitimate specialty of medicine. Let us accord to pharmacists what is their due and let us *demand* of them that they confine themselves within the true limits of their specialty. The witty and jocular saying of Dr. Holmes about casting all medicines into the sea, quoted by Dr. Batten, requires no serious answer.

TREATMENT OF POISONING BY COCAINE.

Eloy gives the following directions for the treatment of acute poisoning by cocaine. The patient is placed in a horizontal position in order to prevent syncope, and his face bathed in cold water. If convulsions come on cold should be applied. If asphyxia is present flagellation, massage and artificial respiration are resorted to, and if the respiration depends upon the tetanic contraction of the respiratory muscles inhalations of chloroform are employed. For the intense pallor it is well to give inhalations of nitrite of amyl. Should these means be insufficient, it may be well to administer strong coffee or caffeine, or if swallowing is impossible, hypodermic injections of ether. The entire object of the treatment is to moderate the reflex excitability of the nervous system, to sustain the heart, and to re-establish the equilibrium of the circulation.

Selected Formulæ.

FORMULA FOR THE ADMINISTRATION OF OIL OF TURPENTINE.

Prof. H. C. Wood calls attention, in the *Therapeutic Gazette*, to the powers of glycerin in disguising the taste of turpentine, and gives the following formula:

℞ Olei terebinthinæ.....fl. ʒij.
Glycerin.....fl. ʒj.
Mucil. acaciæ.....fl. ʒiss.
Aquæ menthæ piperitæ.....q. s. ad. ʒviij.—M.
Sig.—Tablespoonful every four hours during the day. Shake well.

TREATMENT OF ATROPHIC NASAL CATARRH.

Flatan (*Weiner medizinische Wochenschrift*, No. 8, 1892), describes his treatment of the above affection in the following manner: The larger masses of secretion are loosened by means of a dull or small pointed sound, and then removed by forceps. The nose is then sprayed with a ten or fifteen per cent. solution of peroxide of hydrogen, and the small loosened waves either blown out or taken out with forceps. The nasal cavity is then plugged with ten per cent. iodol gauze, which has been passed through a mixture of vaseline, lanoline and paraffine. He covers the gauze with an ointment made as follows:

℞ Sozoiodol of zinc..... 10 grammes.
Vaseline.
Lanoline.....āā 400 grammes.
The treatment should be practiced daily from four to six weeks.

—*Univ. Med. Mag.*

A RESOLVENT GLYCEROLE.

L'Union Médicale for December 24, 1891, recommends the following prescription as an application to be placed over strumous glands at the same time that cod-liver oil is taken internally with a tonic and stimulant treatment:

℞ Iodoform.....gr. xxx.
Balsam of Peru.....ʒss.
Glycerin.....ʒvi.

SOLUTION OF MORPHINE.

A solution of morphine, 1 : 30, may be kept in the following solution for months without change (*Deutsche Med. Zeitung*, No. 29, 1892):

℞ Hydrochlorate of potash.....gm. 1.
Spirits of wine.....gms. 5.
Glycerine.....gms. 10.
Distilled water.....gms. 15.

INHALATION IN WHOOPING COUGH.

℞ Thymolis.....gr. xx.
Acid carbolicis.
Ol. sassafragis.
Ol. eucalyptus.
Picis liquidæ.
Ol. terebinthinæ.....āā f ʒij.
Ætheris.....f ʒiv.
Alcoholis, q. s. ad.....f ʒiij.
M. Sig.—Put about 30 drops upon a pad of such size as to be conveniently hung around the child's neck, renewing the application every two or three hours.

In severe cases the inhalation treatment is supplemented by the internal administration of:

℞ Acid carbolic.....gr. iij.
Sodii bromid.....gr. lx.
Tinct. belladonnæ.....gtt. xx.
Glycerinæ.....f ʒiij.
Aquæ, q. s.....f ʒij.
M. Sig.—f ʒij occasionally for a child 3 or 4 years of age.

—*Jour. Amer. Med. Assn.*

TRUSS DUSTING POWDER.

De Garmo, according to the *Annals of Hygiene*, recommends highly the following, not only for use with trusses, but wherever a toilet powder is used for children:

℞ Powdered starch.....ʒiv.
Powdered talc.....ʒij.
Dried alum.....
Powdered boric acid.....} āā ʒij.
Carbolic acid.....
Oil of lemon.....} āā ʒss.—M.

PASTA CERATA.

This is the name, according to the *Chemist and Druggist*, of a new ointment basis lately introduced in Germany. The paste is made by heating 3 ounces of yellow wax with a solution of 54 grains of caustic potash in 5 ounces of water. The wax is first melted, and the alkaline solution added, stirring well until a uniform mass is obtained. The potash is just sufficient to saponify the cerotinic acid, and the soap formed emulsifies the rest of the wax. The mixture is allowed to stand for two days, then it is passed through an ointment mill. whereby it acquires the requisite smoothness. Dr. M. Radziejewski, a leading Berlin eye specialist, prescribes a marvelous eye salve, made by a leading Berlin apotheker, which has the pasta cerata as a basis, and is said to consist of the following:

℞ Hydrargyri oxidi rubri..... 1 part.
Zinci oxidi..... 2 parts.
Camphoræ..... 0.5 parts.
Acidi aseptinici..... 2 parts.
Cocainæ hydrochloratis..... 2 parts.
Pastæ ceratæ ad.....100 parts.—M.

HÆMORRHOIDS.

℞ Atropinæ sulphat..... .....gr. iv.
Acid. tannic.....gr. vj.
Morphinæ sulphat.....gr. vj.
Cocainæ hydrochlorat..... .. gr. xxx.
Vaselin.....ʒj. M.
Fiat unguentum.
Sig.—Apply a small quantity to the hemorrhoid after each stool.

—*Rev. de Thér. Gén.*

SWELLINGS ABOVE THE CLAVICLE IN EXOPHTHALMIC GOITRE.

In his *Studies of Old Case-books*, Sir James Paget refers to a few cases he has seen where a swelling occupies the supraclavicular fossa on one or both sides. He looks upon this swelling as a localized myxœdema, but it has sometimes been regarded as a fatty tumor. Paget's cases were all in adult women, many of whom were neurotic, and suffered aching pains in the affected parts. In some of them the tumor diminished in size after a time, and remained permanently less; but a striking feature in all was the way in which they became "puffed up," and then contracted again as the pain increased and diminished at frequent intervals.

Arthur Maude, writing in a recent number of the *Practitioner* on "Œdema in Graves' Disease," describes an unusual form which he terms "transitory," inasmuch as it may last only a few hours. The dropsy takes the form of a puffy swelling of the face, neck, upper limbs, or both limbs of one side, the favorite localities, however, being the cheeks and eyelids. There may be no goitre and no exophthalmos, though the rapid pulse, tremors, and other neurotic phenomena may be present. In connection with the same disease, Rendu describes an œdematous swelling which he has met with in both supraclavicular fossæ in several cases, and he remarks that it seems to occur chiefly in neurotic women, and to depend on a disordered innervation of the cervical region. Potain has called attention to this phenomenon at a much earlier date. It is just possible that some of Paget's cases may have belonged to the same category as those last referred to, and that the relatively slight character of the general symptoms may have led the patients to consult a surgeon on account of the swellings in the neck, though these were really part of a more general malady which usually falls to be dealt with by the physician.

THE

MEDICAL and SURGICAL

REPORTER.

ISSUED EVERY SATURDAY.

DIRECT COMMUNICATIONS TO
P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor.
(Professor of Physiology, University of Penna.)

BUSINESS OFFICES:
29 to 35 North Tenth Street, Cor. Filbert.

EDITORIAL OFFICE:
Southeast Cor. 36th and Woodland Ave.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00

REMITTANCES should be made payable to THE MEDICAL AND SURGICAL REPORTER, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

—o—

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates)....$1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt "**The Medical and Surgical Reporter**" and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts.....$1.50 each.
Bovine Points or Quills..... 1.00 a doz.
Humanized Crusts..... 1.00 small.
Humanized Crusts..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

COCAINE AND ITS DANGERS.

The frequent reports of alarming symptoms or death from cocaine warrants our again calling attention to the dangerous character of this drug.

At a recent meeeting of the French Surgical Society of Paris, a discussion was opened regarding the *pros* and *cons* of cocaine either as a local anæsthetic or otherwise. Special attention was given to a consideration of what minimal hypodermic doses had produced toxic symptoms, and in connection with this the possible dangers incurred by even small doses.

Quite a number of the members were able to give results of their personal experience, and many interesting data were thus obtained. For the benefit of our readers we quote the following, deeming them of special practical interest.

Ruénu had used cocaine as an anæsthetic in all of 67 minor operations, including principally the excision of epitheliomæ of the lips, circumcision, hydrocele, etc. He injected from 3 to 7 centigrammes as a rule and frequently observed symptoms of intoxication which, however, disappeared after some time without serious consequence. Severer symptoms were once observed in a case of the radical cure for hydrocele, in which instance 5 centigrammes were injected into the skin and about 1 centigramme injected into the tunica vaginalis. The toxic manifestations were the following: Contraction and anæsthesia of the extremities, labored respiration, enlarged pupils, and finally threatened syncope. All these symptoms disappeared soon, except the weakness, which continued for some time. Ruénu closed his part of the discussion with the admonition that more than 10 centigrammes of cocaine should never be used for local anæsthesia if used hypodermically.

Schwartz had used cocaine over three hundred times as a local anæsthetic and

had never had a case of poisoning. To be sure he used only very small doses, especially when operating on or around the face, head, or trunk. When using the drug upon the extremities he always first applies an Esmarch's bandage in order to hinder the rapid diffusion of the drug. In the extremities he used from 5 to 7 centigrammes but in operations about the head or trunk never more than 5 centigrammes, and regarding this as a strictly maximal dose. The size of the dose, claims Schwartz, should differ materially with the location of the operation, and with the susceptibilities of the individual to be operated upon. In any case, however, it should not, in his opinion, exceed seven or at the most eight centigrammes.

Regnier follows in Schwartz's footsteps regarding the use of only small doses. Those usually employed by him ranging from 0.04 to 0.05 gramme. He has only observed to act in a untoward manner in patients troubled with cardiac affections. In these, indeed, the drug cannot be used too cautiously. Once he injected one centigramme in a patient suffering from cardiac dilatation and the patient was threatened with fainting. A similar dose —one centigramme—was injected into a patient suffering from mitral insufficiency, for the purpose of causing anæsthesia prior to the extraction of a tooth. The symptoms produced were progressively as follows: pallor of the face, slowing of the pulse, asphyxia, and deep unconsciousness. All these symptoms rapidly disappeared, but other cardiac complications ultimately increased and the patient died within a month.

Reclus, the well-known writer, pointedly asked whether indeed there were any subcutaneous dose of cocaine which could be used with absolute safety, and went so far as to even suggest the advisability of discarding the drug from the practice of surgery as unsafe and dangerous. According to his investigations of the subject he has found that in all fifteen deaths from the use of cocaine have been reported in medical literature. Of these two at least should at once be set aside; in one 1.60 grammes and in the other 1.50 grammes were exhibited internally. Three more of the cases included in the above fifteen cannot either be counted among the casualties resulting from the legitimate use of the drug, since in these the drug was inhaled in form of vapor or spray in solution, and the quantity of cocaine that was absorbed could not be accurately determined. This mode of using the drug should, by the way, in our estimation be entirely discarded.

There remain, therefore, nine fatal cases on record following the use of cocaine.

Five of these may be again excluded on account of the enormous dose employed, viz., 0.50 to 1.50 grammes hypodermically. In two fatal cases reported by von Berger the hypodermic dose was 0.38 grammes, and in a third also with a lethal ending 0.22 grammes of cocaine.

We now know therefore that injections of 0.22 gramme of cocaine should never be employed. In point of fact, however, much smaller doses are sufficient to produce local anæsthesia. Doses even of 0.20 gramme are not only dangerous but entirely superfluous. Large operations such as gastrotomy or castration can be painlessly performed after the injection of 0.12 gramme of the drug.

Now it is a fact that two cases have been published in which doses of less than 0.10 gramme have resulted fatally. In one of these—that of Abadie—the patient was a sickly man, seventy-one years old, in whom 4 centigrammes of the drug were injected into the eyelid. In the second case reported by Bouchard the dose was surely not smaller than 0.10 gramme, and in this case the heart of the patient was not normal.

Six centigrammes of the drug dissolved

in 2 grammes of water, will be found amply sufficient to completely anæsthetize quite an extensive operative field. All the same, even such injections must not be made directly into the vessels, not into the serous membranes, since in the latter the absorption is very rapid.

Two years ago Pozzi called the profession's attention to the fact that not more than 5 centigrammes of cocaine should be used hypodermically for surgical purposes.

Lucas-Champonniére at the meeting above referred to, expressed the wish that the discussion in question should be given as great a publicity as possible, so that practicing physicians should be brought to fully realize the possibly grave dangers attending the indiscriminate or even unguarded use of cocaine. The use of cocaine is so extended, especially on the continent that there is scarcely a tooth pulled or a cup applied without its being called into requisition. Explicit data regarding its judicious use cannot therefore, be, of aught but value to the profession.

SOME CRITICAL REMARKS ON SJOQVIST'S METHOD OF DETERMINING HYDROCHLORIC ACID IN THE GASTRIC JUICE.

Dr. Dmochowski, in verifying the Sjöqvist method of determining the amount of hydrochloric acid in the gastric juice, became convinced that in the application of this method, regarded from a chemical point of view, errors are possible, and that it does not therefore, answer the purpose to which Wagner had already directed attention. According to the author, the inaccuracy of this method is due to: (1) that baryta chlorate, when heated, decomposes into hydrochloric acid, which volatilizes, and oxide of baryta; (2) that the oxide of baryta thus formed combines with carbonic acid; (3) that the resultant carbonate of baryta, added abundantly to the gastric juice, also decomposes, forming baryta hydrate. The first two conditions impair the analytical results in one direction, and the third in another.—*Gazeta Lekarska*, August 10, 1891.

Book Reviews.

CEREBRAL MENINGITIS: Its History, Diagnosis, Prognosis and Treatment. By Martin W. Barr, M. D., Resident Physician in Pennsylvania Training School for Feeble-minded Children, etc. Detroit, Mich: Geo. S. Davis.

Another volume of the Physician's Leisure Hour Series is before us in the shape of a monograph upon cerebral meningitis in all its medical aspects. The author has endeavored to compile a treatise containing in as little space as possible the various forms of meningitis, together with the general history of the disease and its treatment.

In beginning the subject and in defining the meaning of the term meningitis, the author states that the arachnoid is never the seat of inflammation. This is contrary to a wide-spread belief, and we think that the statement should have been somewhat qualified. All admit the secondary involvement of the arachnoid by extension from the pia mater, and a large number of the most experienced clinical observers still believe in the possibility of acute arachnitis. If such cases do occur they are excessively rare, and as far as practical purposes are concerned the arachnoid may be wholly disregarded in the consideration of cerebral meningitis. For the sake of scientific accuracy it is, however, well to admit the occasional occurrence of simple arachnitis, because cases have been published which seem to prove conclusively that it can occur.

The classification adopted is simple and sufficiently expressive. Pachymeningitis is divided into external, internal and hæmorrhagic; the first being acute and the last two chronic affections. Simple meningitis is divided simply into acute, subacute and chronic; and further subdivided with reference to its situation into basilar, diffused, verticular and meningo cerebritis. Tubercular meningitis is classified according to its location only.

The author's observations of the disease in question were mainly confined to about fifty cases of meningitis occurring chiefly in mentally defective children, who are peculiarly liable to this affection. He has thus had a rich opportunity for study. The most remarkable statement is that concerning the brilliant results of the

treatment of these cases; thirteen out of the total number of fifty-one having recovered. This is an exceptionally good percentage of recoveries, especially when we consider the type of cases with which the author had to deal. His treatment consisted in using the iodide and bromide of potassium freely after the febrile stage of the disease. In the beginning he controls fever by drop doses of tincture of aconite and tincture of belladonna, well diluted with water. If necessary antifebrin is employed in three-grain doses. If stimulants are indicated by the condition of the pulse they are cautiously given. Calomel is administered to move the bowels. The diet is exclusively milk. Antipyrin and cocaine are used to prevent severe vomiting.

In conclusion, we may say that the book contains much valuable information. The opinions of the most prominent authorities are freely quoted, and the author has evidently taken particular care to present the subject impartially. He has not hesitated, however, to give his personal views, which materially add to its interest when we consider the excellent results in the treatment of his cases. The chapter on hæmorrhagic pachymeningitis is well-written. The author might, however, have noted the excellent observations of Dercum and other Americans regarding the ætiology of the affection.

LAVAGE IN CHRONIC GASTRIC DISEASE.

Dr. D. H. Attfield (*Practitioner*) states that the results of gastric lavage are eminently satisfactory. Vomiting is entirely checked as a rule after at most two or three repetitions. By use of the tube as soon as early symptoms appear the patient is saved hours of debility, nausea and pain; the precursors of acute vomiting. Decrease of pain resultant on vomiting occurs as a consequence, either of the removal of the reflex contraction of the stomach on slimy fermenting contents or as a result of removal of gastric irritation by washing out irritants. Appetite is invariably increased. The stomach tendency to dilatation is checked and removed, thus breaking up a vicious circle of debility producing gastric irritation and resultant gastric irritation increasing debility.

Correspondence.

DR. PHELPS MISQUOTES DR. SAYRE.

To the Editor of The Medical and Surgical Reporter:—My attention has just been called for the first time, to an article in your journal, of July 9th, 1892, by Dr. A. M. Phelps, which contains a misstatement, of so gross a nature, that I must contradict it.

On page 49, of your Journal of that date, Dr. Phelps says, "If you consult Dr. Sayre's book on 'Orthopedic Surgery,' you will find a case of hip joint disease reported, in which a child was kept in a wire cuirass for a few months, and the child not only came out with anchylosis of the opposite hip, but of the joints of the opposite extremity, and of the entire spine, and this was attributed to the immobilization; *yet strange to say, the side in which the disease existed, recovered without anchylosis.*"

The italics are mine. I will now quote the case Dr. Phelps refers to, as published in the second edition of my Orthopedic Surgery, pages 18 and 19, showing the inaccuracy of Dr. Phelps' statement.

"The case is worthy of recital. It was one in which there was fully developed disease of the hip joint. The lad lived at a long distance from the city, and the gentleman who performed the operation of tenotomy, did it in a skillful manner.

The limbs were dressed in the ordinary wire breeches, and the physician who had the case in charge, was instructed with the greatest care concerning the necessity of frequently removing the dressing, performing slight manipulations and then replacing it. The case had been for three or four years, one in which the patient had suffered the most intense agony, and had slept only under the influence of large doses of anodynes. As soon, however, as the patient was placed in the immovable apparatus, and properly extended, he was so perfectly comfortable and easy, and slept so well at night, that the doctor who had him in charge, thought it unnecessary to remove it, fearing he might not be able to replace it, and make him as comfortable as he then was, and had been since the apparatus had been applied. He was, therefore, permitted to remain in the wire

breeches for nine months, simply because he was so free from pain. The result was that the disease was cured; but Nature, had unfortunately cured it by *anchylosing not only the hip joint, which had been the seat of disease*, but the hip joint upon the opposite side, as well as both knee joints and both ankle joints." This sentence is not italicised in my book.

Comment on these two paragraphs is unnecessary, but Dr. Phelps' misquotation, places me in so false a light, before the profession, that I hope you will give this letter early insertion in your valuable journal, and oblige

Yours truly,
LOUIS A. SAYRE.

August 10th, 1892.

Periscope.

THERAPEUTICS.

THE USE OF VASELINE.

Dr. Novotny warns against the use of vaseline as a lubricator for sounds and other instruments introduced into the bladder, as he has twice found this insoluble vaseline serving as a nidus about which a mass of detritus had collected, and giving opportunity for the deposit of urinary sediment. In one case the quantity of ditritus thus massed together upon a quantity of vaseline weighed ten grammes.—*Memorabilien.*

A FATAL CASE OF BROMIDE OF ETHYL NARCOSIS.

From Prof. Billroth's clinic comes a warning which is reported by Dr. Alfred Gleich, in the *Wiener klinische Wochenschift*, 1892, No. 11, S. 167. Having successfully employed this anæsthetic in nearly four hundred instances, he records a fatal issue after the use of five drachms. The operation was multiple incision in a carbuncle in right deltoid region, and death resulted in three minutes from the commencement of the narcosis. the heart and respiration ceasing. The necropsy showed parenchymatous and fatty degeneration of the walls of both ventricles of the heart, as did the liver, and parenchymatous degeneration of the renal epithelium. —*Amer. Jour. Med. Sci.*

CRYSTALLIZED NITRATE OF ACONITE.

Lépine (*Sem. Mèd.*, March 30th, 1892) insists on the risks of prescribing crystallized nitrate of aconite in large doses: and points out that in the standard works on therapeutics the dose is stated to be 2, 3, and even 4 milligrammes a day, while in his experience it ought only to be given in doses of $\frac{1}{10}$ to $\frac{1}{8}$ of a milligramme, repeated every four—or, better every six—hours. In some cases is is necessary to give $\frac{1}{4}$ of a milligramme at the same intervals. He considers it necessary in every case not only to test the susceptibility of the patient, but also to know the degree of toxicity of the specimen of the drug that is being used, as this varies with the locality from which the aconite has been obtained for its preparation.—*Brit. Med. Jour.*

NOTES ON NEW ANTISEPTICS.

If we trace back the list of antiseptics and disinfectants to an early date we find that those mostly in use were sulphur, the halogen compounds, mercury, coal tar products and some essential oils. If we again follow up the development of antiseptics we find that these materials form the basis of most of our new antiseptics in a more defined and definite composition. Thus, in place of the old method of burning sulphur, sulphurous acid in many cases replaces it, and compounds of sulphur, as sulphonates, are used in combination, as in the case of ichthyol (ammonium-ichthyol sulphonate), soziodel (di-iodoparaphenol sulphonic acid), and many others. The same may be said of the halogens, iodoform, iodo and di-iodo-salicylic acids iodol being iodine derivatives, while the other elements forming this group have corresponding compounds in a greater or less variety.

The mercurial preparations are well known to us, the mercuro-zinc cyanide being one of the developments of chemistry with regard to antiseptics.

The coal tar products are both numerous and varied, and many varieties of new combinations are continually being found that promise to be of use as antiseptics.

Essential oils have been combined with other elements to form valuable antiseptics, aristol (dithy-moliodide) being one of

these, while oxidized pine oil with camphoric acid forms one of the most popular disinfectants of the present day.

Time does not allow me to formulate or describe the following preparations fully. I will therefore give such description as is necessary, with the hope that the members of the association will look into the matter for themselves for further information.

Among new antiseptics from coal tar derivatives may be mentioned pyoktanin, methyl-violet, the most antiseptic of the aniline colors. A solution of 1 in 1000 is used in various eye diseases, phthisis, ulcers, etc. There is a yellow variety commonly known as auramine, also used antiseptically.

Lysol is a saponified phenol derived from cresols, and contains the higher homologues of carbolic acid. It is said to possess higher antimycotic power than carbolic acid, and to be less poisonous. This preparation is much used in Germany at the present time.

Retinol, a distillation product of pine resin, is a viscid fluid hydrocarbon. It is a non-irritating and stable antiseptic.

Europhen, iso-butyl-ortho cresyl-iodide, contains 23 per cent. of iodine, and is non-poisonous.

Dermatol, a basic gallate of bismuth, forms a powerful antiseptic and dessicant.

Sulphaminol, thiooxydiphenylamine, the antiseptic action of which is due to its decomposition in contact with the fluids of the body into sulphur and phenol.

Monochlorphenol is prepared by the action of chlorine on cooled phenol. It is a powerful antiseptic and less irritating than trichlorophenol.

Camphoid, though only a mild antiseptic in itself, is a valuable adjunct to this class of bodies, as it forms a ready method of applying antiseptics to the surface of the skin, and owing to its composition (of spirit, camphor and hydroxylin) it forms a valuable solvent for substances such as salicylic acid, resorcin, hydro-naphthol and many others.—*S. A. Walton, in Pharmaceutical Journal.*

ANTINERVINE (SALICYLBROMANILIDE).

This substance is prepared by the interaction of salicylic acid, bromine, and acetanilide; it is a crystalline solid, insoluble in cold water, but soluble in hot water, alcohol, and ether, possessing a slightly acid but not disagreeable taste. It has been tried clinically by Bradford, of Philadelphia, Woodbury (*Med. Times and Register*, April 25th, 1891), and more recently by De Filippi (*Rif. Med.*, No. 201, 1891). While these differ as to the exact chemical constitution of the drug, they are are agreed as to its utility in a variety of conditions, and especially in cases of articular rheumatism and neuralgia. G. Laurenti (*Gazz. degli Oipitali*, March 17th, 1892) now gives his own personal experience with the drug, and comes to the following conclusions:—(1) It can be used with advantage in all forms of abnormal excitement of the nervous system, whether to subdue neuralgia or as a general nervous sedative (2) In rheumatism it may be used, and seems undoubtedly indicated as a drug comprising in itself antirheumatic, antipyretic, and analgesic properties. (3) Its low price and feeble toxicity, together with the evidence above given, render antinervine a useful addition to our list of remedies.—*Brit. Med. Jour.*

DIPHTHERITIC ANGINA AND ITS TREATMENT BY CRUDE PETROLEUM.

O. Larcher, Paris (*Bulletin de L'Academie Royale de Medicine Belgique*, February 27, 1892) recommends highly the use of crude petroleum in faucial diphtheria. Of forty-two cases in which he employed the remedy only two died. One of these were moribund when first seen, and in the other case the parents did not follow directions. Of the remaining forty cases one was sixty-five years old, one twenty-seven, one eighteen months and the rest between three and fifteen years. The treatment consists in gargles or applications or both alternately. In only two cases was the treatment restricted solely to the petroleum. But in all cases there was a rapid diminution of the false membranes, a separation of the edges and a profuse secretion which favored their separation. When thrown off they were immediately reproduced, but much thinner and smaller. The swelling of the glands diminished rapidly as the membranes decreased. Towards the end of the third day of the use of the petroleum an erythema appeared on the front of the neck and remained as long as the treatment continued. In only seven cases did paralysis

of the soft palate occur. He sums up his conclusions as follows:

(1) Crude petroleum alone is sufficient to ensure cure of faucial diphtheria. (2) Its use is free from all serious objection. (3) It does not interfere with the use of the other remedies.—*Univ. Med. Mag.*

GLYCERIN IN HIGH DOSES.

Catillion, at a recent meeting, remarked (*Med. Abstr.*) that while it is true that glycerin is a triatomic alcohol, it has none of the physiological effects analogous with those of alcohol even when given in doses as high as 40 oz. Constantin Paul, in contradiction, stated that he had met with the case of a man who was accustomed to take three ounces of glycerin daily; he presented so much cerebral excitement that it was necessary to confine him to an asylum for a considerable time. He did not use any wine or other alcoholic liquid.

TREATMENT OF TENIA WITH THE SALTS OF STRONTIUM.

M. Laborde (*Revue de Therapeutique Medico-Chirurgicale*, May 1, 1892) gives his treatment of tenia with salts of strontium. He uses lactate of strontium 20, glycerin q. s., water 120; giving f℥ss every morning for five days. He claims that it is nearly always successful.

PIPERAZIN.

C. Mordhorst has employed piperazin in doses of one to two grammes (fifteen to thirty grains) daily, in five cases of gout. He has found that piperazin has but little effect in lessening the acidity of the urine, but causes a marked diminution in the amount of crystalline urates; he has never been able to cause their entire disappearance by the use of this remedy. Piperazin does not, therefore, possess more energetic powers than the ordinary alkaline waters (Ems, Vichy, Carlsbad), and is rather inferior to the waters of Wiesbaden. Nevertheless, it must be remembered that piperazin is never followed by any secondary untoward effects, and that under its influence diuresis is markedly increased. Piperazin may, therefore, be used in all cases of gout with perfect safety. The most efficient treatment of gout is by the use of the waters of Wiesbaden; it neutralizes the acidity of the urine (which sometimes is neutral or alkaline without losing its limpidity), and often causes the total disappearance of the crystalline urates.—*Les Nouveaux Remèdes*, May 8, 1892, p. 205.

MEDICINE

IODIC PURPURA.

A case of generalized purpura over the trunk and the four extremities, from the ingestion of 1 gramme of iodide of sodium, is reported by Prof. Lemoine (*La Médecine Moderne, No. 52. Rev. Inter. de Bibliog. Mèd.*, April 25, 1892). This case differed from others previously related in that the eruption was quite confluent, forming arborizations and streaks over the skin; in its generalization, and in the intense itching that was produced. The purpura appeared twice under the influence of the sodic iodide, and at an interval of 15 days. The eruptive patches came on a few days after the administration of the drug and lasted for about a week. The patient had congestion of the kidneys and liver, and had previously suffered from albuminuria and jaundice. These latter organs could not perform their excretory functions, and it is probable, according to the author, that the iodide of sodium had to be eliminated by the skin and thus the eruption was produced. It would be interesting to examine, in cases of eruption caused by drugs, the state of the liver and kidneys, as it is probable that lesions of these organs may play an important part in the pathogenesis of said eruptions.

THE PATHOGENESIS OF BERI-BERI.

After describing some of the geographical peculiarities of South America, and the frequency of beri-beri and yellow fever in the north of Brazil, Leopold (*Joun. des connaiss. medic.—Berl. Klin. Woch.—La Médecine Moderne*, May 12, 1892) calls attention to the fact that there exist two forms of beri-beri. One of those forms is characterized by a general œdema and cardiac dilatation; the other form, by paralytic phenomena. The author, then, refers to the experience of Muzzo and Morelli performed in the Laboratory of Bacteriology

of Montevideo. In cultures made of the blood of animals suffering from beri-beri, four different specimens of micro-organisms were found, one of them being a micrococcus. This blood charged with such organisms, injected into that of healthy animals, produced a general degenerative neuritis; intra-meningeal injections of the same fluid produced the same phenomena. Sub-cutaneous injections practised in thirty animals caused the production of the œdematous form of the disease, accompanied with dilatation of the heart. Colonies of micrococci were found in the pericardium and the endocardium, and the changes observed in the muscles were characterized by a destruction of the muscular substance, the sarcolemma appearing, in the majority of cases, as an empty sac. The multiple neuritis described by Baetz and Scheube was noticed in all cases, that is, there was a total disappearance of the axis cylinder, accompanied with rupture of the myeline and a round-cell infiltration into the membrane of Schwan. There were, at the same time, a regenerative and a degenerative process. It was the peripheral nervous system that was particularly affected, but in the advanced cases the lesion extended itself to the posterior columns of the spinal cord, giving rise to the production of symptoms analagous to those of locomotor ataxia. In the majority of cases, nevertheless, the cord remained intact, and it was only in the advanced cases that the anterior horns became also implicated.

PLEURISY CAUSED BY THE BACILLUS OF TYPHOID FEVER.

In a note presented to the Academie de Mèdecine of Paris; Kelsch (*Rev. Inter. de Bibliog. Med.*, April25,1892) reported the following case: A man, 22 years of age, suffering from pleurisy of the left side, was admitted to the hospital. In the liquid extracted by thoracentesis (the pleurisy was hæmorrhagic) there was a bacillus resembling that of typhoid fever. The liquid, by inoculation, produced in guinea-pigs a pleurisy analogous to that from which the patient was suffering. Later, the effusion became purulent but it only contained then the bacilli of Eberth. The patient died tuberculous. At the autopsy not a single lesion peculiar to typhoid fever was found.

DISTINCTIONS BETWEEN THE BACILLUS OF TYPHOID FEVER AND THE BACILLUS COLI COMMUNIS.

At a meeting of the Société de Biologie, Dubief (*La Médecine Moderne*, No. 42, 1891, p. 745) reported that in making comparative experiments with the bacillus of typoid fever and the bacillus coli communis, he found that both organisms caused the fermentation of glucose in about equal degree, the colon-bacillus, however, giving rise to the formation of a large percentage of lactic acid. In consequence of this difference, the typhoid-bacillus but slowly causes the coagulation of milk, while the colon-bacillus produces the same result more speedily.

Before the Académie de Médecine, Roux and Rondet (*La Médecine Moderne*, 1891, No. 43, p. 741) maintained the identity of the bacillus coli communis and the bacillus of typhoid fever. The apparent differences that exist are considered as dependent upon the varying conditions to which the organism may be exposed.

A METHOD OF INCREASING THE INTENSITY OF HEART SOUNDS.

Azouley (*Gaz. des Hôp.*, May 12, 1892) communicated to the Academy of Medicine of Paris, May 10th, 1892, a method of procedure which allows of the more easy detection of cardiac *bruits*, when they are only slightly marked, and which is capable of bringing them into evidence when they are absent during our examination of the patient. It consists in making the patient lie as horizontally as possibly, with the arms raised above the head, and the head and legs raised as much as possible on cushions. Cardiac tension is thus increased, and the physical signs accentuated.—*Brit. Med. Jour.*

MENINGITIS CEREBROSPINALIS.

Dr. Oebeke reports the cases of two brothers who rapidly succumbed to a purulent meningitis. A bacteriological examination of the cerebrospinal fluid showed, in both cases, the presence of chain-cocci, which were cultivated upon agar-agar, but did not grow into a second generation. These cases are published to show that the disease is not a "masked" pneumonia as has been claimed, but is an independent disease.—*Berlin Klin. Wochensch.*, No. 41.

AVULSION OF THE STAPES IN ANIMALS.

Botey (*Ann. des mal. de l'oreille et du larynx,* xvii, 1), draws the following conclusions from his experiments: 1. The avulsion of the stapes in animals is an entirely innocuous operation. 2. Whether the oval and round membranes are torn or not, and whether labyrinthine fluid flows out or not, a new membrane, much thicker, is always formed after this operation. 3. In all cases, after the removal of the stapes, the animals hear well, but at a shorter distance than before. 4. In animals which have neither membrane nor columella, hearing is a little better than in those in whom the drum-membrane has been removed, while the stapes is left in place. 5. This operation would probably be equally innocuous in man, if it were possible to execute it equally well and under strict antiseptic precautions. 6. The drum-membrane and ossicula are not indispensable to hearing, but they simply re-enforce the intensity of sound-waves.

MOVABLE KIDNEY AND HYDRONEPHROSIS.

Lucas (*British Medical Journal*, No. 1617, p. 1343) maintains that movable kidney is a condition that, during displacement, may, and often does, lead to hydronephrosis and subsequent destruction of the liver, in consequence of twisting of the pedicle, or pressure of the organ upon the ureter. To avoid this danger, and to relieve the patient of pain, he recommends nephrorhaphy. Even when hydronephosis has become pronounced, relief may be afforded by nephrorrhaphy, and further degenerative change prevented. Three cases are reported, in two of which nephrorrhaphy was performed; in one, nephrecotomy was performed; in one, operation was declined.

EPILEPTIFORM ATTACKS FROM TÆNIA.

Martha has gathered twenty-two observations where epileptiform attacks could undoubtedly be traced to the presence of tænia. According to him the attacks are not much different from those of classic epilepsy. Expulsion of the parasite causes a cessation of the spasms; yet the attack has not the characteristic brusqueness of true epilepsy. The patient finds time to throw himself upon a bed, or to call for help, while grave injuries and falls are exceptional. The initial cry, biting of the tongue, and frothing of the mouth are inconstant signs and of no great diagnostic importance. The convulsive and comatose periods are of longer duration than in true epilepsy; the attacks have a tendency to become periodic. The male sex is more frequently attacked than the female. Nervous hereditary or personal antecedents have no important influence. Unilateral movements are not regularly observed as in true epilepsy.—*Arch. Général de Méd.*, Nov. and Dec., 1891.

IODOFORM DERMATITIS.

A well marked case of this affection is recorded by Legiehn. The patient was a man suffering from purulent catarrh of the right middle ear, for which syringing with warm water and insufflations of iodoform were prescribed. The discharge, which had lasted five weeks, ceased in three days, and the hearing power considerably improved. In order to be on the safe side the patient continued to use the iodoform, until on evening he experienced immediately after an insufflation a feeling of warmth in the ear, and in the morning found to his astonishment his face swollen. The right ear and right half of the face and neck were reddened, much swollen, and œdematous; and the cheek was covered with eczematous bullæ. There was moderate itching and marked feeling of heat complained of in the inflamed parts; and there being a possibility that the iodoform had something to do with it, the powder was discontinued, and ichthyol ointment used, under which the eczema rapidly healed. Two weeks after, the patient noticed a return of the otorrhœa, and although convinced that the insufflation of iodoform was the cause of the previous swelling of the face, he again employed it, hoping to receive marked improvement of the discharge. About an hour after, he perceived a hot sensation in the outer ear; and in the course of the night, the ear and face had assumed the same appearance as before. The former treatment sufficed to make it disappear as rapidly as before. Leghiehn thinks there cannot be the least doubt that the dermatitis depended upon the iodoform, as on the first examination there was nothing in

the ear passage that could possibly cause it, and its recurrence on the second occasion confirmed this fully.—*Therap. Monatshefte*, No. 4, 1892.

HERPES ZOSTER.

V. Valdettaro, in a graduation thesis (Genoa, 1892) relates experiments which show the accuracy of inferences previously made by clinicians regarding the existence of a simple and septic form of herpes. In the simple form the fluid from the vesicles contained no organism which produced symptoms in animals. When inoculated in gelatine the results were negative. In the other variety, in which the vesicles contained a whitish, thick, purulent discharge, the organisms, which grew in white transparent colonies in agar-agar, produced septic symptoms when inoculated into the cornea of animals. The author regards the sepsis as essentially distinct from zoster, with which it is present as a complication.—*Brit. Med. Jour.*

ON THE CAUSE OF COMPLICATIONS AND EARLY DEATH AFTER SEVERE BURNS.

Silbermann (*Virchow's Archiv*, Bd. cxix, p. 488) gives the following summary of observations:—

1. After severe burns not only is there an alteration in the shape of the red blood corpuscles, but there is also diminution of their vital properties, shown by their changed reaction to dessication, heat, compression, salt solution, staining, etc.

2. These changes and the presence of numerous broken up corpuscles result in the formation of numerous thrombi, occluding vessels, and causing stasis in various internal organs especially in the lungs, kidneys, intestine, liver, brain, and subcutaneous cellular tissue.

3. These points of occlusion of vessels, which are most numerous and striking in the branches of the pulmonary artery, are formed during life.

4. There results therefore considerable obstacle to the emptying of the right ventricle, with consequent general venous stasis and corresponding arterial anæma.

5. These conditions (general venous stasis and arterial anæmia, and local points of thrombosis and stasis) produce hæmorrhages, ulceration, and parenchymatous changes in various organs.

6. Thus may be explained, as occurring after severe burns, dyspnœa, cyanosis, coma, smallness of pulse, various lung affections, convulsions, anuria, and lowering of the body temperature.

7. The fatal result from comparatively limited burns in children may be due to (1) the more intense action of heat upon the corpuscles owing to their thinner skin; (2) the weaker resisting-power of their corpuscles; and (3) the comparative weakness of their heart and circulation generally.—*Centralbl. f. Chir.*, May 30th, 1892.

THE GONOCOCCUS IN PURE CULTURE.

Gebhard (*Berl. Klin, Woch.*, 14th March, 1892). The artificial cultivation of the microbe of gonorrhœa has hitherto been regarded as one of the most difficult tasks in practical bacteriology. The method published by Bumm in 1885 was of such a nature that few were able to obtain his results. An important advance was made by Wertheim in 1891, in that he showed the possibility of obtaining pure cultures from gonorrhœal pus by the plate method. Gebhard has made cultures successfully from eight cases (one of them being a case of ophthalmia neonatorum). He used, with some modifications, the nutritive medium prescribed by Wertheim —namely, a mixture of equal parts of human blood serum (obtained from retroplacental blood) and agar-jelly (Fleischinfuspeptonagar). The plates are kept at the body temperature, and at the end of twenty-four hours very small whitish-yellow colonies are distinguishable amongst other kinds. These continue to grow for a week or two, assuming about the third day a characteristic microscopical appearance. Each one appears, when magnified about fifteen times, as a sharply bounded irregular mass, with a finger-like projection from the centre. The individuals of such a colony are seen as irregular hemispheres varying in size, frequently arranged in fours, and staining readily with the aniline dyes, but not by Gram's method. The coccus here described cannot grow on the ordinary nutritive media, and thrives but poorly on blood serum alone. Inoculated on the mucous membrane of the human urethra, it produced a purulent catarrh, running the clinical course of gonorrhœa, and showing in the catarrhal products gonococci.

TRAUMATIC PORENCEPHALY.

The patient was 11 months old when he came under observation. He then showed a swelling over the right parietal bone which had developed five weeks before. Three exploratory punctures showed a bloody serum. The swelling showed distinct pulsation, and measured 9.5 by 7.8 cm. A distinct fissure in the bone could be felt. A diagnosis of meningocele spuri traumatica was made. Somnolence developed and operation determined on. A sagittal incision discharged a quantity of yellow serum. A fusiform fissure 10 cm. long and 1 cm. wide at its widest part was found running from above and behind, downward and forward. Two holes as large as peas were found in the dura. There was a very free discharge of serum and the wound was five months in healing. At this time it was seen that the fissue in the bone had enlarged, an oval space 3 by 2.5 cm. being present with everted edges. The soft parts covering this were bulging. Slight spasm of the left angle of mouth and left eyelid occurred frequently. Death from pneumonia 8 months after operation. Autopsy showed a fissue in the brain corresponding to the fissure in in the bone. The posterior cornu of the lateral ventricle extended to the dura in this locality.—*Prof. Weinlechner and Dr. Kolisko, Prog. Med. Wochensch., No. 33, 1891.*

HEMIANOPSIA WITH HALLUCINATIONS ON THE BLANK AREA OF THE VISUAL FIELD.

Dr. H. Bidon gives some curious details of a case of hemianopsia which he had recently observed. The patient was a soldier, æt. 59, who had had no serious illness, but had fallen into habits of spirit drinking. On February 20, 1891, he had a slight apoplectic attack, with loss of consciousness for two hours. When he came to himself he complained of a headache and something the matter with his eyes. His speech was slow, but there was no aphasia, and no paralysis of any part of him. He kept on drawing attention to his eyes and complaining vaguely that he was going blind. This led to a careful examination of them, and it was easy to establish that there was a complete left lateral homonymous hemianopsia, of which there had been no sign before his apoplectic attack. The left half of the visual field in each eye was completely blank, the right slightly contracted. But the most curious point was that in the blank visual area, and in that alone, there were frequent hallucinatory appearances of all sorts: figures in strange dresses, shadowy forms and confused scenes of every description, which for the first few days puzzled and distressed him. To these, however, he grew accustomed after ten days or so, and by the end of six weeks they had completely disappeared, although the hemianopsia remained undiminished and unaltered. At the end of another six months the hemianopsia still persisted, but there had been no return of the hallucinations, and no fresh cerebral injury. The symptoms were few but distinct, and pointed to a small lesion in the right occipital lobe. That it was cortical was probable from the abscence of all other motor and sensory consequences; that it was a thrombosis rather than a hæmorrhage was more probable if its position was cortical. That what inhibited the functions of a limited area should excite its neighborhood was not unlikely; and Tamburini has shown that the excitation of some cortical centres may produce visual hallucinations, though this combination of excitant and inhibitory effects in such a limited area is both rare and interesting.—*Revue de Méd.,* p. 1014, December, 1891.

HISTOLOGICAL EXAMINATION OF THE MIDDLE AND INTERNAL EAR IN A CASE OF DEAF-MUTISM.

Dr. Arno Scheibe, of Munich, examined the two temporal bones in a case of deaf-mutism, and the results, as translated by Dr. Spalding, form an interesting contribution in the *Archives of Otology.*

Shortly, the middle ear was found to be normal apart from some thickening of its lining mucous membrane, and partial degeneration of the tensor tympani muscle. In the labyrinth there was atrophy of the nerves of the cochlea, sacculus, and posterior ampulla, as well as alterations in the membranous structure of the cochlea and sacculus. This atrophy was confined to the nerves in those three parts—that is, to those three branches which, before their entrance into the petrous bone, compose the posterior ramus; while the nerves of the utriculus and the other two ampullæ

which compose the other trunk of the auditory nerve—the anterior branch—were only slightly affected.

There was no trace of any former inflammation in the labyrinth, which is usually the case when deaf-mutism is associated with atrophy of the auditory nerves.

A description of the microscopic appearances in the various parts is fully given in the *Archives of Otology*, January, 1892.

SURGERY.

SURGICAL TREATMENT OF GRANULAR CONJUNCTIVITIS.

According to Darier(*Arch. D'Opthalmologie*, p. 95, 1892) granular conjunctivitis is evidently an affection of microbian origin, and its definite cure, as in other diseases of the same nature, like lupus for example, cannot be obtained except by complete destruction of the infectious tissue. The classical treatment is, therefore, in rebellious cases, substituted by the surgical treatment. This treatment as practiced in the Clinic of Dr. Abadie, consists in the scarifying, *rubbing* and scraping of the granulations, under chloroformization, and afterwards in completely exposing the eye-lids by reversion. After this manœuvre, washings with a solution of corrosive sublimate, of the strength of 1 to 500, must be made use of. On the following days, these lotions are renewed and the work of reparation carefully watched. In case of relapses, the *rubbing* is re-applied. The cure is obtained in about fifteen days or a month, at most. In 130 cases granular lids thus treated, not a single absolute failure was recorded; seven patients were operated twice, and one three times. No symblepharon was ever observed. The complications of the cornea are quite rare and always of little importance.

ANTISEPSIS IN OPHTHALMOLOGY.

According to A. C. Dismissas (*Rec. D'Ophthalmol.*, p. 129), 1892, the antisepsis of the instruments and of the operating field is not sufficient to obtain the results desired in the practice of surgical ophthalmology. "Our knowledge," he adds, "of the phenomena of auto-intoxication and auto-infection, ought to remind us of our duty in endeavoring to prepare the organism by a general treatment adequate to every case, and to practice also as rigorous an internal antisepsis as possible; for instance, calomel in purgative doses five days before the operation, the administration on the the following days of salol, salicylate of magnesium and bicarbonate of sodium; finally, general baths, alcoholic frictions, and the use of light diet: milk, eggs, vegetables. Care must also be taken regarding the causes of infection, originating in neighboring parts, the prevention of which can be brought about only by the application of the most rigorous measures. The antisepsis of the lachrymal ducts is of the greatest importance. Warm injections of a solution of the bichloride of mercury, made twice a day, is sufficient in the majority of cases. It is similarly important to disinfect for several days, the nasal and the naso-pharyngeal cavities and the Eustachian tube, by means of douches, injections or insufflations with antiseptic powders. The asepsis of the operating field may be obtained by the daily application of solutions of the bichloride of mercury of the strength of 1 to 4000. In regard to the instruments, these may be rendered sufficiently aseptic by boiling water after they have been placed in absolute alcohol. After the operation it must not be considered sufficient to wash out the field of operation with solutions of corrosive sublimate; it is absolutely necessary to apply antiseptic padding, this being renewed not later than the fourth day." The author terminates his work by recommending, after the operation, the constant application of antiseptic precautions and hygienic measures, as even a late auto-infection may be feared.

COMPRESS LEFT BEHIND AFTER ABDOMINAL SECTION AND PASSED AT STOOL.

Pilate, of Orleans (*Union Méd.*, March 31st, 1892) in April 1890, removed a painful fibroma from a woman, aged 42. In order to protect the viscera, he used sponges and also tarlatan antisepticised compresses. On the evening after operation there was vomiting, then pains in the right flank came on. Phlebitis of the right leg set in. These symptoms soon disappeared, and the patient recovered completely. Six months later pains in the region of the liver occurred; they

were taken for hepatic colic. The pains became diffused over the abdomen, and vomiting and tympanities without fever occurred. At length a rise of temperature set in, and swelling around the uterus was detected. The patient became weak and thin, and an operation was about to be performed when she passed the compress in a mass of hard fæces. The patient at once recovered. Quenu related a case where a compress was left in on account of the confusion caused by the patient threatening to sink under chloroform during operation. The patient died, and the compress was found rolled up in a coil of intestine. Terrillon observed a case where pressure forceps remained eight months in the abdomen, and came out close to the umbilicus.—*Brit. Med. Jour.*

EPICYSTOMY.

Prcf. Weinlechner showed a 74 year patient who suffered from calculi in viscus for 30 years. In 1880 Dummreicher undertook the operation of epicystomy owing to great enlargement of the prostate. Two stones weighing twenty-six grams, urate in character, were successfully removed. Perfect healing took place in three weeks. The operator then remarked over the advantages of the operation for the bladder healing. The patient now returns, complaining of the stream intermitting, as if stone were present. No calculi are present but the assumption is that the trabecular sheath of the viscus falls up against the inlet of the catheter and checks the flow.

A BLOW UPON THE EAR FOLLOWED BY DEATH IN A WEEK.

Heiman (*Arch. of Otol.*, xx, 1) reports the following interesting case: A soldier, aged twenty-one, had been struck on the left side of his face and ear, which caused severe vertigo. The blow caused severe hæmorrhage from the ear, which, however, came on forty hours after the blow. The ear had previously at times discharged pus. The patient died delirious on the seventh day after the injury. The autopsy showed pachymeningitis interna purulenta diffusa, numerous small subarachnoid hæmorrhage, hyperæmia of the substance of the brain and its membranes, and circumscribed basilar meningitis. A decolorized thrombus was found in the superior longitudinal sinus, and dark-thrombi were found in the transverse sinus and internal jugular vein. Three small openings were found on the inner surface of the pyramid which led to the tympanum. The upper surface of the mastoid was found sclerosed, and here there were several small softened areas containing pus and particles of bone. The tympanum and mastoid process were filled with thickened pus. In the mastoid were several large cavities containing pus. Pseudo-membranous bands were found in the middle ear, and the mucous membrane was ulcerated. There was a small perforation in the anterior part of the drum-head.

FRACTURES OF THE SKULL.

Dr. John Ashhurst's rule is, that in depressed fractures, if the fracture is impacked, there is no occasion for trephining as a primary operation. If the bones are not separated there will be no entrance of air to the parts below. If the parts are not exposed to the air the results are apt to be more favorable. When the depression, therefore, is not so great as to cause separation of the fragments, do not interfere. The old rule, that the surgeon should trephine in all cases of compound fracture, the lecturer considers not good. If there are convulsions then the trephine should be used.—*Internat'l Clinics*, Jan., 1892.

TREATMENT OF SYPHILITIC STRICTURE OF THE RECTUM BY EXTIRPATION.

Quénn (*Bul. et Mem. de la Soc. de Chir. de Paris*, vol. xvii., p. 140.) states that the results of the old treatment of syphilitic stricture of the rectum by dilatation by means of bougies or by rectotomy have always been unsatisfactory. Nor could extirpation of the rectum, though repeatedly recommended and performed in Germany, thoroughly satisfy the surgeon as long as the patients were condemned to permanent incontinence. Kraske's method of preserving the sphincters in the treatment of rectal ulceration and stricture was a decided step in advance. For lower stricture without extensive ulceration above, resection of the coccyx and sacrum is unnecessary, incision of the soft parts being sufficient.

OBSTETRICS

DISEASE OF UMBILICUS IN NEWBORN CHILDREN.

Eröss, of Buda-Pesth (*Archiv f. Gynäk.*, vol. xii, part iii, p. 407) gives the results of his observations of 1,000 newborn infants. He paid special attention in each case to the mummification and fall of the stump of the cord under different modes of treatment. He finds that ideal cicatrization of the umbilicus with no local or general morbid changes is not the rule after birth. It was observed in 320, or 32 per cent, of the cases. In 680, or 68 per cent., distinct, severe, or even fatal morbid processes had their origin in the umbilicus. These processes were sloughing of the stump of the cord (147 cases); softening instead of perfect mummification of the stump (182); decomposition of fragments of stump overlooked after the rest had fallen (224); suppuration of the navel (109); ulceration of navel (17): and gangrene of navel (2). (The figures, as given by the author, make a total of 681 morbid cases, although "320" is given as the number of cases of "normal cicatrization" in the same table). Out of the 680 abnormal cases, fever was observed in 220. It disappeared before discharge from hospital in 158 of the infants. Fever, Eröss concludes, is a very precise evidence —often the sole indication for some time— of infection of the infant's system through disease of the umbilicus. As the infants remained but from eight to ten days in the institution where these researches were made, no precise conclusions as to the course and mortality of the fever could be obtained.—*Brit. Med. Jour.*

BELLADONNA IN THE FIRST STAGES OF LABOR.

Dr. Asher, in the *Australian Medical Journal*, says that in all cases in which, in spite of persistent pains, the mouth of the womb fails to dilate sufficiently (especially with primaparæ,) he is in the habit of giving from 20 to 30 drops of tincture of belladonna every hour, or even more frequently. Less than 20 drops will not answer. In every one of numerous cases cited there was energetic and rapid dilatation of the col, diminution of suffering, and a happy delivery. He considers belladonna in every way superior to chloral.

HÆMORRHAGE AT COMMENCEMENT OF PREGNANCY.

Mijnlieff, of Brenklen (*Nouv. Arch. d' Obstet. et de Gynec*, October, 1891), describes a case where a 3-para had an attack of flooding fifteen days after the suppression of the period. The loss was severe, but was stopped by the tampon. Hæmorrhages recurred and caused severe anæmia. The induction of abortion was advised but the patient refused to undergo the necessary steps for that purpose, owing to religious scruples. At length, the movements of the child were felt, and two months later, when the report was read, the fœtal heart sounds were audible. A sero-sanguinolent discharge was still present. Professor Treub reported a similar case, where he induced premature labor on account of the anæmic state of the patient. He discovered a malformation, uterus bipartitus. From one of the cornua a living fifth-month fœtus was removed, from the other an aborted ovum. Mijnlieff describes a case of hydramnios where twins were delivered; a great red mass with much liquor amnii was extracted after the second fœtus. It was a very large thrombus. The patient stated that she had been struck on the abdomen.—*Brit. Med. Jour.*

GYNECOLOGY.

PNEUMOCOCCI IN THE PUS FROM A PYOSALPINX.

Frommel (*Centralblatt für Gynäkologie*, 1892, No. 11) reports the following case: The patient, aged thirty-eight years, had a tuberculous disease of the left apex at the age of twenty-three, and later Pott's disease. She had aborted seven times. Laparotomy was performed for pyosalpinx on the right side; during the operation pus escaped into the cavity and the patient died of septic peritonitis on the third day. At the autopsy no old changes were found in the lungs. Bacteriological examination of the pus from the tube revealed the presence of microörganisms exactly resembling Fränkel's pneumococci, which retained their virulent properties in pure cultures, animals inoculated with them rapidly succumbing. Fränkel himself confirmed the diagnosis:

Aside from the interest attaching to the unusual presence of these cocci in a pyo-

salpinx, is their extreme virulence toward the peritoneum, although none were found in the cavity after death. Since the autopsy was not performed for forty-eight hours, it is quite probable that they were originally present and were destroyed post-mortem. How they entered the tube it is impossible to say. Neither in this case, nor in a similiar one reported by Zweifel, was any pneumonic process found in the lungs. They must have been in the air and found access to the genital tract through the vagina in the same manner as other ubiquitous organisms.—*Amer. Jour. Med. Sci.*

TREATMENT OF METRORRHAGIA.

In certain cases of obstinate metrorrhagia, ergotin, extractum hydrastis Canadensis, ice, and applications of tampons are alike incapable of arresting the hæmorrhage. In such cases a hypodermatic injection of sulphate of atropine has been recently recommended. It is given in doses of $\frac{1}{200}$ grain twice daily. In one case, in which the hæmorrhage had existed for a fortnight, it was completely arrested after the fourth injection. In a second, when the patient was in a state of collapse, the first injection was followed by a return of the normal temperature and increase of the pulse-rate; after the second the hæmorrage was diminished in a striking degree; after the third it entirely ceased. A moderate dilatation of the pupils was the only secondary effect observed.—*The Provincial Medical Journal*, May. 1892, p. 252.

COMPENSATORY HYPERTROPHY OF THE OVARY.

Dr. Airstoff, in his dissertation on the compensatory hypertrophy of the ovary, the materials for which he obtained from the pathological department of the St. Petersburg Medico-Chirurgical Academy, under Professor Ivanovski, states that, according to his observations, when one ovary has been removed the other one increases in size and weight, the follicles coming more rapidly also to maturity and withering more quickly, besides which the medullary layer increases. In observations made on rabbits it was found that the hypertrophic process had begun within two months after the operation, and that at three or four months it had nearly doubled the size of the remaining ovary. After the fifth month the remaining ovary became smaller again.—*The Lancet*, April 30, 1892, p. 991.

RETROFLEXION AND GASTRIC NEUROSES.

Panecki, of Danzic (*Der Frauenarzt*, May, 1892) is convinced that retroflexion of the uterus is in some cases the direct cause of several forms of gastric disturbances. He has closely examined fifteen cases where retroflexion existed in conjunction with dyspepsia, gastric catarrh, dilatation of the stomach, etc. In eight the gastric symptoms disappeared after satisfactory reposition of the uterus. In three no relation could be found between the uterine disease and some gastric neurosis. In four gastric disease was traced to some distinct local cause. When remedy of the retroflexion gives no relief from gastric symptoms, careful investigation is necessary to discover the true cause of the affection of the stomach.—*Brit. Med. Jour.*

PEDIATRICS.

THE USE OF HYPODERMATIC INJECTIONS IN CHILDREN.

In an excellent work, Legroux (*Jour. de Méd. et de Chir. Prat. Le Bulletin Médical*, April 22, 1892) gives the following *resumé* of the reasons favoring the employment of hypodermatic injections in children, notwithstanding the pain that such injections may and do produce: 1. The difficulty of administering the medicament on account of its bad taste, or the impossibility of giving it to children in the form of pills or *cachets*, as for example, the salts of quinine. 2, The great efficacy of absorption, as is found in regard to ergot and caffeine. 3. The rapidity of stimulation or of the analgesic effects produced upon the nervous system, as for instance, from the hypodermatic injections of ether, morphine, cocaine and antipyrine. 4. The changes that certain remedial agents undergo when introduced into the stomach, as for example, blood-serum of the dog. 5. The intolerance of the stomach to large doses of drugs like creasote. 6. The obstinacy of children, finally, in refusing to take all and every drug.

In the practice of the hypodermatic method, the greatest antiseptic precautions should be observed. The solutions used must be clear, the remedies pure, and the doses strictly accurate, in order to prevent the formation of local abscesses and the production of other deleterious effects. The hypodermatic injections of the following medicaments are indorsed by Legroux:

Chlorhydrate of quinine, in doses of 25 centigrammes, as in this formula:

℞ Chlorhydrate of quinine.....1 gramme
Distilled water.....4 grammes
M.—Each syringeful containes 25 centigrammes.

This injection has given excellent results in the treatment of pneumonias and broncho-pneumonias, and in that of intermittent and typhoid fevers of children. In order to obtain the best effects, the injection is to be repeated twice or thrice, according to the age of the patient.

Ergot, in the form of Yvon's solution, in doses of 1 gramme, or in that of Tanret's ergotine in doses of four or five drops, morning and evening. These injections have been of great service in cases of acute nephritis, accompanied with hæmaturia, in those of hæmaturia resulting as a sequela of scarlatinous nephritis. The injections are similarly indicated in cases of passive congestion of the lung; in those of slow-revolving pneumonias and broncho-pneumonias; and finally, in prolapse of the rectum, in nocturnal incontinence of urine, and in insufficient tonicity of the anal sphincter.

Neutral, pure ether, in doses of a half-syringeful, introduced deeply into the muscles, not under the skin, is useful in cases of slow-repairing gangrenous patches.

Caffeine in solution with benzoate of sodium, frequently employed in infectious diseases, is used in conditions of cardiac weakness or continuous adynamia, or when diuresis is desired. It may be given in doses of 25 centigrammes for each injection.

Antipyrine, in doses of 25 centigrammes, may be employed in cases of persisting vomiting or to produce a calming effect when pain is intense.

Creasote, in doses of from 2 to 6 cc., slowly injected, is well tolerated, produces little pain, and has been found quite useful in pulmonary tuberculosis. The injections of this drug have also given good results, as antiseptic and antithermic, in diphtheria. The results obtained in 68 patients suffering from this disorder, warrant the further employment of the drug.

HYGIENE.

ALKALI AND BACTERIA IN WATER.

M. Jean Rossi, in a thesis presented to the University of Geneva (1892), gives an account of experiments made with a view of ascertaining the influence of alkalinity on the number of colonies developing on gelatine plate cultivations of natural waters. The author very properly points out that numerical results are only strictly comparable when the plate cultures have been made with one and the same specimen of jelly. He broadly confirms the previous results of Reinsch, that the addition of sodium carbonate to the jelly in excess of that required to render the medium neutral leads to the development of a larger number of colonies, and he has also investigated the effect of adding other alkalies. The experiments may be thus summarized:

Additions to Beef Jelly.	Number of Colonies.			
	Carbonate of Soda.	Carbonate of Potash.	Caustic Soda.	Caustic Potash.
Per Cent.				
0. 0	72	72	72	72
0.05	133	60	30	73
0.10	73	67	0	25
0.15	62	53	0	0
0.20	55	47	0	0
0.50	39	6	0	0
1.50	0	0	0	0

It must not, however, be supposed that these figures have any absolute significance, depending, as they do, upon the particular forms of microbes which happened to be present in the waters experimented with. —*Brit. Med. Jour.*

THE DANGER OF CELLULOID BUTTONS.

Professor C. Vernon Boys of England, reports the case of a lady, standing near a bright fire, who suddenly found herself in smoke. A gentleman who came to her rescue succeeded in crushing the ignited portion of her dress, not, however, without severely burning his hands. On investigation the fire was found to have originated from a spot where a large fancy

button had been, but had disappeared. Similar buttons were subsequently examined, and were found to be highly inflammable, being made of celluloid.—*Annals Hygiene.*

MEDICAL CHEMISTRY.

A LABORATORY DEVICE.

Most practical chemists are painfully aware of the unsightly appearance of reagent bottles, caused by the drops of the solutions running down the outside and crystallizing thereon. This may be prevented by simply painting the rim with melted paraffin. Care should be taken to cover only the side of the lip—none should be put on the upper surface. This can be accomplished most easily by using a small hog-hair brush and a wax of low melting point, such as is used for embedding sections. It will be found that besides preventing the solution trickling down the outside, it enables one to deliver the reagent easily in single drops without resorting to the plan of one party withdrawing the stopper.—*Monthly Journal of Popular Science.*

A SIMPLIFIED METHOD OF MILK ANALYSIS.

E. Gottlieb recommends the following modification of B. Roese's method of milk analysis, which is expeditious and said to yield accurate results:

Into a cylinder of about 45 cm. high, and graduated in ½ cc., 10 gm. of milk are introduced. The weighing is done in a small flask, in which the adhering film of milk (after its being poured into the cylinder) is easily determined, since this film is practically uniform each time To the milk in the cylinder there are added, first, 1 cc. of 10-per-cent. ammonia (specific gravity 0.960), the mixture being shaken; next, 10 cc. of 95-per-cent. alcohol, the mixture again shaken; and finally 25 cc. of ether. The cylinder is now closed with a cork having a smooth, clean, and perfect face inside, and previously dampened with water so as not to absorb any of the liquid contained in the cylinder. On shaking the cylinder several times up and down the milk fat will readily dissolve in the ether. Next 15 cc. of petroleum benzine are added, the whole once more shaken, and the cylinder then set aside during at least six hours, so that the contents may separate in sharp layers, the upper one being a solution of the fat in the ether and benzine, the lower one a transparent, clear solution of casein and milk sugar, while the phosphates form a white sediment at the bottom. The volume of the upper layer is read off, and the largest portion of it transferred by a slender glass siphon into a small weighed flash. The ether and benzine are evaporated off at a gentle heat, the flash then heated during one or two hours in a drying oven at 100° C., cooled in a desiccator, and weighed.

The fat must be perfectly clear and free from the odor of benzine.

The weight of the fat found in the fraction of the ethereal solution siphoned off furnishes, by a simple calculation, the total amount of fat in the 10 gm. of milk. —*Landw. Versuchsst.*, vol. lx., 1.

NEWS AND MISCELLANY.

EXPERIMENTS ON LIVING ANIMALS.

The annual return of experiments on living animals, together with the report of the Inspector for the year 1891, has been presented to the House of Commons. This return, together with Dr. Poore's report, affords evidence that scientific researches in physiology, pathology, and pharmacology have been prosecuted with considerable earnestness during the past year. The total number of licensed places was 59, and of lincensees 153, while the total number of experiments was 2,661. Of these experiments, 986 were performed under the conditions of the license alone, or Certificate C, and were consequently painless, as the animal, under these conditions, is never allowed to recover from the anæsthetic, while 1,406 were merely inoculations or hypodermic injections, to which it is a misuse of terms to apply the word "vivisection." There thus remains only 269 experiment performed under the Certificate B, in which the animal, being anæsthetised during the operative procedure, is allowed to recover from the anæsthetic. In these cases the wounds are necessarily treated antiseptically, and everyone who has been under the surgeon's knife under similar conditions must know

that such wounds invariably heal without causing pain.

As regards the nature of the experiments, 784 were physiological, 1,457 were pathological, and 420 were therapeutical or pharmacological.

"The total number of experiments," continues Dr. Poore, "shows an increase upon last year. This is more than accounted for by the increased number of experiments under Certificate A, due to the demand for exact knowledge as to the mode of propagation, the prevention, and treatment of those diseases which are caused by living organisms. Under all the other certificates (except C) there has been a decrease in the number of experiments as compared with last year. Among the diseases, the causation of and the protection from which have occupied the attention of licensees during 1891, may be mentioned tubercle, cholera, cancer, erysipelas, diphtheria, influenza, rabies, glanders, distemper, 'black quarter,' 'black leg,' malignant œdema, swine fever, anthrax, necrosis of the liver in sheep, food poisoning, lead poisoning, goître, and cretinism. The physiological and therapeutical experiments have been of equal importance, and have included investigations on many of the most important functions of the body, and the mode of action of many drugs. During 1891 the licensees have, as usual, shown a most loyal regard for both the letter and the spirit of the Act. During the past year 131 visits of inspection have been made by Dr. Russell and myself, which have been severally reported with such details as was necessary."

Anyone not absolutely blinded by prejudice must admit that this report shows that the Vivisection Act is thoroughly fulfilling the object which Parliament had in view when it was passed. It was never intended to check experimental work, but merely to control it; and if the Act be worked fairly and liberally, it is conceivable that it may ensure a higher quality of work and greater thoroughness. The report at least affords evidence that the licensees are all of high scientific standing, and that all experiments are carried on in properly equipped laboratories. where the workers have the advice, and, if necessary, are subject to the control, of their seniors, and where there is every facility of making full and proper use of the labor expended on the work. The report also affords evidence that what the public is told with regard to the horrors of these experiments is mere exaggeration born of fanaticism.

The report can be bought of the Queen's printers for 3d., and we cordially recommend its perusal to all who are really anxious to get some insight into the merits of the question.—*Brit. Med. Jour.*

SUICIDE DURING PARTURITION.

Recently, a case occurred in Wigane England, where the woman, after some hours of labor, and upon the midwife telling her that it was necessary to have the aid of a medical man, owing to its breech presentation, while the husband went for the doctor, left the house, notwithstanding the protestations of the nurse, and when the doctor and husband returned she was nowhere to be found. The medical man waited some time while a search was made for her, and then left. Next morning her body was found in the canal with the newly-born infant. The shock produced by sudden immersion must have cause the uterus to expel its contents.—*Lancet.*

PREHISTORIC SYPHILIS,

The precise period of the world's history when syphilis became recognized as one of the diseases to which human flesh is heir has always been a matter of debate. But recent researches by Prokscy rather seem to indicate that the malady in question is of much earlier origin than has been generally supposed. This inquirer asserts that he had found in the papyri from the library of Sardanapalus, dating back seven hundred years B. C., proofs of the prevalence of syphilis among the Babylonians and Assyrians. In the legend of Idzdisher both his heroes were punished with a disease which affected the skin and generative organs. One of the heroes, after unnatural sexual connection, sickened and died. —*Med. Press.*

WM. R. WARNER & CO.

SEDATIVE. ANODYNE.

EFFERVESCENT
BROMO
(WARNER & CO.)
SODA.

Caffein 1 Grain, Bromide Soda 30 Grains in each heaping teaspoonful.

USEFUL IN

Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Sea-sickness, and Epilepsy.

Dose and Composition.—A heaping teaspoonful, containing Bromide Soda 30 grains, and Caffein 1 grain, in half a glass of water, to be repeated once after an interval of 30 minutes, if necessary.

ANTI-RHEUMATIC. SEDATIVE.

EFFERVESCENT.
BROMO
(WARNER & CO.)
LITHIA.

EACH DESSERTSPOONFUL CONTAINS:
℞ Salicylate Lith a 10 grains, and Bromide Soda 10 grains.

A REMEDY IN THE TREATMENT OF
RHEUMATISM, GOUTY DIATHESIS, ETC.

Dr. A. Garrod, the well-known English authority on Gout, who was the first physician to introduce the Lithia Salts in the treatment of Gouty Diathesis, states that their action is materially increased by being administered in a *freely diluted form.*

This effervescing salt of Lithia furnishes an easy and elegant way of applying Dr. Garrod's methods.

INGLUVIN

A SPECIFIC FOR VOMITING IN PREGNANCY.
A POWDER:—PRESCRIBED IN THE SAME MANNER, DOSES & COMBINATION AS PEPSIN
In Doses of from 10 to 20 Grains,
AND A POTENT AND RELIABLE REMEDY FOR THE CURE OF
Marasmus, Cholera Infantum, Indigestion, Dyspepsia and Sick Stomach,
caused from debility of that organ. It is superior to the Pepsin preparations, since it acts with more certainty, and effects cures where they fail.

Mellin's Food
For Infants and Invalids.

A SOLUBLE DRY EXTRACT of Barley Malt and Wheat, for addition to Fresh Cow's Milk.

Prepared upon the principles advanced by the eminent chemist, Baron Justus von Liebig.

EXPERIENCE — the supreme test — has absolutely proven that the best solution of the problem of infant feeding was made by LIEBIG, and that MELLIN'S FOOD prepared with milk is the nearest approximation to, and is the BEST SUBSTITUTE for, Mother's Milk which has ever been devised.

THE DOLIBER-GOODALE CO., BOSTON, MASS.

Most Powerful Purgative Water Known

1/4 THE QUANTITY REQUIRED BY OTHERS

ABSOLUTELY HARMLESS AS IT CONTAINS ALMOST EXCLUSIVELY SULPHATE OF SODA.

NO REPULSIVE SMELL NOR BITTER TASTE

NO CRIPES

VILLACABRAS

NO PAIN

Clinical Lectures.

PLEURISY WITH EFFUSION.

By J. M. ANDERS, M. D., PH. D.,

PROFESSOR OF THEORY AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE AT THE MEDICO-CHIRURGICAL COLLEGE, PHILADELPHIA.

Gentlemen:—The patient before you is a painter; age 40; single; born in United States. The resident physician, Dr. Hunter, has obtained the following notes of his case and previous history: The mother died of throat consumption at the age of 70; father is still living and well. Three sisters have died of phthisis, at 26, 36 and 35 years respectively; one brother died of phthisis at 48 years of age. There is no other hereditary disease in the family. The patient has always enjoyed good health until the onset of present illness, which occurred about January 1st, 1892. The first symptoms were those of la grippe, viz: cough, aching of the bones, slight febrile movement. After 10 days he developed such symptoms as stitch-like pain in the left axillary region, dyspnœa, with catching respiration and at the same time there was a slight increase of temperature. The physical signs of pleural effusion were noted by the physician in attendance at that time. The cough was hard and harassing, with very slight expectoration. He was confined to bed for 6 weeks from the date of onset. Since he left his bed, 4 weeks ago, the cough has gradually diminished, while he has gained 4 pounds in weight. He still has slight cough, slight pain on deep respiration and moderate dyspnœa on exertion. He has never had night sweats.

One week ago, we noted the following physical signs: on inspection, the lower half of the left chest was observed to be somewhat retracted posteriorly. The expansile movements were slightly increased on the right side and over the upper portion of the left. Over the lower half of the left side the movements were very slight indeed. No retraction was noted anteriorly, or in the left axillary region; only posteriorly.

On palpation, the vocal fremitus was found to be normal on the right side and over upper two-thirds of left side posteriorly. Anteriorly, vocal fremitus slightly exaggerated over upper portion of left side, whilst over lower lobe of same side laterally and posteriorly, almost totally absent.

Percussion resonance everywhere slightly exaggerated except over lower portion of left side, where there was dullness even to flatness. The vesicular murmur was also slightly exaggerated over whole of right side and upper portion of left. Over lower portion of left side posteriorly and laterally, very feeble respiratory murmur was heard and at the extreme base, none at all. A pleuritic friction and creaking sound was heard in mid-axillary region. Near the base posteriorly, we heard crepitating friction sounds.

But, gentlemen, the one physical sign which is of infinitely more value than all those before mentioned combined, is the change in the upper limit of dullness on change of position of the patient. Whenever this is noted, we may be certain that the pleural cavity contains fluid. So soon as this fact was made out in the case before you, we confirmed the diagnosis of liquid effusion by the use of the hypodermic needle, by means of which we withdrew a small amount of straw colored fluid. The patient was treated by the use,

internally, of the so-called iodides, as per the following recipe:

℞ Potassii iodidi.....gr. v.
Syr. ferri iodidi.....m. x.
Syr. sarsap. comp. q. s. ad.....5i.
M. Sig. 5i q. d.

He returns to-day feeling rather better than when he presented himself for treatment one week ago. On making a careful physical examination of the left chest, it was found this morning that the amount of effusion had, within the past week, diminished to a noticeable extent, as the result, probably, of the treatment instituted one week since.

I had informed the man, after examining him for the first time, that in case the liquid effusion did not subside in the course of one week, I would resort to aspiration. However, since there has been considerable subsidence of the upper boundary line of dullness, it would not be the part of wisdom to interfere in this mechanical manner. His general condition is apparently very good; he has not had, for several weeks, any marked rise of temperature, indeed, as often as the temperature has been taken during this period, it has been found to be under 100° F. whilst to-day it is only 99° F. The cough has almost entirely disappeared and the dyspnœa is also less marked on exertion. In view of the fact that he has steadily improved since he came under our care, we will continue the double iodides for at least two weeks longer. His diet shall be generous; he shall take a moderate amount of exercise in the open air and shall avoid exposure to wet and cold, and shall take a moderate amount of alcoholic stimulants in the form of milk punches.

Gentlemen, the history of this case represents several features of considerable interest. You may recollect that he gives the history of a well marked hereditary predisposition to tuberculosis, his mother, three sisters and a brother having died of the latter disease. Whilst the etiology of sero-fibrinous pleurisy is not very well understood as yet, there is a large number of competent observers who contend that in the vast majority of instances, this disease is secondary in the course of tuberculosis. I myself am of the opinion that pleurisy is very rarely a primary affection, and that it is more frequently a secondary process in chronic tuberculosis than in any other disease, though I cannot go so far as many French writers, who contend that all pleurisies are tubercular. It is not to be inferred that pleurisy is non-tubercular in nature when gross lesions cannot be demonstrated in the lungs, since it has frequently been found that a very small tubercular infiltration of the pulmonary tissue has been followed by active inflammation of the pleura, indeed, we have no means of eliminating phthisis as a causal factor in cases of pleurisy. This is also shown by the fact that sero-fibrinous and plastic pleurisy are often the first step in tuberculosis. Here it is quite probable that the tubercular process is the primary one, it having merely been overlooked. We must, at all events, concede the fact that tuberculosis predisposes markedly to inflammation of the pleura and that the case under consideration is no exception to this law. Among children, pleurisy, according to my own observation, is less frequently tuberculosis in nature than among adults, though it much more frequently follows pneumonia.

I have just learned, a few moments prior to bringing this patient before you, that he is addicted to the immoderate use of alcoholic stimulants, and has been for many years. I mention the fact in this connection, for the reason that I sincerely believe that chronic alcoholics are very prone to suffer from attacks of pleurisy. You will not find chronic alcoholism put down in most of your text books as a causative factor in this disease, but I am convinced that a little careful observation will lead you to a similar conclusion.

We found that this patient suffered from influenza for ten days prior to the development of the pleurisy. Pleurisy, it should be recollected, occurs quite commonly in the course of all acute infectious maladies, and this is especially true of influenza. Every medical practitioner who enjoys a large clientele, must have observed, during the epidemic through which we have just passed, many instances in which pleurisy developed either in the course of, or subsequently to, cases of influenza. Influenza is to be looked upon, however, rather as a predisposing, than as an exciting cause of the disease. There is nothing in this man's history that would throw light upon the question of the immediate or exciting cause of the disease. Pleurisy may very frequently be traced to exposure to wet and cold, as well as to injuries to the chest wall.

The diagnosis of sero-fibrinous pleurisy is not difficult when the amount of effusion is large. Considerable difficulty is, however, presented when the effusion is small in amount or confined to limited areas on account of adhesions. So far as the subjective symptoms are concerned, it should be especially noted that they do not stand in any sense in direct relation to the extent of the effusion. I have frequently seen cases in which the amount of effusion was large, whilst there was almost entire absence of such symptoms as pain, cough or dyspnœa; the symptom, pain, is especially misleading. On the other hand, cases often present marked subjective symptoms, notwithstanding the entire absence of liquid exudation, to be very carefully noted, since they are occasionally of value when we come to discriminate between this disease and acute lobar pneumonia. Under these circumstances, the physical signs do not betray very clearly, under certain conditions, the true nature of the morbid process within the chest. As a rule, however, the physical signs are quite diagnostic of pleurisy with effusion. This is particularly true, as before stated, when the amount is copious. Here, the well known signs, viz., restricted expansile movement on inspiration, bulging, the absence of vocal fremitus on palpation, the flatness on percussion, the absence of or greatly enfeebled vesicular murmur, together with diffused bronchial breathing over the upper portion of the effusion, usually suffice to make a positive diagnosis. In the patient before you, when first seen, the amount of effusion was small, and it is under these circumstances that errors are frequently committed, simply through lack of due precaution in carrying out the well recognized methods of exploration, rather than from lack of skill. Had I discontinued my examination, of this case before ascertaining whether the upper boundary line of dullness shifted with charge in the position of the patient, I should have made an incorrect diagnosis, for, up to this moment, I was of opinion that we had to deal with a thickened and adherent pleura simply. Having found, however, that the upper line of dullness changed on changing the position of the patient, I was obliged to make the diagnosis of pleurisy with slight effusion. Too much stress cannot be laid upon the importance of applying this crucial test in cases in which the effusion is slight. It may not always be possible to make it even though a certain amount of liquid be present, more particularly if that should be sacculated. Under these circumstances, before concluding that no effusion is present, I would advise you to resort to the use of the hypodermic needle, which, if employed under antiseptic precautions, can, in the first place, do no harm, and will very frequently discover for you the presence of effusion, a condition of things that would otherwise be frequently overlooked. It is owing to the fact that the recognition of effusions however slight is of the utmost importance when we come to treatment of this affection, that I have placed so much emphasis upon this point in diagnosis.

I cannot to-day take up the subject of the differential diagnosis of this disease. I should like to call your attention to a few practical suggestions in connection with the treatment of this common complaint. In approaching the question of the management of this disease, it is all important to bear in mind that the effusion is the result, primarily, of an inflammatory process and is not a mere transudation. That inflammatory process is, within certain limits, self limited, most probably. If this be true, then one of the aims of the physician should be to limit the extent of, as well as the intensity of, the inflammation, by this means also limiting the amount of effusion. With a view of combatting the inflammation, we employ external as well as internal means. Locally, the use of counter irritants, such as mustard plasters, iodine, etc., are of value. Internally, there is perhaps no other remedy that fulfills so many indications as quinine; it should be given in doses of four grains every four hours. I would strongly advise against the use of internal antipyretics in the treatment of this disease, more particularly such as antifebrin, antipyrin and phenacetin. We are not certain of our ground as to whether, in this complaint, there is a toxic agent circulating in the blood and exerting a poisonous effect upon the heart, its ganglia and the nerve centers, but we do know that the heart is very much embarrassed on account of the liquid effusion displacing it and compressing the great vessels near it, and we do know further, that the blood pressure in this disease is usually quite low, as shown by the

small amount of urine secreted daily; hence, to depress still further the center of circulation, is not only uncalled for, but positively injurious. My reason for saying that internal antipyretics are not called for in this disease, is that the temperature is rarely above 103° F, and can be sufficiently lowered in a safer manner by the use of cold sponging of the surface and the use, internally, of quinine. Neither would I recommend the use of any of the arterial sedatives, for the reason that they too, in every instance, depress the circulation whilst relaxing the blood vessel walls and lowering arterial tension,—the very things that are to be scrupulously avoided in this disease. Another leading indication in the treatment of pleurisy has for its object the removal of the effusion. This may, in a great many instances, be left to nature herself. It is questioned, by some authorities, whether we can, by the use internally, of medicinal agents, stimulate absorption of the effusion, and whilst time will not permit me to enter into a discussion of this mooted question, I desire to state it as my honest opinion, that much can be done in this direction. I would advise especially, that you make trial of the mixture already rehearsed in your hearing. This has been employed by myself in not less than thirty cases, with apparent success; at all events, in nearly every instance in which the double iodides have been used, thoracentesis has been unnecessary.

The fluid should be withdrawn by mechanical means at any time during the course of a case of pleurisy when dyspnœa becomes urgent; when there is a tendency to syncope; when lividity of the eyes, lips and finger tips become marked, no matter how high the temperature. But unless the indications during the febrile stage are urgent, unless demanded on account of threatened asphyxia or syncope, it had better not be done, for the reason that when performed during the active inflammatory stage of the affection, there is apt to be a rapid return of the effusion. It is often a difficult question to decide how soon to aspirate after the temperature has declined to the normal or to a point near the normal, especially when there has been no noticeable diminution in the amount of effusion present. Under these circumstances, the leading indication is to get rid of the fluid, and if you have persisted in your efforts to assist nature to absorb this fluid by the exhibition of remedies recommended for this purpose, during the entire course of the febrile stage and for one week subsequently, then I would advise you not to delay the operation of thoracentesis any longer. At your first operation, remove but a small portion of the effusion, at the same time continuing the use, internally, of the double iodides previously recommended. If, however at the end of another two or three days, no tendency is shown on the part of the effusion to subside, then a second aspiration should be done. The necessity for the removal of a large amount of effusion at any one time rarely exists, and the dangers that attend such a procedure are several, among the most serious being albuminoid expectoration and syncope, which are ofttimes almost immediately fatal, whereas the removal of a small portion of the effusion (say from 8 to 12 ounces) can do no harm if carried out under antiseptic precautions, no matter how frequently repeated. Again, frequently have I seen a single operation at which a small amount of the effusion was removed, suffice. More frequently perhaps, a second aspiration was required.

TREATMENT OF TORTICOLLIS BY THE HYPODERMATIC INJECTIONS OF ATROPINE.

Leszinsky (*Revue de Therapeutique Medico-Chiurgicale*, 1891) has published a case of muscular torticollis, which was successfully treated by hypodermatic injections of atropine. The patient was a painter, 37 years old, in whom the affection developed without appreciable cause, perhaps under the influence of lead intoxication. The contractions were exaggerated by the movements of mastication, by the closing of the jaw, and even awakened the patient from sleep. Near the right angle of the mouth there was a point of complete anæsthesia. After having used various internal remedies and electricity without effect, the author made injections of atropine, beginning with $\frac{1}{100}$ of a grain and increasing gradually to $\frac{1}{75}$. The cure was complete after eight injections. The author mentions a case of convulsive *tic* in a woman of fifty years, in which similar injections produced decided amelioration.—*Univ. Med. Mag.*

SURGICAL INTERFERENCE IN CEREBRAL DISEASES OF CHILDREN.

By FRANK PARSONS NORBURY, M. D.,
JACKSONVILLE, ILL.

It is the object of this paper to consider the advance made in the pathology and surgical treatment of the cerebral diseases of childood. It is not deemed necessary to recite the history of this progress, nor to enter largely into the discussion of the theories upon which much of the modern surgical interference is founded. There can be no question as to the advisability of interference by surgical means, when the known pathological conditions are such as to warrant the hope for improvement. But gross theoretical speculations, as to the pathology, such as have been advanced relative to microcephalus are not scientific aud are not sufficient to permit of operative procedure. Starr has aptly said, that the solution of the problem of operative treatment in cerebral diseases of childhood must be based upon these conditions: *First,* the pathology of the cases, and *secondly,* upon the results of experience when such operations have been done. The pathology of affections peculiar to childhood, has not received the study it deserves by operators and others advocating surgical interference; especially does this apply to microcephalus, the relief of which, by linear craniotomy, is now being strenuously advocated by surgeons on both sides of the Atlantic. While Lannelongue has modified the original theory, that advocated by Virchow, viz., that microcephalus was due to premature synostosis, by saying that the condition is due to maldevelopment in the cranium, and is secondary, yet, he persists in doing the operation, hoping thereby to stimulate brain growth. Microcephalus is a true pathological condition having intra-uterine arrestments of development as a cause. Whether disease of the fœtus, or nutritive changes from other causes, are primary in producing this result, we are unable to say. There is deficiency of structure as well as malformation of the brain, and synostosis is not a factor in producing this narrowing of the brain in all its diameters.

Concomitant as it is in almost all cases, yet microcephalus may exist without it. Down, of London, reports cases of microcephalus where the sutures were not closed, even the medio-frontal suture which is ossified during the first year of life, was open. He says, "In my own observation of the crania of two hundred idiots, the arrest of development was not the result premature ossification of the sutures." He further says, in speaking of one particular case, "I am desirous of placing on record this extreme degree of microcephalus, without any synostosis, as a striking example, in which other than mere mechanical causes, must be looked for as productive of this and analogus cases."

Shuttleworth, after reporting a similar case, says, "I am inclined to think that the premature synostosis is as a rule the consequence rather than the cause of imperfect brain development, and that the arrest of growth is about the sixth month of gestation."

Fletcher Beach supports this view; so also does Ireland, who says in many microcephalic heads the fontanelles are open and the sutures not united.

To Wilmarth we are indebted for much of the advancement made in the pathology of idiocy; he in his extensive autopsies has found but one case where any brain compression existed, while in most cases the convolutions were full and rounded. In a private letter to me he says, "There is very little evidence that microcephalic brains result from compression from the skull, but on the contrary there seems to be in nearly all cases an extra amount of subarachnoid fluid, with no flattening of the convolutions, or other indications of intra-cranial pressure, as if the skull had grown slightly beyond the brain. If the conditions arose from cranial pressure, all portions of the brain should suffer alike, as the brain may be regarded as fluid, so far as transmission of pressure is concerned. I agree with you that the defective growth is more often due to nutritive faults, which we do not at present understand."

My own studies based on anatomy, embryology, pathology and clinical obser-

*Read before the Section of Neurology and Medical Jurisprudence of American Medical Association, June 8th, 1892.

vation have convinced me that in microcephalus we have to deal with conditions not amenable to treatment by surgical means. Anatomically speaking we recognize that intellectual development depends, as Meynert says. on the uniform structure of all parts of the brain. In microcephalus, we find absence of critical structure, necessary to normal mental development, and that the degree of idiocy is not dependent so much upon the degree of microcephalus, as upon the amount of structural deficiency. The smallness of the skull is no criterion of intelligence in these defectives. The structural deficiency is shown in effacement and interruption of convolutions, the simple and defective arrangement of fissures, the absence of the central portions of the brain, and atrophy of the lobes, especially the frontal and occipital. Microscopical examination shows diminution in number and absence of ganglionic cells in certain layers and deficiency of nerve fibres.

Embryology teaches us that the brain is developed early, but that it is not until near the fourth month the most important portions are shown, then it is the frontal, occipital, parietal and temporal lobes can be distinguished and the primary fissures are pronounced. The secondary fissures appear between the fifth and sixth months; the occipital lobe should cover the cerebellum at the sixth month, according to Beaunis and Bouchard. In the seventh month nearly all of the main foldings of the hemisphere come into view, the frontal lobe elongates, the sylvian fissure narrows to a cleft. In view of these established facts we conclude from observation of the brains of microcephalics, which in so many cases show evidences of arrestment, before the evolutionary processes above stated are completed, that arrest of development occurs at, or near the sixth month of gestation. An embryological study of the process of ossification does not sustain the theory that synostosis is the cause of microcephalus.

Embryology, shows that the vault of the skull is formed in membrane and the base in cartilage, and pathology often makes the distinction more manifest (McClellan), which it does in microcephalus; the ossification in the base is well advanced at birth, and the vertex may or may not, be completely ossified, according to the precocity of the osseous system, "existing without any correlation between the growth of the brain and skull." Wilmarth says, "I am convinced that in the majority of cases the skull does not grow simply because the brain does not." My own observation is that skull growth is dependent upon brain growth only to the extent of localized nutritive interference, which while it may affect both brain and skull, does not necessarily do so as evidenced in synostosis and also in open fontanelles in microcephalus. We conclude that synostosis is the result of arrested brain development, without interference with the process of ossification. The results of experience when the operation of linear craniotomy has been performed, do not sustain the claims made for it, by Lannelongue and his followers. Statistics of operations performed, which I have been able to gather, show such meagre results and such great mortality both in this country and Europe, that it seems to me folly to continue to advocate linear craniotomy. Those who have survived the operation have in some instances, improved but there is no evidence to show that such improvement would not have taken place by as persistent efforts in training before the operation as after. Time, that important element which should be taken into consideration in estimating the results of linear craniotomy, has been lost sight of in the haste to report the operation. The efforts put forth to elicit improvement, and the attention given the child by the parents and all interested in the case would even in the most profound case of feeble-mindedness, have some noticeable mental improvement as a result. Those who are familiar with the training of feeble-minded children, have found no encouragement in the operation and one after another have assured me they have little "sympathy with that kind of surgery."

Persistent physiological education such as is to be had in thoroughly equipped institutions can accomplish more without linear craniotomy as an adjuvant.

The treatment of epilepsy has received much attention during the past year, both by surgeons and neurologists, and while our knowledge of the pathology of this disease, is still very obscure, we have advanced appreciably, as to the value of surgical interference.

All who are familiar with epilepsy are aware of the persistency of the attacks in

spite of all treatment, and how comparatively few cases are cured, clinical reports to the contrary notwithstanding. In a paper read before the Illinois State Medical Society last year, on epilepsy, I said, "All we do generally in the treatment of this disease is to render less frequent and less severe attacks; the removal of peripheral irritation makes the case more hopeful, but statistics are not encouraging as to the complete recovery, probably due to the establishment of the epileptic habit, which is due to the adjacent brain centers having become irritable and unstable." These statements were severely criticized, my prognosis was said to be too gloomy, and the outlook for epilepsy too discouraging.

Another year's observation and study only confirms my belief more strongly, for epilepsy is, as yet, a Gordian knot for the neurologist and surgeon to untie. Gray, Sachs, Ferrier, Dana, Wilmarth, and other authorities have contributed to the literature of epilepsy clinical observations which sustain my humble opinion. Surgical interference is justifiable and should be advocated in all cases of traumatic or organic epilepsy, providing sclerosis is not too far advanced.

In focal epilepsy we cannot predict the results following excision of the localized seat of irritation, *first*, because conditions more severe than the epilepsy itself may follow removal of the cortical substance: and, *second*, we cannot give assurance of the cessation of the spasms. I have in mind a case to which the first statement applies; a boy, an epileptic; trephined, and portion of cortex removed, the epilepsy ceased, but the boy became an imbecile, and is now an inmate of an Institution for Feeble-Minded Children. My second statement is illustrated by another case, a boy; trephined, epilepsy still continues; fits are more severe, and this boy has since been admitted to a Feeble-Minded Institution. We must not overlook the fact, that injuries comparatively slight and which would do little if any damage to the brain of an adult, in a child produce disastrous effects, and diffuse sclerosis results. Wilmarth, in his autopsies, has repeatedly demonstrated this fact, and while associated with him I had this so impressed upon me, that I am loth to advise trephining in the epilepsies of childhood, unless taken very early in the history of the case, and even then we cannot offer much hope, for as Wilmarth says of his cases, "My post-mortem studies have led me to believe that while considerable injury may be inflicted on the adult brain with no great impairment of the mind resulting, the contrary holds in the child and brain injury from accident or disease is sure to permanently impair mental growth." Osler, likewise pointed out to me during his study of the cerebral palsies of childhood, the very diffuse formation of blocks of sclerosis and the improbability of surgical relief.

In his book, he says, "There are several circumstances which militate against the probable success of operations of this kind. When sclerosis exists the area is usually too large for removal, and it is only in exceptional instances we could expect the epilepsy to be relieved. I do not think that in any of the cases which I have reviewed, the anatomical condition offered the slightest possibility of relief from interference."

What then is to be the future of surgical interference in the epilepsy of childhood? We must be guided by the nature of the case; often no doubt we can by operating arrest the progress of the disease, perhaps cure it. Further, as Sachs says, in the cerebral palsies of childhood, the paralysis which so often precedes the epilepsy will be the guide for operative procedure by localizing the irritation; the centres should be exposed and be treated in accordance with the special indications of the case. He is confident that if these cases of infantile cerebral palsies are more generally recognized, and if we succeed in checking the tendency to epilepsy in them, the total number of epileptics will be notably diminished.

Operative interference in cases of defective sensory perception, as presented by Starr, in a recent paper on "Cerebral Atrophies of Childhood," seems to me to open up a field for observation for the neurologist, one promising some benefit in preventing, or at least ameliorating the condition of that great class of defectives, the blind, and the deaf and dumb. We all know that many, many of these cases, especially of the deaf and dumb, owe their trouble to cerebral diseases—diseases which medical treatment has failed to relieve, and we cannot but hope that surgery may ultimately find a way to benefit this unfortu-

nate class. Deaf-mutism is little understood and less studied by the neurologist, in fact a thorough ætiological study of this prevalent condition from the standpoint of neuro-pathology has not been scientifically undertaken.

Through the kindness of Dr. Gillett, Supt. of the Illinois Institution for the Deaf and Dumb, the largest institution of its kind in the world, I have commenced the study of deaf-mutism and hope to report my progress at the next meeting of this Association.

In conclusion, I would say surgery has its field of usefulness in cerebral diseases of childhood, but is limited by the pathology and the degree of success following operations. To scientifically recommend surgical interference, we must be sure of our diagnosis, and permit of extreme limits in our prognosis.

EFFECTS OF AN OVERDOSE OF CODEINE.

An overdose of codeine is not a common occurrence, and therefore Dr. Mettenheimer, who has met with such a case, has reported it. An elderly lady consulted him for a slight catarrhal, nonfebrile affection which, however, gave rise to a troublesome, spasmodic form of cough. For this he prescribed 0.03 gramme (about half a grain) of phosphate of codeine, in the form of a pill, to be taken every three hours. The patient, however, swallowed four of these pills, or about a grain and a half of the codeine salt, at once. Shortly afterwards she vomited twice and suffered from abdominal pain. There was, too, suppression of urine and she felt very ill, being sleepy but unable to go to sleep. The next day she was still drowsy and had no appetite but there was no return of the sickness. She was then seen by Dr. Mettenheimer, who found the pupils contracted, the pulse hard and quick, and the respiration accelerated. The cough had entirely disappeared. The contracted state of the pupils, the loss of appetite, and the abdominal pain persisted for several days. No urine was passed until thirty-six hours after the pills were taken. On the third day the drowsiness had passed away. The cough did not return for a week and when it did it was comparatively slight. This case seems to show that codeine in large doses has a very similar effect to opium and that it may prove a most efficient remedy for some kinds of cough. As the tongue remained clean it would appear that the vomiting was due to cerebral, rather than to gastric, irritation.—*Lancet.*

TYPHO-MALARIAL FEVER SO-CALLED.

By W. B. YOUNG, M. D.,
BON AIR COAL MINES, TENN.

In presenting this paper I shall claim no originality, nor attempt to produce anything new. The nomenclature of this disease is quite varied. Wood calls it "entero-miasmatic;" Drake gives it the name of "remitto-typhus;" Loomis calls it "continued malarial fever," and Woodward gave it the name "typho-malaria" by which it is best known through the Southern States. I believe that all of the above appellations are erroneous and misleading.

During the four years of my professional life it has been my good fortune to meet with and treat at least ninety cases of this fever that could easily be excluded from all other well recognized diseases. All of these cases were well developed, presenting well marked symptoms characteristic of this, so-called "typho-malarial fever." Doubtful cases were omitted. I shall give only the leading symptoms of this disease as I observed them, for I hope not to bore you by presenting facts with which the greater majority of this Association are already so well acquainted.

My experience with this disease leads me to believe: (1) That this fever occurs most frequently in the last month of summer and in the three fall months.

2. It occurs usually in the young and middle aged, very rarely in the aged.

3. The disease is very rarely found among the African race.

Symptoms.—The patient usually complains for a few days of being weak and of his head or back aching. Then perhaps he will have a chilly sensation with high fever following. The temperature course reaches its maximum, most usually, the first or second day. Then it will drop perhaps a degree or two and continue at this stage for from two to five weeks, I have had a few cases that had fever for six weeks. The pulse and temperature usually preserve a normal ratio. Sometimes we have diarrhœa, but most generally constipation. When diarrhœa occurs it is easily controlled by judicious treatment. There is nothing especially characteristic about the stools as observed without the microscope. Occasionally we have a case with a little tympanites. No tenderness nor the characteristic gurgling of typhoid in the right iliac region. No rose colored spots. The urine is always scant and usually high colored, but not turbid. It was not tested by the microscope. The middle and back part of the tongue is usually coated by a light fur, sometimes there is a yellowish white coating. The papilla of the tongue is almost always very prominent, its tip red and strawberry-like. Sometimes edges red. Often it is considerably pointed, at others quite flat and flabby. No sordes on the teeth; gastric disturbances usually occurred in children, not so frequent in adults. When delirium occurs it is most usually during the first few days when the fever is highest. Occasionally we have hepatic tenderness and vomiting of bile. No subsultus tendinum. The only special symptom after the first two or three days of which the patient complains is that of a general feeling of exhaustion, as if they were "completely worked down." It is not often that they complained of inability to sleep and rest at night. This is very striking in the great majority of cases; sometimes it is the reverse. Out of ninety cases I lost two; one died from hæmorrhage of the bowels, the other from heart failure. My treatment is generally expectant. I know of no specific, nor any regular course of treatment like we have in malaria and typhoid. I usually open the bowels with a small dose of calomel followed by a gentle laxative. In my first experience with this fever, I pushed quinine, thinking that it was of malarial origin, but without effect. I have never been able to attribute any good results to this drug in treating this disease. Nitro-muriatic acid is a great favorite with me in treating such cases, it aids digestion and assimilation. Sometimes if a dry tongue and tympany develop I give turpentine emulsion. My experience with this disease is that we must guard against heart failure. There is almost always a great "prostration of muscular strength." Even in the mildest cases it is some weeks before the patient regains his former strength and power. The muscles of the lower extremities seem to be especially affected in this fever. To see a patient

*Read before Tennessee State Medical Society, April 1892.

when recovering attempting to walk reminds me of that muscular prostration following diphtheria. For the cardiac weakness, I sometimes use digitalis, oftener during my former experience than during the last year. As Dr. H. C. Wood states, so I believe, that in a great majority of cases it "impairs the irritability of the sensory and motor nerves and muscular fibre, and interferes with reflex actions, efffects that cannot fail to retard nutrition."

When I find the capillary circulation slow, the pulse very fast and weak, and other symptoms "evincing depression of the excito-motory nervous centres," I generally give strychnia. Alcoholic stimulants are also used with splendid effects in such cases. I have now given the most prominent symptoms of, and my general course of treatment in, the so-called typho-malarial fever. The symptoms of this fever, as I observed them, clearly simulate the description of the so-called mountain fever of Colorado, given by L. Hubers M. D., of Rockyford, Colorado, in *The Medical News* of September 20, 1890. I believe the two fevers are produced from the same poison, the apparent difference being due to climate, altitude, etc. In speaking of this fever he says: "I am quite certain that I first observed cases of the so-called mountain fever in the Arkansas River valley in Western Kansas. There it was not known by the above appellation, nethertheless, several years' experience with the disease convinces me of its identity with 'mountain fever.' Dr. Huber does not tell us what this fever was called in Western Kansas, but from his description I understand that it was the so-called typho-malarial fever.

My principal object, as stated above, in preparing this paper is, that I desire to state my lack of faith in all former theories of this disease, with one exception. The theories as presented to the profession heretofore are about as follows:

1. That it is a hybrid disease.
2. That this so-called typho-malarial is a mild manifestation of typhoid.
3. That it is a combination of both the typhoid and malarial poisons.
4. That it is "a distinct type of specific fever."

In answering the first theory it hardly becomes necessary to state that we have no such thing as a hybrid disease. No really scientific investigator has ever come to such an irrational conclusion. All standard authorities assume that it is no hybrid; neither do I believe this to be a mild form of typhoid. All who take this view have so far furnished us with but little proof to substantiate their position; their arguments are by no means complete or convincing. It has been more of the nature of assumption than proof. They have not attempted to prove their affirmation by bacteriological investigations, nor from the pathological anatomy in such cases. Even the eminent Loomis (Practice of Medicine) in his concluding remarks on the morbid anatomy of this disease, says: "While therefore no pathological lesions which can be regarded a characteristic of this type of fever are found, and while the lesions very closely resemble those of typhoid fever on the one hand and remittent fever on the other, still there are differences which are sufficient to distinguish it from both and to stamp it as a distinct type of fever. By far the ablest plea for its being a mild type of typhoid was presented in the *Medical News*, of June 12, 1890, by Dr. W. W. Johnson, of Washington City. He seems to take it for granted that it is the result of the typhoid poison, and fights for his theory on the defensive order in endeavoring to exclude the malarial poison. He says in his argument for the exclusion of the latter poison, "The strongest arguments for the theory of the two diseases in one individual, are the presence of supposed well defined malarial symptoms in typical enteric fevers, and the beneficent effects of quinine in such cases. "To the first of these arguments it may be answered that the occurrence of chills in the onset or during the course of enteric fever, marked remissions in the fever curve, gastric irritability, the vomiting of bile, icterus and hepatic tenderness, are not necessarily due to malarial infection, and may and do occur in the course of the enteric fever of localities where malaria is unknown."

To the second argument, I will state that in my experience quinine has had no control over this disease whatever. It has not influenced the course or duration of a single case, to my knowledge. Dr. Johnson says that the symptoms so closely simulating those produced by the malarial virus are not necessarily due to this poison, for the reason that such conditions are

present in diseases where we know there is no malaria present, why not put the typhoid virus to the same test for exclusion in this disease. Do we not often find in many other diseases symptoms simulating those of typhoid fever where we have every reason to know that the specific virus is absent?

There is rarely the distinct pathological lesion of typhoid, neither is there anything characteristic about the stools from a bacteriological nor pathological investigation. Then why do so many of the profession continue to call this modified typhoid when they have so little grounds for so doing.

The third position I believe to be as fallacious as the other two. It is hardly reasonable to suppose that we have a mild form of fever produced by the preying upon the system of two distinct poisons. At the same time, I think that we have clearly proven that there is at least room for skepticism in regard to the presence of the typhoid virus in this disease, even from the confession of those who believe it to exist, and we think it just as unreasonable to claim the presence of the malarial germ as that of the typhoid poison; however, I believe the larger majority of textbooks take the position that in this fever we have the malarial agency; and that it is really "modified malarial fever" instead of "modified typhoid fever." Dr. Bartholow does not think this a distinct type of fever, simply typhoid complicated by malarial poison. Dr. Sam. M. Bemiss, of New Orleans, in Pepper's System of Medicine, vol. 1, page 614, in speaking of this fever says: "The prefix *typho* is properly applicable to a class of malarial fevers which are complicated by the specific poison which produces typhoid fever," and that the term (typho-malarial) should be so restricted as to define a disease compounded of the two pathological factors which, when acting separately, produce either typhoid or malarial fever." We think this is a definition calculated to mislead. Dr. Bemiss does not bring forth any very convincing proof to show either the presence of malaria or typhoid. He seems to take it for granted that "these things are so."

The presence of malaria is not evinced from the pathology of the disease so far as I have been able to ascertain. The effects of the anti-malarial treatment as advised by most authors does not go to prove that the malarial virus is present.

We believe that our authors of the present day too often receive the tradition of our forefathers and jump at conclusions in regard to the ætiology of this disease. They take too much for granted and are too easily convinced of the presence of certain poisons merely from physical signs. To show you the truth of the above assertion, I wish to make a quotation from the clinical lectures of Dr. Nathan S. Davis in his lecture on "Continued Fever." In presenting to his class a certain case of fever, he states: "The early history of the case (a chill followed by a paroxysm of fever) together with the existing paleness of skin and exacerbating character of the febrile phenomena *show the existence* of a malarial influence."

Is this proof sufficient to convince a thinking mind that the malarial parasite was in the blood of this patient beyond any question? Might not some septic poison produce the same symptoms.

In diagnosing for a tuberculosis are we content with simply the physical signs? Do we not search for the tubercle bacilli, the morbid anatomy and other corroborating conditions? In answer to a query in regard to typho-malaria," Dr. H. Toulmin, of the John Hopkins Hospital says, in regard to the two diseases being blended together, "that malarial fever and typhoid fever are entirely and perfectly distinct and are never found in combination . . . . We always examine the blood for Laveran's organisms, and test the urine for Erlich's typhoid reaction, which we consider of much value."

We might add that this is the verdict of the best authors from their most recent investigation.

If it be true that we have a modified form of either malaria or typhoid the one by the other, I would like to ask a few questions under the light of Laveran's discovery, pointing to the possibilities of a wonderful revolution in the treatment of malaria and typhoid.

1. If both the malarial parasite and the typhoid virus exist in these cases, why have they not been found in the blood of those persons thus affected? Laveran claims that, "the malarial parasite has never been found in the blood of those not affected with malarial poison." Again, the same investigator says: "The salts of qui-

nine cause the parasite to disappear from the blood, and this takes place synchronously with the cessation of the fever."

We found that in the above ninety enumerated cases that the salts of quinine did not have this effect in a single case, therefore we are forced to conclude that the malarial parasite was absent.

Dr. Osler states that "The characteristic changes in malaria are as distinctly determined in the blood as are those of tuberculosis of the lung in the sputa."

Dr. George Dock, of Galveston, Texas, has made some very interesting investigations along this line corroborative of Osler's statement.

2. If the malarial parasite modifies the action of the typhoid poison why not convert a specific typhoid into a so-called typho-malaria by injecting into the blood of the typhoid patient the malarial parasite. By this means we would lessen the mortality. It seems to me that this would be easily accomplished if the theory be true for the great Laveran again asserts that "malarial disease has been transmitted from one person to another by injecting into the veins of a non-malaria individual a small quantity of blood containing the parasite."

In regard to the fourth theory, that it is a distinct type of specific fever, I am well convinced that this will be the final conclusion of all true pathologists and bacteriologists.

Dr. J. S. Cain, of Nashville, Tennessee, in the last December number of The Southern Practitioner, was the first to boldly advocate the specific nature of this disease. He says: "That it is a distinct type of specific fever bearing no relationship to typhoid and no similarity further than its continuousness and none whatever to malarial fever." He believes that it is produced by a septic agency. Be this as it may, for a final solution of this question we *await* the future developements of the microscopist.

TO RELIEVE HEADACHE.

Weiss (*Prager med. Wochenschr.*, No. 15, 1892, p. 159) has observed that temporary relief from headache could invariably be afforded by pressure upon the abdomen at a point midway between the umbilicus and the ensiform cartilage, the mechanism of which is thought to be dependent upon compression of the aorta.

THE TRUE PATHOLOGY OF SUDDEN DEATH IN ACUTE PNEUMONIA, AND THE BEST MEANS OF AVERTING IT.*

By CHAS. F. J. LEHLBACH, M. D.,
NEWARK, N. J.

The committee on business of last year, in formulating this subject for discussion, have undoubtedly sought to limit it to those cases of sudden death in acute pneumonia which seem to be disconnected from any pre-existing or merely accidentally intercurrent fatal morbid process, or complication. A patient passing through acute pneumonia, with previously existing chronic degenerative nephritis may suddenly be seized with uræmic convulsions, coma, and death; or a sufferer from chronic rheumatic endarteritis of the cerebral vessels may during a fit of coughing in pneumonia be attacked by a sudden cerebral hæmorrhage and die. Such cases do not enter the present inquiry. Their pathology is beyond controversy and there is no preventive means, which may reach them, within our present knowledge.

The class of cases under discussion can best be exemplified by the short recital of one typical case, that of our lamented friend and colleague, the late Dr. Woodhull, of Newark, for a history of which I am indebted to the kindness of Drs. Edgar Holden and Charles Young.

This is Dr. Holden's statement:—"Dr. Addison W. Woodhull, born August, 1831. Died in the Spring of 1876, age 45. One morning he said to me on the street: 'I have a very annoying pain in my left side to-day; I wonder if my old wound is going to trouble me.' He went to New York and before his return took a Turkish bath, and on his return home felt miserable but went on with work; was taken at night with a chill and slight dyspnœa; this was followed by fever, cough and soon rusty colored sputa. Dr. O'Gorman and myself attended him; rapid consolidation of the lung (I think the left) followed.

"The disease ran the usual course of a unilateral pneumonia in a man with sound heart, for I examined not only then, but I before had examined him for life insur-

*Read before Medical Society of the State of New Jersey.

ance, and at that time found no impairment of any organs, save the left pleura thickened and adherent where he had been wounded. My impression is that the chest wound involved only the thoracic parietes, including the pleura but not the lung.

"At about the end of three weeks he was so far convalescent that we said at our morning visit: 'You will not need us any more but we will drop in occasionally to see how you regain strength.' He was able to sit up several times through the day and felt well, had return of appetite, but remarked every day that he could not understand the continuance of the stained sputa. This, from the second day of its appearance, had been not simply rusty, as is usual, but quite red, indeed at times almost jelly-like, and we had frequently discussed the significance of it; but the most careful daily examination had failed to detect any symptom or abnormal sound, rate or area of dullness not perfectly consistent with the diagnosis of acute unilateral pneumonia. We left him on Sunday morning, he saying 'I will be out in a week at the most, and feel well enough to go now.'

"Upon returning from professional calls, I found an urgent message to go to him but found him dead." The following is Dr. Young's statement:

"While passing through Kinney street near Dr. Woodhull's residence, I suddenly heard my name called loudly, and, turning around saw the call came from Dr. Woodhull's house. Rapidly entering I saw the patient within ten minutes, probably less, after the first seizure, which was described as follows: The patient had been sitting up by the window, when he suddenly complained of feeling faint, without any pain, and was assisted by his wife to bed, when he became immediately unconscious, with slow difficult respiration are rapidly cyanosed. When seen by me he was in this condition with hardly any pulse, deeply cyanosed, irregular and slow respiration, eyes rolled upward out of their natural axis, insensible to light; no sign of any convulsive movement. Recognizing the extreme condition of the patient, a free hypodermic injection of ammonia was given with a view, if possible, to stimulate the heart and of its alkalizing effect upon the blood. Within a very short space of time, the cyanosis began to fade and disappear from the forehead down, so that the face assumed a natural hue; the respiratory rhythm was re-established, the pulse came up, so that it became at least distinctly preceptible.

"This condition of apparent reaction, without, however, any sign of returning consciousness (at least as far as muscular manifestations or impressions were concerned) continued for a short time, almost giving hope of a chance for life, but soon he relapsed into the condition, in which he was first found and died."

No autopsy was made. Indeed the absence of records of post-mortem examinations in these cases of sudden death in acute pneumonia forms one of the difficulties in arriving at positive conclusions as to the cause or causes. The clinical history of these cases leave no doubt as to the diagnosis. A fatal termination is to be expected in a certain percentage of cases of acute lobar pneumonia under any circumstances, a larger proportion occurs in private practice, where the surroundings and other considerations of sentiment or convenience forbid the urging of autopsies as matters of simple scientific interest, and thus in most cases we are satisfied with crediting the sudden fatal termination to any of the various lesional possibilities that may occur in pneumonia by embracing them all under the term, heart failure. But, does this explanation explain? Heart-failure as a true direct cause of death can happen in two ways; either by sudden paralysis of innervation through the branches of the pneumogastric nerve supplying it or the inhibitory-ganglia regulating it; or by structural degenerative changes in the heart muscle itself; in the one case the motor power being lost, in the other the motor machine refusing to act, being worn out. Discarding, hence, the term heart-failure as a pathological entity in explaining sudden death in pneumonia, we are forced to look elsewhere. As a guide in which direction to search for the cause or causes two facts should be borne in mind:

1. That these cases of sudden death under consideration, generally occur during or after apparently fully established convalesence, and

2. That the fatal attack is ushered in suddenly and terminates fatally under tumultous signs of a struggle between the heart and lungs, indicating plainly the sudden occurence of mechanical obstruc-

tions in the right heart and pulmonary circulation, as shown by the weak and imperceptible pulse, the dyspnœa, irregularity of respiration, the intense and rapid cyanosis, and unconciousness.

Of all the authors of treatises on pneumonia in the various text-books, so-called, accessible to me the one who comes nearest to a full appreciation of the true cause of this class of sudden death is Flint. He says: "There is a liability in the course of this disease to an occurrence which claims special notice, namely, coagulation of fibrin in the right auricle or ventricle; that is to heart thrombus; this is of not infrequent occurence in fatal cases of pneumonia. It occurs especially when an entire lung becomes involved, and in cases of double pneumonitis."

"Thrombi formed ante-mortem and not infrequently the immediate cause of death, are to be distinguished from those produced in the last moments of life and from post-mortem clots. Their formation sometimes may be determined and with much confidence during life. In a case presenting no symptoms which denote imminent danger a sudden change takes place for the worse; the circulation is notably disturbed as shown by the frequency, feebleness and irregularity of the pulse; there is a sense of the want of air; the expression is haggard and anxious, cyanosis is more or less marked; the patient falls speedily into a moribund state; and this unexpected change is not connected with an extension of the disease to a new lobe or any newly-developed inflammatory complication."

Assuming then that Flint is correct in ascribing heart thrombus as a not infrequent cause of death in pneumonia, although no special emphasis is put on "sudden death" during apparent convalescence, let us extend our inquiry a little further by including embolism of the pulmonary vessels with heart thrombus, or vice versa. If they are found to be the cause of sudden death in numerous and varied other pathological processes there is, for very good reasons to be alluded to further on, no ground to doubt that we here have the principal cause of sudden death in pneumonia. It is not intended to go into an elaborate or exhaustive examination of details. A few facts obtained by a cursory examination of accessible records will illustrate the subject.

Dr. Raywood Johnson in the transactions of the Path. Soc., London, 1889—(*Schmidt's Jahrb.*, Vol. 229, p. 249,) describes the case of a woman fifty-four years old, with varices of leg and phlebitis, who died suddenly in an attack of dyspnœa, of embolism in the pulmonary artery, six to seven inches in length, resting on the bifurcation.

A case of sudden death in a case of typhoid fever by embolism of the pulmonary artery is reported from the *Prazer Viertelzahnsen, in Schmidt's Jahrb.*, Vol 228. p. 215. Autopsy showed tolerably coherent coagula in the main trunk of the pulmonary artery.

A case of sudden death in consequence of formation of thrombus in the pulmonary artery, occurring in a case of acute exudative pleuritis is reported by Dr. Dujardin Beaumet in *Gaz. de Paris* (*Schm. Jahrb.*, Vol. 171, p. 150) death occurred when patient got out of bed to go to stool.

In a paper on sudden death by pulmonary embolism in cases of inflammatory varicose veins, Dr. Marc Chabenat, of Paris, (1874) collected seven (7)cases. In five (5) cases the autopsy showed presence of emboli in the right heart and trunk of pulmonary artery; in the other two cases no autopsy was made, but the history of the case was clear as pointing to the same causes. The author calls attention to the fact that the neighborhood of large venous trunks in which the blood flows yet uninterruptedly favors the detachment of an embolism. In all these cases the emboli were large, as large as a finger, and the detachment of the emboli always took place in the convalescent stage on occasion of sudden movements in bed or when getting out of it.

Two cases of sudden death from embolism and thrombus in the pulmonary artery are reported (*Bullet. de la Soc. Anatom., in Schm. Jahrb.*) due in one case (Dr. Cossy's) to inflammation of the crural vein after operation for strangulated hernia: in the second case, reported by Dr. Hegar, due to thrombosis of the left femoral vein after enucleation of a uterine myoma.

Spontaneous extensive thrombosis of the pulmonary artery caused sudden death in a young chlorotic girl, after a short attack of dyspnœa. Reported by D. H. Rendt, (*Gaz. Hebdom.*, XXXIV, 16, *Schmidt's Jahrb.*, Vol. 215, p. 249). Embolism excluded.

In his inaugural dissertation, Dr. B. L. B. Bang (*Afhandl für Doktorgraden, Schmidt's Jahrb.*, 1882, vol. 195, p. 289) a study of twelve cases of embolism or thrombosis of the pulmonary artery concludes that the most dangerous, i. e., the large emboli, mostly occur in the cases in which the clinical histories show no sign of presence of pre-existing cause.

In a paper on "Sudden Death in Pleurisy" by D. E. Weill (*Revue de Med.*, vol. VII, p. 33, *Schmidt's Jahrb.*, vol. 214, p. 30) the author collects twenty-seven cases of sudden death in pleuritis: in eleven of these cases there was thrombus-formation in the right heart and embolism of pulmonary artery or changes in the myocardium; in six, œdema of the lungs: there was one of pericarditis; in two perforation took place into the lung and in seven cases the autopsies showed no certain cause of death. These latter may have been due to direct heart failure or brain anæmia. In most of these cases death occurred after strong muscular movements—only three died while quietly lying in bed.

Prof. Adolf Lesser of Breslau, in *Vierteljsch fuer faren Mediz., Schm. Jahrb.* vol. 219, p. 74, gives the most important autopsy results in 171 cases of sudden death; only in fifty-three cases an anatomical cause for the suddenness of death was reached; in twenty-one cases there were pressure upon the brain, apoplexy, tumors, hæmorrhage, aneurism; seven were cases of cardiac aneurism; eight times there was suffocative hæmoptysis and bursting of aneurism into trachea; in seventeen cases aneurism was the cause accompaning the fatal result; six were caused by embolism of the pulmonary arteries; in seven cases genuine pneumonia existed, where no direct cause could be found.

In the Medical and Surgical History of the War of the Rebellion, Part 2d, Medical Volume, under the history of acute diarrhœa among the post-mortem appearances noticed, special mention is made of over thirty-six cases in which "fibrinous heart-clots with or without an admixture of ordinary coagula were observed." Two of these cases are noted as having died "very suddenly" and "suddenly." One of these cases died suddenly of pneumonia, and in looking over the details I find that eleven of these cases of heart clot and clots in the pulmonary arteries credited to acute diarrhœa were shown by the autopsies to have been complicated with pneumonia in various stages of progress and intensity, namely cases 162-330-352-353-360-377-385-412-525-642-749.

A cursory examination of the details of cases of pneumonia given in vol. 3d of the same work, is negative as to the occurrence of ante-mortem thrombis or embolism and their bearings to sudden death.

If we assume then, that thrombosis or embolism of the heart and pulmonary arteries constitute the true pathology in a certain number of cases of sudden death in pneumonia, as well as in other diseases —an assumption based upon undoubted facts—we are naturally and logically led to enquire whether the pathological processes and conditions of pneumonia are favorable to their occurrence. Such seems to be the case.

Aside from the undoubted increase of fibrin in the blood in pneumonia, as in acute rheumatism and erysipelas, and its probable greater tendency to coagulation, the pathological processes going on in the minute structure of the lungs in pneumonia themselves are not unfavorable to the occurrence of thrombi and emboli. When the air spaces and bronchi have become fully distended by the exuded inflammatory products and the lung has become solid, when the air vesicles, the air passages, the small bronchi and sometimes the large bronchi are filled and distended with fibrin, pus cells, red blood cells, and epithelium we are told by Delafield and Prudden (Hand-book of Pathology) that "in spite of the pressure on the walls of the air spaces, the blood-vessels in their walls remain pervious." Hence if even a very minute thrombus shall have accidentally formed in one of the small branches of a pulmonary vein, entering into the formation of the vascular network surrounding the air vesicles, this very fact stated by the eminent pathologists cited "that the vessels remain pervious" would favor its detachment and chance of entering the current of blood into the right auricle, thence into the right ventricle, there to become entangled in the pectinated muscles or tendinous chords and to form the nucleus of a rapidly enlarging embolic clot extending, as the case may be way into the pulmonary arteries up to the bifurcation, and leading to sudden death.

Another point in the clinical pathology of pneumonia, particularly in infectious pneumonia, which would favor cardiac thrombus and embolus, is the concurrence of endocarditis with the pneumonia. A moderate degree of endocarditis is, I think, a much more frequent companion of inflammation of the lungs than is generally supposed and than it is possible to clinically prove in all cases. "So long" we are told by Delafield and Prudden "as the endothelial linings of the vessels are intact, a simple retardation of the circulation does not usually suffice to induce coagulation, but changes in the endothelium from a great variety of causes, such as inflammation, degeneration, atheroma calcification and the presence of tumors and foreign bodies favor its occurrence." Thus we see that the existence of endocarditis would favor coagulation.

From what has thus far been stated, it is obvious that whatever means of averting sudden death in pneumonia we may employ, they can only be general and precautionary. The patient should be warned even after the temperature has become normal, not to adopt too soon the habits of fully established convalescence. In fact, he should not be allowed to undergo any muscular exertion or bodily effort, not even the passive one of sitting up, until the expectoration has become of a character to show that the exudative process has entirely ceased and that the degenerative changes in the exudate, necessary for its removal are about completed. The presence or absence of blood, or of its elements in the expectoration may probably be considered an important guide in this direction. Remedial agents should be employed to allay the severity of the cough with its danger that by mere mechanical concussion of the solidified lung any little thrombi in the pulmonary veins may become detatched and enter the current of blood toward the heart and resulting in cardiac embolism and emboli of the pulmonary arteries. Ammonia in one form or another should be given during the whole progress of the disease, not only as one of the most valuable heart stimulants that we possess but also to counteract the tendency to coagulation and the hyperinosis, or increase of fibrin in the blood of pneumonia patients. For the suggestion of the probable good effect of ammonia to counteract the tendency to hyperinosis in pneumonia, I am indebted to my friend Dr. Charles Young. As to the particular preparation of ammonia to be used there may be little choice; but during the last few years my own predilection has been in favor of ammonium salicylate, as it combines the stimulating effect upon the heart with the action of a general blood antiseptic, in cases of infectious pneumonia, and also on account of its good effect in rheumatic endocarditic complication. It can be simply given in ten grains doses every two to four hours.

Having thus opened the discussion on this interesting subject, while I beg that you will pardon me for not having laid before you a more elaborate study, I hope also that you will agree with me, when I say that it should be our duty in every case of sudden death in pneumonia to insist upon a thorough and minute autopsy so that we may know the cause rather than to guess at it.

DOUBLE HÆMORRHAGIC SUBDURAL CYST.

Dr. Newton Pitt showed a double hæmorrhagic cyst before the Pathological Society of London, which was taken from a man aged forty-six, who had suffered for eighteen months with frontal headaches: at night he occasionally had twitchings on the right side. The twitchings were more frequent two weeks before his death; he then became dull, apathetic and increasingly comatose. At the inspection two thin cysts were found in the frontal region in the subdural space, with walls formed of embryonic vascular connective tissue, ¼ mm. thick, containing on the right, six ounces, and on the left, three ounces of serous fluid with recent blood clots. The dura mater was not inflamed. The cysts were attached to the dura mater, but not firmly, and were not attached to the brain. The inner surface was as smooth as that of normal dura mater. The case was a typical example of those cysts whose hæmorrhagic origin was first clearly demonstrated by Mr. Prescott Hewett in 1845. The sources of the hæmorrhage in such cases are from the degenerate cerebral veins in the wasted brains of general paralysis; from either the dura-mater or the pia arachnoid when due to typhus, relapsing fever, and similar conditions producing degeneration of the blood.—*The Lancet,* Nov. 8th, 1891.

COMMON BOILS AND CARBUNCLES.

By P. J. FARNSWORTH, A. M., M. D.,
CLINTON, IOWA.

Early in my practice I stumbled on a successful course of treatment for aborting boils and carbuncles in their early stages and of conducting them to a speedy and painless consummation if not seen until well started.

In the later discoveries of science I have found the reason for my treatment and abundant justification.

If my attention is called to the disease in its pustular stage I apply *unguentum hydragyri.* If they are occuring in a crop several applications are made to a considerable surface. This prevents their recurrence, and aborts those underway. If the boil is fairly begun, is congested. cyanosed and throbbing, "a blue boil" I apply a plaster of *gum opium.* The gum moistened and spread on a cloth or the powder mixed with cerate. In a short time the throbbing ceases, the congestion is removed and in a few hours a circumscribed suppuration takes place (comes to a head at once), the core or nidus comes out. An antiseptic wash soon completes the cure.

If the pustule is judged to be a carbuncle, a plaster made with mercurial ointment (*ung. hydrg.*) and powdered opium is applied, which either checks it in the start or converts it into an insignificant affair, soon maturing.

It has been recommended to introduce into the boil, in its early stage, an injection of carbolic acid. This has been successful but is quite painful. Cocaine has been suggested, but the same objection holds. A strong solution of hydrg. bichl. 1 to 100 applied to the pimple or pustule is more effectual and produces little pain. It acts in the same manner as the mercurial ointment, destroying the microbe. The injection does not always strike the nest.

In some cases a plaster of extract of belladonna, if far enough from the place not to affect the eyes, acts as well as the opium. The effect is to tranquillize the nerves and also to narcotize and prevent the propagation of the specific microbe.

My first case was a lady, past middle life, of rather broken down constitution, I found a crop of boils covering her back and shoulders, thirty or forty in number, from the size of a pea to that of a walnut. The pain and irritation was intense. She warned me not to give her an opiate, as that would only add to her suffering. Calling for some lard I mixed with it half an ounce of pulverized opium spread it on a cloth and applied it to the back. It soon produced relief. I left with directions if any signs of narcotism appeard to remove the plaster and wash the surface clean.

When I returned the next morning the patient was sitting up in an agreeable frame of mind, having enjoyed a pleasant night's rest and showing no signs of narcotic effect or sequela. On removing the dressing I found the surface whitened, and most of the boils open and suppurating. A linseed poultice was then applied and in a few days the patient was well. It seemed at the time a life-saving application.

Since then I have never met so large a number together but have put on the opium plaster on single ones many times with the same good results. To the boils recurring in the vicinity of one that has seen its course, apply the mercurial ointment. If they are scattered over the person use on them, if seen early enough, the unguentum hydrg., or the solution of the bichloricle, to abort them. If they have passed this point apply the opium plaster or the belladonna. If the system is in bad condition give constitutional treatment—mercury in small doses, tonics, iodides and sarsaparilla.

The carbuncle requires a more vigorous treatment. The crucial incision, if far advanced, and the ointment or wash of mercury. If in the early stage, apply opium mixed with the mercurial ointment. In either case when the opening comes use a syringe and wash out the cavity thoroughly with a mild bichloride solution or a strong one of carbolic acid.

The application of opium to an inflamed surface may be much more extended. It relieves the pain and prevents the spread of traumatic erysipelas. and is valuable in burns and extensive ulceration. A poultice or fomentation as commonly used is a germ disseminator and cultivator. For open sores apply a cirate of opium and a covering of absorbent cotton. Fomenta-

tions are useful in deep seated phlegmons but when near the surface apply the opium as a plaster or cerate.

Very little of the active principle is absorbed through the skin or from an inflamed surface, to affect the nerve centers. Its effect, however, over inflammation is remarkable. It is more than probable that to this probably may be attributed its influence in peritonitis. It not only quiets the brain but the nerves of sensation and prevents or checks inflammation. Opium is admissable in inflammations of any part except of the bronchi, with equally good effect.

RETAINED PLACENTA: EFFECTS OF ATMOSPHERIC PRESSURE.

Cavilan, of Durango, Mexico (*Arch. de Tocol. et de Gynéc.*, March, 1892), attributes retention of the placenta to atmospheric pressure. His father, in the course of a large practice, only met with one case in thirty-five years of true, adherent placenta. He maintains that all the morbid conditions which might cause adhesions, such as uterine inflammation and placental apoplexy, produce abortion before any firm adhesions could be established. The common so-called "adherent placenta" represents an effect of atmospheric pressure. The central part of the placenta is first detached, and thus between the uterus and the maternal aspect of the placenta a vacuum is formed, the placenta being in the mechanical condition of a cupping-glass. Its edges are firmly pressed against the uterus. Pulling on the cord simply encourages the development of the vacuum. Abuse of ergot does the same kind of harm. Credé's method of expression prevents or overcomes the vacuum. When the placenta is distinctly "adherent," the vacuum must be destroyed. Cavilan acts in the following manner. The midwife or assistant pulls the cord firmly, obstetrician steadies the fundus with the left hand and perforates the placenta, close to the cord, with the right fore and middle finger. As the uterine tissues are far tougher than the placental tissues there is no fear of perforating the uterus with the fingers. The air then enters the vacuum and the placenta can easily be detached. The strongest antiseptic precautions are necessary during this manœuvre.—*Brit. Med. Jour.*

Hospital Reports.

BRAINARD MEDICAL SOCIETY OF WISCONSIN.

This Society recently met in Chicago, and devoted part of its session to attending the following clinics at Rush Medical College:

CLINIC ON PRACTICE.

Prof. Henry M. Lyman, speaking on massage, explained that it was not, as was so generally believed, a process of rubbing, but rather manipulation, and to better illustrate this had a patient brought to the amphitheatre to be massaged by a professional masseur. The professor explained that massage should always be commenced at the extremities, working toward the body, care being taken that every part of the limb be treated.

The Professor lauded its action in inducing contraction of the arterioles and thus accelerating the circulation, improving the nutrition of the parts, stimulating absorption and increasing secretion from the various organs.

It is in patients run down by pressure of business, etc., that we often prescribe travel, and this in patients who can afford the time and money is very well; but Doctors should not prescribe things that cannot be done, and it is in these cases that massage came as a boon, as it could be afforded by every one; it required but an hour every other day to get its benefits. It was wonderful how these patients, run down and exhausted, picked up, their appetites increasing, insomnia disappearing and the general circulation improving even after using it only for a short time. In continuation of the clinic a number of cases were brought in suffering from central nerve lesions. Two children suffering from the effects of poliomyelitis, one little girl, about 13 years old, suffering from mobile spasm or athetosis, and a little boy suffering from epilepsy, with attacks of mania following the epileptic attacks.

The histories of the cases of poliomyelitis were read by Dr. Cleveland which were similar to all these cases, the one lower extremity in each of the children was atrophied and shortened. The girl with athetosis gave no history of injury or prior disease of the brain or its envelopes. The

spasm of fingers and hand were very characteristic. In speaking of the seat of the trouble in these two groups of cases the Professor explained that in the cases of poliomyelitis, the lesion would be found in the cord, while in the case of mobile spasm it would be found in the brain, either in the thalamus, the lenticular nucleus, or somewhere in the gray matter of the pyramidal tract.

In the former cases judicious treatment should be followed by improvement, while in the latter, treatment on account of the nature and seat of the lesion, precludes their removal by remedial agencies.

The case of epilepsy was rather rare on account of the maniacal attacks following the epileptic attacks, as in most cases they precede the same. The patient kicks and bites and would destroy anything that happened to be in reach during these attacks, although perfectly harmless at other times. He has a history of insanity, as his father is insane. The Professor explained how these patients might become criminals, committing even homicide during these attacks, and yet be perfectly unconscious of the fact.

Some such patients would travel to a distance behaving well and having an attack of epilepsy return to consciousness, perfectly unaware of the just preceding acts, this might even lead to a dual life of the individual.

SURGICAL CLINIC BY PROF. N. SENN.

Prof. Senn in his clinic presented a number of cases, that had been operated on the last few weeks.

The first case to which attention was called was a laparotomy for the purpose of removing a fœtus in the free abdominal cavity. It had been there dead for some years. The fœtus at the time of death must have been about seven months old. In making the operation the placenta was found to be nearly absorbed, and what remained was therefore not removed, trusting that the remaining part would be absorbed, as the absorbing power of the parts would be increased by the removal of the fœtus.

The patient and the fœtus were shown; the patient had made an uninterrupted recovery, temperature normal after first day. The Professor thought that not withstanding Tait, he thought this case showed that the embryo could and did develop in the free abdominal cavity, as no symptoms of rupture could be elicited.

A case was next shown in which an operation for a large ventral hernia had been made with splendid success, the cicatrix being perfectly firm, and yet the Professor would advise her to wear a pad for some weeks as these cicatrices were always treacherous.

The next case was one that had suffered from pyelonephrosis and had been operated upon some weeks ago. The interesting part in the case was the large size of the stone that was found perfectly impacted in the pelvis of the kidneys, so that it was with great difficulty removed. The Professor laid great stress on his advice not to crush or break up such a stone, but to remove it whole even if the tissues should receive a little more injury, as through crushing, the liability of leaving pieces of the stone is great, which would merely serve as a nucleus for a return of the whole trouble.

The next case shown was one of nephrectomy that had been performed some time ago. In this case the occlusion of the ureter had dated back eleven years, it was therefore reasonable to suppose that the kidney structure had all disappeared, and on removing the kidney, it was found to be atrophied to the thickness of cardboard, perfectly translucent and yet Professor Senn was surprised to find on microscopical examination healthy kidney structure atrophied to be sure, greatly atrophied, but still perfectly normal structure. (Sections under the microscope were shown.) The Professor emphasized that here was a case of eleven years standing, a perfectly translucent kidney, and yet healthy structure, and it was important to save every particle of healthy kidney for your patient, nephrectomy never being justifiable as a primary operation if their be reason to believe there is any healthy kidney structure to be sacrificed. The following case of pyelonephrosis was diagnosed and operated on:

Young man, large tumor of abdomen, prominent on left side, fluctuating and most prominent between crest of ilium and lower border of rib, left side. The diagnosis of nephritic abscess was made and to verify its being a retroperitoneal tumor the hydrogen gas test was made. As the gas filled the colon, which was readily shown

by percussion, the tumor receded or rather the colon covering the tumor, the dullness disappearing and resonance taking its place. This proved that the tumor was retroperitoneal. The patient being anæsthetized, Professor Senn operated as follows: placing the patient on his right side, with a large round cushion under his right loin; this is important as it gives prominence to the opposite side and widens the space between the crest of the ilium and the last rib. Simons' incision was made and after reaching the tumor, an exploring needle was passed into it and pus withdrawn; the needle being left as a guide, the Paquelin cautery was used to make an opening through the kidney structure, a large amount of pus escaped, the tumor entirely disappearing. A thorough search was made for stone or other foreign body, but nothing was found. After a thorough washing out of the abscess a large double drain was introduced and the wound dressed with iodoform gauze packing, etc.

The Professor emphasized his advice to use large drainage tubes in these cases, so that the cavity of pelvis of the kidney could be seen and its condition noted, this being of great importance as we could then be certain that when the drainage tubes were removed, that the pelvis of the kidney was in an absolutely healthy condition because the parts could be actually seen and their condition noted before such removal. The Professor here also made a special mention of the value of peroxide of hydrogen for cleansing these and all similar abscess cavities and drew attention to its special use in these cases as by it the permeability of the ureter could be demonstrated.

CLINIC ON SKIN DISEASES BY PROF. HYDE.

The following cases were presented: A case of tinea sycosis, in which attention was drawn to its superficial resemblance to epithelioma. The next cases shown of tinea favosa, four in number, and they well illustrated the various phases of the disease. The one showing the smooth, shiny, parchment-like membrane of cicatrization and atrophy of a long standing case, the whole of the scalp being in this condition. The patient had received no treatment. The second case showed the same condition on a small patch, the patient having had treatment, the disease was stopped in its progress.

The other two cases showed the characteristic patches with irregular outline, festooned like, the lustreless dull stubs of hair, the yellowish greenish hue. As to treatment Professor Hyde used corrosive sublimate solution, carbolic acid and iodine, chrysarobine ointment, but would like to add that it will be a tedious cure, which will try the patience of both physician and patient.

The Professor had the group photographed, as it was rare to be able to get together four cases at one time at one clinic.

A case of *psoriasis* was shown with characteristic appearance. The Professor said that the variety we see here in this country is mostly due to the peculiarity of our spring and about the only treatment necessary is to wait for warm weather when the psoriasis will disappear, to return the following spring.

A case of *pityriasis versicolor* was shown, illustrating beautifully this disease.

The last case shown was one of *lupus vulgaris* of the face. The Professor in showing the case drew especial attention to the appearance of the patient, when the face was seen in profile, when as in this case the nose was attacked, in differentiating from syphilitic destruction. In the latter the nose was brought down in the middle, the tip rising, the nose becoming flat, while in lupus the nose, one might say melts away, producing as in this case, the typical parrot-peak expression. The Professor did not believe in the surgical treatment of lupus of the face; the best result he has had from the local injection of creosote.

EVENING SESSION.

At the evening session of the society the following cases were reported by the members:

Dr. P. O'Keef, of Oconto, Wisconsin, reported a case of laparotomy for ovarian tumor, attached to the fallopian tubes, size of large orange, cystic. After removing this and examining abdomen found another tumor on the right side, which proved to be a hæmatocele. Drainage tubes were used. Temperature never rose above 99°F. She had had a severe attack of pain in abdomen in December and the

hæmatocele undoubtedly dated from this time.

Dr. E. J. Smith reported the following cases:

A case of strangulated hernia of five days' standing.

The strangulation took place on Feb. 18th, the Dr. being called on the 23rd. for the first time. Considering the length of time that had elapsed since the beginning of the strangulation, the Doctor advised an operation at once without attempting reduction.

On reaching the intestine he found the same gangrenous, so that about two inches had to be resected. Circular enterorrhaphy was performed; the continuous Lembert suture was used. Silk was the suture material. The sac was dissected out, no drainage was used. Local anæsthesia by the use of cocaine injection was used. The Doctor in making the injection enters the needle only at one point, pushing it along under the skin its full length, in the direction of the proposed incision, then injecting as the needle is withdrawn, not allowing the needle however to escape from the skin, it is reversed and again pushed its full length under the skin in the opposite direction, and again the injection is made while withdrawing the same. The patients complain of no pain during the operation.

The case made a complete recovery, only two dressings being required. The Doctor then reported a case of operation for gall-stone in which the gall-bladder was opened and 142 gall-stones removed; there had been an attack of peritonitis some time before, and at the time of operation, the peritoneum was adherent to gall-bladder. This case also made a good recovery.

Wm. Hausmann,
Secretary.

Elmore, Wis.

MALE FERN TOXICITY.

It has been demonstrated by Quirll and Poulsson that oleoresin of male fern may develop its toxic properties when combined with or followed by castor oil, this being due to the solubility of the active constituents in oil, whereby absorbtion is favored. To avoid accidents, it is hence recommended to employ with this tænicide some cathartic other than castor oil.

Selected Formulæ.

The best general pill excipient I ever saw or used is made as follows:

℞ Powdered slippery elm.....2 drams.
Flour.....1 dram.
Glycerin.....2 drams.
Water.....4 drams.

Boil until thick paste is formed and be careful not to burn it.

—*F. P. Brigham, Jeffersonville, Indiana, in Meyer Brothers' Druggist.*

SICK HEADACHE.

For a long time I have searched for a prescription that would cure sick headache. Various combinations were tried, but nothing satisfied me until I came across the following in an English work on "Headaches; their Nature, Causes and Treatment," by Wm. Henry Day, M. D. To this I have added one ingredient, the bromide of ammonium. Some may object to the formula on the ground of polypharmacy, but where every drug is given for a definite purpose it is allowable to combine many ingredients into one prescription, especially when the resulting compound is as efficacious as the following:

℞ Sodii bicarb.,
Bismuthi subcarb.,
Pulv. acaciæ.....āā..℥ j.
Spts. ammon. aromat.....℥ ij.
Ammonii bromidi.....℥ jss.
Syr. zingiberi.....℥ iij.
Aquæ dest., q. s.....℥ viij.

M. Sig.—℥ j as required.

—*Ex.*

ULCERATED CHILBLAINS.

Dr. Brogg (*Internat. klin. Rundschau*, No. 46, 1891) prescribes in ulcerated chilblains the following salve:

℞ Acid carbolic.....1 gram.
Unguent. plumb. } āā 20 grams.
Lanolin... }
Ol. amygdalar. dulc.....10 grams.
Ol. lavander.....gtts. xx.

Apply two or three times a day.

DIGITALIN IN CARDIAC DYSPNŒA.

℞ Digitalin (crystallized).....10 cgrams.
Glycerin (30° Be.).....33 cc.
Distilled water.....14 cc.
Alcohol (95 per cent.) to make....100 cc.

(50 drops of this solution represent 1 milligram of Digitalin.)

℞ Digitalin (crystallized)..... 0.02 gram.
Alcohol.....12 grams.
Glycerin.....12 grams.

(60 drops of this solution represent 1 milligram of Digitalin.)

FORMULA FOR THE TREATMENT OF BURNS.

According to *L'Union Médicale* for January 14, 1892, Nikowsky recommends the following treatment in burns:

℞ Tannic acid.....3 iiss.
Alcohol.....3 iiss.
Sulphuric ether.....3 iiss.

Sig.—Make a solution, and apply locally in cases of burns of the second or third degree. Wash the part with a solution of boric acid, puncture the blebs, and apply by means of a camel's-hair pencil the solution of tannic acid just named. Cover the part with cotton wadding.

PERMANENT SYRUP OF HYDRIODIC ACID.

℞ Iodide of potassium.....123 grains.
Tartaric acid.....112 grains.
Water.....½ fluid ounce.
Diluted alcohol.....1 fluid ounce.
Syrupy glucose.....¼ fluid ounce.
Syrup.....enough to make 16 fluid ounces.

Dissolve the iodide of potassium in ½ fluid ounce of water and the tartaric acid in ½ fluid ounce of dilute alcohol. Mix the two solutions in a vial, cork and shake it well, and then place it in ice water for about one-half hour; again shake it thoroughly and then pour the mixture upon a small white filter, and filter into a bottle containing 13¾ fluid ounces of syrup and ¼ fluid ounce of syrupy glucose. When the liquid has run through, wash the vial and filter with ½ fluid ounce of diluted alcohol, added in several portions. Then add enough syrup to make 16 fluid ounces.

This method is said to afford a clear, transparent and permanent syrup. Glucose is singularly well adapted for the preservation of all syrups of the iodides or bromides, as with its use the reduction of the compound is greatly retarded.—*J. W. England.*

ANTISEPTIC TREATMENT OF PROFUSE DIARRHŒAS.

Dr. Broughton (*Deutsche med. Wochenschrift*, No. 1, 1892) recommends the following formula:

℞ Salicylate of bismuth.....10 grams.
Sulpho-carbonate of zinc.....2 dgrams.
Lime water, Distilled water } āā 50 grams.
Tinct. benzoated opium.....20 grams.

A teaspoonful every two hours until the diarrhœa ceases.

EUA ANTISEPTIQUE DE PAGLIARI.

The *Bulletin de la société pharmaceutique du Nord*, gives the following formula for Pagliari's antiseptic:

℞ Alum.....100 parts.
Benzoic acid.....2 parts.
Tincture of benzoin.....10 parts.
Water.....888 parts.

Dissolve the alum in the water by the aid of heat, add the benzoic acid, and, finally, the tincture of benzoin. Agitate strongly, let cool, and filter. This makes an excellent toilet antiseptic and can be used as a styptic in mild hæmorrhages, etc.

NEW METHOD OF EXAMINATION OF THE DIGESTIVE ORGANS.

Dr. Sahli, of Berne (*Correspondenz. Bl. F. Schweitzer Aerzte*: No. 2, 1891), has adopted the following ingenious procedure for determining the condition of the digestive functions: A pill containing about three grains of iodide of potassium is enclosed in a round sheet of very thin gutta-percha paper, the free margins of which are twisted in form of a bag and then fastened by a firm moist cord of fibrine, about one-eighth inch thick. The ends of the cord are brought together by a thread. The rubber sheet should be well covered with talcum, so as to prevent adhesion of the opposed surfaces. To protect the bag during swallowing, it is enclosed in a gelatine capsule. The author's object was to determine the time required for the iodide of potassium reaction to manifest itself in the saliva under various physiological and pathological conditions, this depending upon the rapidity with which the fibrine cord was digested and the iodide set free from its envelope. It has been stated that the manifestation of the iodide of potassium reaction depended upon the quantity of free hydrochloric acid in the stomach, but Sahli's experiments tend to show that the quantity of contained acid exerts less influence than has been thought. In like manner the administration of soda and pancreatic ferments in cases of deficient acid production, for the purpose of initiating intestinal digestion in the stomach, had no effect in accelerating the appearance of the reaction, and sometimes even delayed it. The reason of this was found to be that the acid and pepsin, or the pancreatic ferments, remained for too short a time in the stomach to exert any digestive action, being partly absorbed and partly passed into the intestines.

The value of this method in demonstrating the condition of the digestive functions is shown by some experiments made by Dr. Henne regarding the influence of pepper on stomach digestion. He found by chemical examination of the gastric juice that pepper administered in doses of 2½ grammes before meals had no essential effect upon the gastric functions, but that the iodide reaction appeared earlier if no pepper was given. Owing to the laxative effects of pepper, as demonstrated by these experiments, it is probable that it exerts a favorable effect upon intestinal digestion.

THE

MEDICAL and SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

DIRECT COMMUNICATIONS TO

P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor.
(Professor of Physiology, University of Penna.)

BUSINESS OFFICES:
29 to 35 North Tenth Street, Cor. Filbert.

EDITORIAL OFFICE:
Southeast Cor. 36th and Woodland Ave.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00

REMITTANCES should be made payable to THE MEDICAL AND SURGICAL REPORTER, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

—o—

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates).... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt **"The Medical and Surgical Reporter"** and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts.....$1.50 each.
Bovine Points or Quills..... 1.00 a doz.

Leading Articles.

THE TREATMENT OF ULCERS OF THE LEG.

The therapeutics of ulcers and varicose veins of the lower extremities may fittingly be considered together, because in hospital practice, at least, a very large proportion of leg ulcers are directly or indirectly due to over distension of the veins of the part.

Although this affection is a very common one, it is a fact that too often its treatment lacks the care and precision with which other surgical procedures are carried out. Of all the various forms of leg ulcers the varicose ulcer is certainly the most chronic as well as the most common. Since the pathology of these ulcers has been better understood, together with the conditions necessary for their reparation, more rational treatment has undoubtedly been pursued by the great mass of the profession. The importance of rest, position and pressure has been generally realized, and the means by which these ends have been sought particularly comprise nearly all of the modern modes of treating them. While certain modifications of treatment are almost universally advised in the different varieties of leg ulcers, in general terms the condition of the ulcer itself is the only practical guide to a rational, local therapeusis. Consequently, it matters little regarding local treatment whether an ulcer belongs to one or another of the classes ordinarily seen, viz: simple, varicose, syphilitic, tubercular, epitheliomatous, traumatic, etc.

The diagnosis of leg ulcers usually is a very simple mental process. Sometimes, however, it it very difficult to decide as to the real nature of certain forms of ulceration. In doubtful cases which have resisted thoroughly applied local and general measures it is always wise to call in consultation a well-qualified specialist upon skin diseases, and often it will be found that some important ætiological factor has

been overlooked, or that the specialist will distinguish the obscure and intractable lesion as belonging to a class in which amputation may be the only resort, viz: in bad cases of malignant ulceration. In this connection it should be borne in mind that long standing cases of simple ulceration may rapidly become malignant.

At a recent meeting of the Philadelphia County Med. Society, Dr. Thomas S. K. Morton read a very interesting paper upon the treatment of leg ulcers, in which he claimed many advantages for the mode of treatment pursued by him at the Philadelphia Polyclinic. His results have been so good that it will be of value to note his method. This consists in washing the ulcerated area thoroughly with soap and water, then with 1:1000 bichloride solution; the surrounding parts are shaved if this seems necessary to secure cleanliness. If no septic conditions are present in or around the ulcer the bichloride is omitted. Next, the ulcer and one inch of the surrounding healthy skin are covered by overlapping half inch strips of "Lister protective," over which moist bichloride gauze is evenly placed and the dressing completed by a bandage. The bandage is perhaps the most important part of this treatment, and consists of figure-of-eight turns around the calf, without reverses—the precaution in applying it being to keep the two edges of the bandage equally tense. Dr. Morton has used this bandage for the past five years, and he states that it will not only remain just as applied for days or even weeks and be absolutely comfortable to the wearer, but also permits the employment of the fixed antiseptic dressing while patients pursue their usual occupations almost unconscious that their former disabling disease is still present. This dressing is reapplied every day until the parts become odorless, free from all irritation and aseptic. Subsequently it is renewed every second day if the patient is actively working. By this simple form of treatment assisted by the application of silver nitrate solutions, scarification, occasionally skin grafting and applications of pepsin to large sloughs when these measures seem indicated, Dr. Morton claims that the time required to heal is usually incredibly short.

The method of treating this class of ulcers which has just been detailed can be employed with great advantage among the poorer classes, and its adaptability for such cases is at once apparent.

When varicose veins constitute the active cause of the ulceration, it becomes a question of how the vessels can best be supported. A firm, even bandage is after all the supporter *par excellence* and is usually effective in all mild or moderately severe cases. Where, however, the varices involve the greater portion of the limb, excision of the enlarged veins is the best remedy for the ulcers present. A very good remedy for varicose veins, according to Morton, is an ointment of ichthyol and lanoline (1:4) spread upon lint and applied to the limb by the same bandage which he ordinarily employs in dressing.

SYPHILIS OF THE PHARYNGEAL AND PRE-EPIGLOTTIC TONSILS

Drs. Moure and Raulin. (*Rev. de Larynx. Ot. et Rhin.*, No. 6-7, 1891.) make a contribution to the study of the manifestations of syphilis upon what have been described as the third and fourth tonsils, or in other words in the adenoid tissue in the vault of nasopharynx and in the follicles of the buccal pharynx at the base of the tongue.

The lesions, it would appear, are identical with those which occur upon tonsils proper, but their study has been neglected. When present they may cause modifications in deglutition, phonation and respiration, and may point to the seat of trouble in ear complications where nothing is taught by a superficial examination of the back of the mouth and throat. Dr. Labit thinks the abuse of alcohol and of tobacco influences not only the development of these lesions but their duration.

Book Reviews.

THE SCIENCE AND ART OF MIDWIFERY. By William Thompson Lusk, A. M., M. D. Professor of Obstetrics and Diseases of Women and Children in the Bellevue Hospital Medical College Fourth edition, revised and enlarged. New York: D. Appleton & Co., 1891.

The rapid strides of progress in midwifery and gynæcology are nowhere better illustrated than by a casual glance at the successive editions of the text-books on these subjects. The greatest advances will be noticed to have occurred in those directions in which modern surgery has cleared away many formerly insurmountable obstacles from the pathway of the practitioner in these branches.

In comparing the present edition of this work with its predecessor, we observe such vital differences, according to our modern thoughts, that for all intents and purposes the book before us is almost wholly new, only retaining the literary style and arrangement to mark its relationship to the volume of a few years ago. The development which has occured in the theory and practise of midwifery has been due to the pains-taking efforts which have more recently been in vogue to reduce our knowledge of the anatomy and pathology of the pelvis and its organs to exactness of expression and record. The studies in the normal and pathological anatomy of the pelvis have largely contributed to modify the theories and accepted mechanism of labor. The revelations concerning antiseptics and asepsis have largely modified and restricted many of the formerly very common diseases following labor, and their application to surgical practise has made it possible to obtain results which the most sanguine observer of but seven years ago could have conceived scarcely.

From what has been said it will be apparent that it is impossible in our limited space to minutely compare the author's present volume with the edition of 1885. The changes in theory and practice have so radically destroyed many deductions of that period that comparison is impossible.

Many portions of the work have been entirely rewritten. No effort has been spared apparently to present the best obstetrical teachings of the day. The chapters on the mechanism of labor have been most carefully revised. The chapter upon diseases of the decidua is well worth reading. Extra-uterine pregnancy is excellently presented, and the treatment is wholly in accord with the advances which have been made in surgery. Abdominal palpation and pelvimetry receive careful consideration. The instruments used in the latter are carefully described. The subject of puerperal fever is presented with the modern views and compared with former ones. The same may be said of eclampsia. The last chapter of the work contains a well-written, short description of puerperal insanity. The author states that fully sixty per cent. of cases end in recovery. This estimate is lower than that of Bevin Lewis, who has quite recently written a masterly treatise upon diseases of the mind. In the space allotted to puerperal fever there are five very well executed colored prints of microscopic sections of puerperal endometritis, which show plainly streptococci pyogenes, staphylococci aurei, and other forms of disease germs.

The book is very creditably printed and bound, contains 761 pages, 32 chapters, and is illustrated by 232 illustrations and 4 handsomely engraved plates taken from nature. It is a very complete treatise for student or practitioner, and we can unhesitatingly say that it leaves very little to be desired as a modern reference book. The index in by no means an insignificant feature, and adds greatly to its usefulness.

CHANGES IN THE CEREBELLUM AS THE RESULT OF CEREBRAL HYDROCEPHALUS.

Chiari differentiates three types, which are illustrated by exhaustive clinical histories and pathological descriptions, too long for reproduction. As the first type, he describes a drawing out of the cerebellar tonsils and the median part of the inferior lobes into processes which accompany the medulla into the cervical canal. The second type includes the dislocation of parts of the cerebellum into the dilated fourth ventricle, which is prolonged into the expanded cervical canal. As an instance of the third and severest type he relates a case, supposed to be of hydromyelocele cervicalis, in which the sac and contents were removed. Autopsy showed that almost the entire cerebellum, expanded into a cyst, had been removed.—*Deutsche Med. Wochensch.*, No. 42, 1891.

Periscope.

THERAPEUTICS.

TEUCRIUM SCORDIUM IN PRURITUS ANI.

Dr. Brinton (*Wiener med. Presse*, No. 17, 1892) recommends the use of teucrium scordium in pruritus ani. In obstinate pruritus ani from hæmorrhoids or when there is no local lesion, he employs the powdered leaves with success, in doses of five to six decigrammes (eight to ten grains three times a day, half an hour before meals. After they have been used for seven to ten days the pruritus gradually disappears entirely. When the hæmorrhoids, are well developed the results is no so good; from this it is seen that the remedy acts chiefly upon the nervous cause of the pruritus.

THE TREATMENT OF TETANUS.

Rènon (*Ann. de l' Inst. Pasteur*, April, 1892) reports two cases of tetanus treated by the method of Behring and Kitasato. Although both terminated fatally, they afforded some useful indications, particularly regarding the dose of serum which should be employed. Behring and Kitasato discovered that the serum of the blood of animals immunized against tetanus exerted a powerful antitoxic action upon the tetanic poison; they showed that susceptible animals resisted the inoculation of quantities of tetanus cultures several hundred times greater than the lethal dose if the animals were injected at the same time, or some time after, with a little of the blood serum of an artificially immunized animal. Rènon compares his two cases with four recorded by Tizzoni, all of which were successful, and with one of Baginsky and Kitasato which was unsuccessful. In Rènon's own cases the duration of the disease was, in one seven, and in the other, eight, days; in the case of Baginsky and Kitasato the duration was eight days. On the other hand, in two of Tizzoni's successful cases the treatment was only commenced about twelve days after the onset of the disease. From these facts Rènon is inclined to believe that Tizzoni's results were in some degree due to the fact that his cases were of a milder type and of slower progress. He does not consider that the want of success in these cases affords any valid objection to the application of the treatment to cases of tetanus in man: but he points out that it should be commenced as soon as possible, and that possibly larger doses of the serum may be required. He observed no ill-effects from the treatment; on the contrary, each injection was followed by marked, but unfortunately, only temporary relief.—*Brit. Med. Jour.*

ARISTOL IN CHRONIC DYSENTERY.

Dr. Randall (*Med. Neuigkeiten*, No. 17, 1892) has treated three cases of chronic dysentery with aristol with excellent results. The most serious case was that of a sixty-year-old man, who had for six months suffered from chronic diarrhœa, and for the last six weeks had been obliged to keep his bed. The localization of the pains pointed to the lower portion of the tranverse colon being involved in the ulcerating process. A suppository of two and a half grains of aristol and one-third of a grain of morphine was ordered to be inserted three times a day. Two days later the stools became less tepid, more consistent and free from blood. Within a week the painfulness disappeared, and only one more hæmorrhage appeared. The stools, which had been very painful and of hourly occurrence, were reduced to six or eight per diem; they were soft, but not thin, and nearly free from epithelial debris. In ten or twelve days all traces of rectal ulceration had disappeared. Then only one grain was given per diem, and morphine in the evening. In a short time he was on the road to recovery.

ERGOTININE.

In *La Médecine Hypodermique* 1892, No. 2, p. 17, Dr. Franck recommends the use of this active principle of ergot in place of ergotine, which is frequently inert and often untrustworthy. It is prompt, surer, and more constant, does not give rise to local accidents, and is useful in smaller dose—$\frac{1}{250}$ to $\frac{1}{120}$ of a grain. Nor, indeed are these injections painful. Evetsky and Denslow have used it in acne. Alternating with hypodermatic injections of iron, it is useful in the menstrual disturbances of young girls. It has been used with good results in several cases of cerebral apoplexy, epistaxis, hæmoptysis, hæmaturia, hæmatemesis, and purpura

hæmorrhagica. Haning has used it in suppository in hæmorrhoids, and it is valuable used hypodermatically in this same condition when injected into the margin of the anus. Dujardin-Beaumetz has treated with success menorrhagias, Ducros has employed it for paralysis, and Payan for paraplegias. In lead-paralysis Hiter has obtained a cure in less than a month, giving also iodide of potassium. Payan, Allier, and Guersant, Jr., have treated paralysis of rectum and bladder, especially in old subjects, by this remedy.—*Amer. Jour. Med. Sci.*

RESORCIN IN GASTRIC ULCERS.

Pope uses resorcin in a dose of five grains three times a day in cases of gastric ulcer. It is both antiseptic, analgesic and hæmostatic. Its analgesic property being the most valuable, enabling the stomach to tolerate food. He has also given it with advantage in gastric cancer.

TREATMENT OF APPENDICITIS.

At a meeting of the Paris Surgical Society on May 25th, 1892 (*Sem. Méd.*, June 1st, 1892) Jalaguier showed two cases of appendicitis which had been cured by operation. The first was a strong boy, aged 14½, who had had the vermiform appendix removed on account of recurrent attacks of appendicitis. The second was a child, aged 10½, who, after two previous slight attacks of appendicitis, was admitted on March 24th, 1892, to the Hospital Trousseau, presenting the following symptoms, namely, abdomen very tender, especially in the left iliac fossa, considerable distension, frequent vomiting, and pinched expression of face. The temperature was 38.5° C., the pulse 120. A median laparotomy was at once done, and the peritoneal cavity opened. The intestines were seen to be covered with a layer of fibrous lymph, and to be bathed in pus. Collections of pus were also found in the iliac fossa, in the pelvis, and between the omentum and coils of intestine. A considerable collection of pus was also found behind the cæcum; the pus in this part had a fœtid odor, and on washing out the cæcal region a ball of fæces as large as a pea and of the consistence of mastick was removed. The abdomen was then thoroughly washed out with boric solution, and five large tubes inserted for drainage; two were placed in the pelvis, two behind the cæcum, and one in the left iliac fossa. Several strips of salol gauze were also packed over the intestinal coils. The upper three-fourths of the wound were closed with sutures, and a dressing of salol gauze applied. The child bore the operation, which lasted twenty-nine minutes, well; vomiting did not occur, and the bowels were open during the night. Recovery soon took place; the strips of gauze were removed on the sixth day, the drainage tubes reduced to one on the tenth day and discontinued on the fifteenth day. On May 14th the child was discharged well.—*Brit. Med. Jour.*

PIPERAZINE.

Drs. Biesenthal and Schmidt review, in the *Berliner Klinische Wochenschrift*, January 11, 1892, the clinical reports on piperazine which have appeared recently. The reports of Vogt, Ebstein, Heuback, Krakauer, and Brik (see *Therapeutic Gazette*, February, 1892, p. 114) are all very favorable. Testimony seems to be nearly unanimous that the remedy is harmless and that it is effective as a solvent of uric acid.

Biesenthal and Schmidt report seven cases in which the remedy has been tried. Four of the cases are given in detail. In three of the latter, who were gouty patients, and had attacks of gout, marked relief was obtained. The fourth patient had violent attacks of renal colic. On the first day the piperazine was used, an extraordinary quantity of gravel was passed. After the second dose, on the next day, large quantities of gravel were passed several times, and almost immediate relief was experienced. Similar results were obtained in other cases. Biesenthal and Schmidt recommend the remedy very highly.

Internally, they say, piperazine is best given in dilute solution in doses of fifteen grains distributed during the day. Its taste is very slight. As it is not irritating to mucous membranes, a one or two per cent. solution may be employed in washing out the bladder in the case of vesical calculi. Hypodermic injections into gouty deposits and local applications to gouty swellings may also be employed.

THE TREATMENT OF INEBRIETY.

Dr. Charles L. Dana has made a very careful study of 614 male alcoholics treated at Bellevue Hospital. He believes that strychnine has a certain degree of specific effect in inebriety, and in alcoholic intoxication. In acute alcoholism, when the system is overwhelmed with the poison, one-sixtieth of a grain every two or three hours; in the chronic form, it should be administered in good doses for a considerable time. In ordinary acute delirium of alcoholism, twenty to forty grains of chloral, repeated in smaller doses in two or three hours, and combined with digitalis and strychnine, is the safest and surest means of controlling the excitement and securing sleep. A preliminary lexative, and a careful diet of hot milk and beef-tea with red pepper, should be insisted upon. In febrile delirium tremens, depressants must be used with care; cold baths or cold wet-packs, with friction, must be applied every two or three hours while the temperature remains high. Hypodermic injections of morphine are rarely needed, and he does not advise them.—*New York Medical Record*, 1892, No. 1115, p. 309.

PUMPKIN SEED IN THE TREATMENT OF TAPEWORM.

Dr. H. Roemer (*Pharmaceutische Presse*, No. 15, 1892), recommends the peeled seeds of the common pumpkin as an effective and safely acting tæniafuge. For an adult the dose may be placed at sixty or seventy grammes (two to two and a half ounces) of the peeled seeds. Half the quantity of oilless cocoa is added, with a little sugar and some syrup, and water enough to make a plastic mass on rubbing it in a mortar. This is made into fifteen or twenty pastiles and coated with sugar. The patient, after the usual preliminary period of fasting and a dose of castor oil, is given one of the pastiles every ten minutes. Children require but half this quantity. The result is astonishingly good. The writer has expelled over one hundred tapeworms in this manner. Only in a few cases was vomiting noticed. In general, the patient feels no disagreeable symptoms.

The seeds of the last year should be used and carefully peeled, which will be found a tedious task. Whether the oil is the active principle, or whether it is first developed by the crushing of the seed with water, as is the case with bitter almonds, mustard, etc., the writer does not attempt to solve.

TRICHLORIDE OF IODINE IN OPHTHALMOLOGICAL PRACTICE.

At the Ophthalmological Congress recently held in Paris, Pflüger (*Sem. Méd.*, May 4th, 1892) spoke strongly in favor of trichlorine of iodine as an antiseptic in various affections of the eye. He recommends a 1 in 5,000 solution for ordinary cases, and solutions of 1 in 2,000 or 1 in 1,000 when an energetic antiseptic is required, as in infectious lesions of the eye, whether superficial or deep. In commencing panophthalmitis, he uses a 1 in 1,000 solution.

THE TECHNIQUE OF INTERSTITIAL IODINE INJECTIONS IN THE TREATMENT OF GOITRE.

Dr. Duguet has used this method since 1874 (*Journal de Médecine*, 1892, 4e. cahier, p. 129). He concludes that the recent fleshy goitres, occurring ordinarily in young subjects, are the ones which disappear most easily and rapidly; the recent cystic goitres are still more rapidly cured; the goitres of long standing—in general, hard, fibrous, calcareous, sometimes aneurismal—result often very favorably, at other times less satisfactorily. The solution used is one part of iodine to twelve of 90° alcohol, injected with a hard-rubber Pravaz syringe carrying a steel needle, the latter to be cleansed after each time of using with a weak solution of ammonia. In the intervals the syringe and needles are kept in a ten per cent. solution of carbolized oil. The injection is made deeply into the tumor, but only when, after making the puncture, blood does not flow during the ensuing several seconds. The injection is made slowly, watching the patient's face. For checking the cough which may be produced by the injection, after taking out the needle, the patient takes several swallows of wine. These injections are repeated at intervals of eight or fifteen days, but not during menstruation, nor in patients who suffer from albuminuria. The amount injected is seven to fifteen drops.—*Amer. Jour. Med. Sci.*

STROPHANTHUS IN EXOPHTHALMIC GOITRE.

Dr. Fergusson (*Medical Standard*) claims good results from strophanthus in exophthalmic goitre. In nine cases the almost immediate disappearance of cardiac symptoms permitted patients to resume their occupations. The pulse fell from 150 and over to between 85 and 75, and there was a diminution in the exophthalmia, and in the thyroid gland to a fibrous condition, the result of the great duration of the disorder. Fergussion recommends eight to ten drops of the tincture thrice daily. In some cases he has given as much as twenty to twenty-five drops as a dose. Small doses have no effect whatever.

MIGRAINE.

This was the subject of a clinical lecture by Dr. G. M. Hammond. Migraine usually first makes its appearance at about the age of puberty, though it may develop earlier. Angio-spastic migraine is supposed to be due to a spasm of the blood-vessels on the affected side as a result of irritation of the cervical sympathetic. Whether the vascular spasm is a simple accompaniment of the disease, or its approximate cause, has not yet been determined, but in the author's experience remedies which dilate the blood-vessels give relief, while those which contract the blood-vessels increase the pain. In treating this form, inhalations of nitrite of amyl and internal administration of glonoin in doses of 1-100 of a grain, alcohol in moderate quantities, quinine in doses of from 10 to 15 grains, or a hypodermic injection of $\frac{1}{80}$ or $\frac{1}{90}$ of a grain of strychnine, will usually stop the paroxysm. The author does not administer opium for this disease, owing to the liability of the habit being formed. In the general treatment for the disease sources of irritation should be removed; eye defects removed; constipation or indigestion should be removed, or any other condition that may be a contributory cause. Fowler's solution in five or six drop doses three times a day for several months is considered a favorable remedy. Iron, quinine, strychnine and the phosphates are also recommended. Another form of migraine is the angio-paralytic form. In this form the vascular condition is that of dilatation. For this the author recommends phenacetin in large doses, arsenic and the bromides.—*International Clinics*, Jan. 1892.

MEDICINE.

A CASE OF PROGRESSIVE GENERAL PARALYSIS OF VERY EARLY COMMENCEMENT.

Charcot and Dutil (*Archives de Neurologie*, March, 1892) state that the symptoms appeared at the unusually early age of 14, and the further development of the affection leaves practically no doubt as to the correctness of the diagnosis. All the essential symptoms were present, profound impairment of the intelligence, speech embarrassment, pupillary inequality with the Argyle-Robertson sign, trembling of the hands, congestive seizures and attacks of sensory epilepsy. This precocious or *juvenile* variety presents, the writers think, some peculiarities which distinguish it from the ordinary or normal type. Occurring most often at the critical period of puberty (14 to 16), psychical troubles are the first to appear, and one of the most marked features is an arrest of physical development. The mental condition is in the majority of cases one of tranquil debility, without excitement or ambitious delirium, and much resembles that occurring in the general paralysis of women. Its duration varies from two to five years. The chief factors in the ætiology are hereditary neuropathic predisposition and congenital syphilis.

RHEUMATOID ARTHRITIS.

Blake (*Provincial Medical Journal*, 1892, xi, 121, p. 11) expresses the view that a proportion of cases of rheumatoid arthritis are dependent upon some form of intoxication, in consequence of which the nervous system suffers secondarily. He therefore recommends that in a given case a careful search should be made for a source of poisoning from within or without. This found and removed, the circulation is to be supported, mental strain relieved, and nutrition maintained. Passive, motion and massage, conjoined with electricity, should be energetically employed.

MINERS' NYSTAGMUS.

While this is a subject in which our special interest is almost purely a scientific one, it is worth while to note in a few words a review in the *Oph. Rev.*, April, 1892, of a recently published monograph on the subject by Simeon Snell. After a careful study of the conditions under which the miners work, and the details of numerous cases of miners' nystagmus, he very positively attributes the affection to the excessive action of the ocular muscles demanded by the constrained position in which the miner works. While not denying some influence to insufficient illumination, he considers it as a factor of subordinate importance. He does not believe it due to central changes. These views are somewhat at variance with those of other competent observers, especially as regards the importance of illumination. Miners' nystagmus would seem to be due to a "continued effort to fix under conditions which render continued fixation, peculiarly difficult," and the importance of each factor must be determined in each case. Sometimes a change simply in the manner of work, and not in its nature, is sufficient to give relief to this distressing condition, and the volume in question gives many valuable points as to prevention and treatment.

INFECTIVE ENTERITIS.

Gaffky (*Deut. Med. Woch.*, April 7th, 1892) reports the cases of two laboratory assistants and their servant who were seized on the same day with an acute illness. The chief symptoms were sudden onset with shivering, fever, diarrhœa, delirium, and prostration. In one case there was also albuminuria, and in another hæmorrhages into the mucous membrane of the mouth. In the third case the disease was mild. The poison had evidently entered by the mouth. Some milk was the only common article of diet of which these patients had partaken on the previous day, and which had been brought into the laboratory. The author had been making experiments with the bacilli found in cases of meat and sausage poisoning, but he does not think the milk could have been infected in this way, as it had only been in the laboratory a short time. It was found out that in the dairy from which this milk was obtained one of the cows had suffered from diarrhœa, small blood clots being passed. The dejecta, examined with all precautions by Professor Winckler, showed a very small and active bacillus. The same micro-organism was found by the author in the patients' stools. In cultivation and inoculation experiments it behaved somewhat differently from the micro-organism of meat poisoning. The author thinks that it was a culture of the bacterium coli commune of exceptional virulence and rapid growth, but he adds that much caution is needed in such conclusions, because the constant presence of this bacterium, pathogenic to many animals, makes it difficult to recognize other possible causes of disease in the intestinal contents. A specimen of the milk examined showed only micrococci innocuous to guinea-pigs. But the poison might have got into the milk otherwise than by the way of the mammary gland itself, that is, by the contamination of the milk by the dejecta, and the author says that this fact is not sufficiently recognized in the transmission of infective disease, even such as tubercle, to man. The boiling of milk is still insufficiently adopted.—*Brit. Med. Jour.*

EXOPHTHALMIC GOITRE.

Möbius, in an exhaustive article on this disease, draws the following conclusions: Basedow's disease is probably due to changes in the function of the thyroid gland. To prove this he mentions: (1) The similarity between this disease and others which depend upon changes in the thyroid, namely, myxœdema and cretinism. (2) The fact that in some cases exophthalmic goitre is secondary to simple enlargement of the thyroid. (3) That operative treatment seems in some cases to either benefit or cure the disease.

We know little or nothing about the causes which bring on the primary changes in the thyroid gland. It is probable, however, that the action of some poison on the system is an important ætiological factor. Among predisposing causes are the female sex, neurotic inheritance, possibly climatic conditions and national peculiarities. Under favorable circumstances those conditions which diminish the resistance of the body, more especially of the nervous system, seem to act as exciting causes.—*Deutsche Zeitschrift f. Nervenheilkunde*, Nov., 1891.

THE EFFECTS OF INFLUENZA UPON THE MIDDLE EAR.

Sir William Dalby, in a clinical note published in the *Lancet* of 20th of February, stated that a person with healthy ears has little to dread from influenza so far as the mucous membrane of the middle ear is concerned, but that it may become a serious trouble to one whose ears have formerly been the seat of inflammation. A correspondence on the subject will be found in subsequent numbers of the *Lancet*, in which the various writers agreed with the latter portion of Sir William's statement, but took exception to the first part. Each, from his experience of cases of middle ear inflammation following influenza in those who previously had perfectly healthy ears, took exception to the conclusion that "those with healthy ears had little to dread."

THE PATHOLOGY OF PARALYSIS AGITANS.

Borgherini (*Revist. sper. di Freniatria e Med. leg.*, 1891, vol. xvii, fasc. 1, 2) has reported a case of paralysis agitans, in which after death, on careful microscopic examination, an excessive formation of connective tissue was found in various parts of the cerebro-spinal nervous system, with pigmentation and atrophy of gray matter and ganglion cells. The walls of the capillaries were thickened, the lumen of the vessels was increased, and the perivascular lymph spaces were dilated. In many places miliary aneurisms were present. The lesions are thus those of senile involution.—*La Médecine Moderne*, 1891, No. 43, p. 746.

HIP-JOINT DISEASE AND SOME NEW LATERAL TRACTION SPLINTS FOR ITS TREATMENT.

Phelps, (*Med. News*, 1891, lix., 725.) writes:—To conclude, my observations lead me to believe that one of the most serious elements of destruction in hip-joint disease is the trauma and pressure produced by muscular spasm; that fixation of the joint without extensions is an impossibility; that the successful treatment of the joint must depend upon its absolute immobilization, which can only be produced by proper extension and fixation; that the constitutional treatment of hip-joint disease amounts to but little, independently of mechanical treatment; that mechanics is everything; that extension in the line of the axis of the shaft and in the time of deformity alone in hip-joint disease is entirely wrong; that extension should be made in a line parallel to the axis of the neck, in other words, two lines of extension; that ankylosis is not produced by immobilization, but by the severity and character of the inflammation; that the long traction hip-splints in general use neither properly extend nor immobilize the joint; that in a large percentage of cases the intra-articular pressure results in the destruction of the joint or in ankylosis; that the results in hip-joint disease should be as good as those in knee-joint disease and will be, provided perfect immobilization can be maintained; that patient should never be allowed to step upon any positive apparatus; that a high shoe in the well leg, and crutch, should be insisted upon until the patient is cured; finally, that the angular deformity seen in cured cases should not occur —such cases are a standing rebuke to the splint and methods employed.

TABES DORSALIS.

In a recent lecture at the Salpetriere, P. Blocq (*Gaz. Hebd. dé Med. et de Chir.* March, 1892) stated that recent researches upon the morbid histology of tabes in its first stage show that the internal radicular fasciculus is invariably the primary seat of the pathological change. The fibres of this system are thick, develop at a period of fœtal life anterior to the seventh or eighth month, and are the conducting paths of the muscular sense. The other fibers of the posterior root—slender and not apparent until the fœtus is near maturity—are the media by which cutaneous impressions are transmitted. From an evolutionary standpoint the muscular sense is inferior to the cutaneous sensibility its subservient neural elements consequently are the more prone to the influence of hereditary defect. This latter, he further considers, is the main ætiological factor in tabes, though often an accidental exciting agent, such as syphilis, can be discovered. In Friedrich's disease the heredity alone determines the occurrence of a lesion which at first is identical in situation and nature with that of early tabes.—*Brit. Med. Jour.*

THE ROUTE OF RESPIRED AIR THROUGH THE NOSE.

Kayser (*Arch. of Otol.*, xx, 1) asserts that during inspiration in the normal nose the bulk of the air passes along the septum, above the inferior turbinated bone, describing a semicircle in its course, and extending upward nearly to the roof of the nose. The general opinion that the current of air passes through the *pars respiratoria* is erroneous. The division of the cavity of the nose into a *pars respiratoria* and a *pars olfactoria* is permissible anatomically, but not justifiable physiologically.

DIAPHRAGMATIC HERNIA.

Niemöller (*Berl. klin. Woch.*, April 11th, 1892) relates the following characteristic case. A man, aged 25, had complained for six months previous to admission of nausea, vomiting, and loss of strength. He was thought to be suffering from chronic gastric catarrh of alcoholic origin, and dilatation of the stomach. A swelling of doubtful nature, but thought to be possibly a misplaced organ, was felt in the umbilical region. In three months' time the patient died. At the necropsy a tumor was found in the thorax immediately above the diaphragm and to the left side, of the size of a man's fist. It communicated with the stomach, for pressure on the latter caused it to swell. By pulling on the stomach, the protrusion could not be reduced, owing to the adhesions. The communication was through the tendinous part of the diaphragm. The much dilated stomach was covered in great part in front by the gastro-colic ligament, and the colon also crossed it. The pylorus instead of lying to the right of and below the cardia, lay to the left above. The part of the stomach near the pylorus formed the hernia. The spleen was displaced backwards, and there were many peritoneal adhesions. After referring to the fact that the condition is mostly made out only after death, the author draws attention to the percussion note over that side of the chest. He says that the normal percussion note is replaced by a tympanitic one, and that the height to which this latter extends depends on the gaseous contents of the stomach or intestine. Treatment can mostly only be symptomatic. These herniæ are divided into the congenital and traumatic. In the above case the increased abdominal pressure brought about by the vomiting forced the viscus through the defect in the diaphragm. The displacement of the organs, and especially that of the pylorus, unless due to peritoneal adhesions, was difficult to explain.—*Brit. Med. Jour.*

GLYCOSURIC, OR TRUE TABES.

Drs. Guinon and Souques, (*Archives de Neurologie*, March, 1892), state that in a glycosuric case if the nervous symptoms be limited to loss of the reflexes, fulgurant pains and loss of objective sensation, true tabes may be suspected, but is not demonstrated beyond doubt. Results of antiglycosuric treatment may aid, but not render certain, the diagnosis, since Westphal's symptom in diabetic cases is the last to yield to treatment. If it yield to treatment the presumption is in favor of diabetic pseudo-tabes. If glycosuria result in an ataxic case, then the absence of polyuria, variability of the amount of sugar, and absence of polyphagia and polydipsia, are in favor of a tabetic origin, especially if anæsthesia, frequent pulse and laryngeal crisis be present. If these last symptoms be absent the chances are in favor of diabetes, especially if the usual symptoms of diabetes be present. Diabetes may, however, complicate locomotor ataxia.

TUBERCULOSIS OF THE IRIS.

For some reason not easy to explain the iris is sometimes the seat of a local tuberculous process, the recognition of which is a triumph of diagnostic art. As to the identity of the lesion, there is no room for doubt, and it is highly important to decide how the bacilli got there and what is the prognosis. Hitherto tuberculosis of the iris has been generally regarded as a form of local tuberculosis, and the eye is consequently removed to prevent constitutional infection. This is a grave proceeding, and acquires additional gravity from the arguments advanced by Prof. Leber in support of the iritic effection being only a secondary, and not, as usually supposed, a primary lesion. He points out that the bacilla can only reach such a structure as the iris by one channel, viz., the blood, and the presence of the bacilla in the blood implies the existence of a focus of infection elsewhere in the body, in the glands,

the lungs, etc. Obviously if this be the case, enucleation of the diseased eye would not be justifiable on constitutional grounds. On the other hand, some few cases have been recorded of recovery after removal without any subsequent tuberculous manifestation. This fact may be interpreted in two ways—either as an argument in favor of the "local" view or as a reason for doubting the validity of the diagnosis. The latter reposes exclusively on the bacteriological examination of the diseased tissue, and it must be confessed that the alleged discovery of "one or two characteristic bacilli" hardly carries conviction. Pending further knowledge on this subject, it is to be hoped that no one will remove eyes on the ground of tuberculosis of the iris unless and until its functional integrity has been hopelessly compromised. —*Med. Press.*

PARALYSIS AGITANS IN A YOUNG MAN.

Quintard (*Bull. de la Soc. de Med. d'Angers*) has reported the case of a youth, sixteen years old, who presented the symptoms of paralysis agitans. Two years previously, following exposure to cold, tremor appeared in the right hand and continued for a month; while within two months the tremor had reappeared, now extending to the arm and shoulder. Soon the characteristic movements also involved the lower extremity upon the same side.—*Journ. de Méd. et de Chir. Prat.*, 1892, lxiii, 5, p. 182.

SURGERY.

ON RESECTION OF THE LIVER, ESPECIALLY FOR HEPATIC TUMORS.

Keen (*Boston Medical and Surgical Journal*, April 28, 1892) gives the results of analysis of twenty cases of resection of the liver.

The ages of these cases varied from 21 to 58 years. In striking contrast to age, sex is evidently a potential factor. Of the nineteen cases in which this was given, sixteen were females. The author thinks this frequency has probably something to do with tight-lacing.

The tumors and portions of liver removed have varied in size from a small nut to three fists. Of the twenty cases nearly all were incorrectly diagnosed. In some few cases floating kidney was diagnosed, while in others tumor of the pancreas was supposed to exist. The tumors found were echinococcus and hydatid cysts, cancer, syphilis, sarcoma, and adenoma.

The author thinks, as a result of experiments on animals, a large portion of the liver can be removed without interfering with its function and without any unreasonable danger.

Ponfick found that even the removal of three-fourth of the liver could be recovered from, although the prostration was very severe at first. Von Meister relates that when the above amount is removed, within a space of thirty-six days, repair had advanced to such an extent that the original weight of the organ was regained.

The escape of bile in the peritoneal cavity is generally of no consequence.

In preventing hæmorrhage the base of the tumor is severed by repeated small touches of the cautery point, the large vessels all being ligated. The stump, in the majority of cases was returned to the abdominal cavity; while in six cases it was sutured in the abdominal wound.

Of the twenty cases seventeen recovered, two died and in one the result was unknown. The mortality thus far has only been ten per cent.—*Univ. Med. Mag.*

CONTRIBUTION TO THE TREATMENT OF EPIDIDYMITIS WITHOUT RESTRICTION OF EXERCISE, WITH A SKETCH OF A SIMPLE BANDAGE.

Philippson (*Theurapeutische Monatshefte*, April, 1892,) describes a new treatment of epididymitis which allows the patient perfect freedom to go about. The principles of his treatment are:

(1) Compression of the testicle, which causes the inflammatory swelling rapidly to disappear.

(2) Puncture of the tunica vaginalis. Sometimes compression alone is indicated, while in other cases puncture and compression may be necessary.

As a dressing iodide of lead plaster was first tried, but this had the disadvantage of producing excoriations. He then used suspensories. It was found difficult to get two alike, and they were rather difficult to adjust. One of two methods of compression, by means of bandages, may be used:

(1) Two flannel bandages, quite elastic, and two circles,—one of flannel, the other

of gutta-percha. One bandage first draws down the testicle from the inguinal canal. The two circles are then placed underneath the testicle and covered by succeeding turns.

This method often produces unbearable pain.

The author recommends the following:

(2) A flannel bandage, three metres long and three centimetres wide is used, the first turn being applied above the testicle. This end of the bandage he allows the patient to hold until the following circular turns are firm enough to hold it and prevent the testicle from slipping up towards the inguinal canal. The dressing is then completed by alternate circular and spiral turns of the bandage, and the two ends fastened together with a safety pin, and the whole surrounded with a suspensory bandage. This dressing may be reapplied daily.—*Univ. Med. Mag.*

INTUBATION FOR THE RELIEF OF STENOSIS OF TUBERCULAR LARYNGITIS.

Dr. F. E. Hopkins reports a case which was successful so far as the relief of the stenosis was concerned (*New York Medical Journal*, 1892, No. 691, p. 334). Massei has operated in three cases and Dillon Brown in one case, for the purpose of securing euthanasia. It seems likely that this operation, on account of ease and quickness, the comparative absence of shock, the absence of wound in tissues predisposed to necrosis, and the possibility that after a short time the tube may be dispensed with, ought always to be chosen instead of tracheotomy.—*Amer. Jour. Med. Sci.*

A CASE OF PORENCEPHALON.

Lloyd and Willard (*Amer. Jour. Med. Sci.*, April) report a case of porencephalon in which trephining was done for the relief of local symptoms, with death from scarlet fever. The patient was a boy, aged 7, with bilateral spastic hemiplegia, the right arm was the seat of athetoid movements, the legs, like the arms, were in a spastic condition, the knee-jerks were exaggerated, and ankle clonus was well marked on the left side. His general physical condition was good, but his mental condition was slightly impaired. His head was asymmetrical, but there were no scars or depressions. He came under observation in October, 1891, and a month later had a series of convulsions, after which the athetoid movements of the right arm were more noticeable and his mental faculties were weakened. There was absolutely no history obtainable as regarded his early life. It was determined to trephine over the motor area on the left side. When the dura mater was incised a considerable amount of cerebro-spinal fluid escaped and the finger entered a vast cavity, so that evidently a large portion of the cerebrum was absent. Scarlet fever developed on the third day after the operation, and the child died from its effects on the nineteenth day. On *post-mortem* examination a large porencephalon was found involving the left Rolandic region, extending anteriorly beyond the prefrontal fissure downwards almost or quite to the operculum, backward to include the superior parietal lobule, its area thus coinciding very closely with the area of distribution of the middle cerebral artery. In the mid-region of the cavity was a large crater-like opening extending into the lateral ventricle. The authors express the opinion that vascular disease or injury must have been the origin of the cavity in the brain.—*Brit. Med. Jour.*

SPONTANEOUS CURE OF DETACHED RETINA.

Marchetti (*Rif. Med.*, January 16, 1892) reports the following case: A man, æt. 55, observed during November, 1890, that the vision of his left eye was becoming dim. This dimness increased very rapidly, and in four days there was left only perception of light. Examination revealed extensive detachment of the temporal and frontal portions of the retina, and of a great part of the nasal portion. The detachment fluctuated in the lower portion with the ocular movements; in the other parts it was distended in folds. Tension was reduced, vitreous transparent, and disc normal. Vision was restricted to P. L., and perception of movements of the fingers in the temporal section of the field of vision only. Vision had been previously good, but each cornea had a central leucoma, the remains of inflammation many years previously. He was treated with pilocarpine injections and iodide of potassium, and advised rest in the horizontal posture. In February, 1891, having continued the treatment till then,

the eye was in the same condition, when quite suddenly on the 16th, he regained his sight. This followed, apparently, on a sudden rotation of his head towards the right side, the patient feeling immediately, as it were, a blow on his useless eye. directly after this he found that he could see objects distinctly and without any difficulty, and eight days after he could read small type quite easily. In June, when he again presented himself for opthalmoscopic examination, there was a light grey streak corresponding to the detachment, but no displacement whatever remained. The field of vision was nearly normal, save for colors, and the acuity nearly as good as before, having regard to the existence of the old leucomata. The author is inclined to attribute the sudden cure to a rupture of the detached portion, with escape of the subjacent fluid.—*Brit. Med. Jour.*

THE TREATMENT OF RECENT TRANSVERSE FRACTURES OF THE PATELLA.

Butcher (*British Medical Journal*, April 30, 1892) describes the following method of treating transverse fractures of the patelia:

The fragments are at first adjusted by the hands of an assistant and then a stout, curved, pedicle needle, armed with a long, stout, silk ligature, is passed through the skin about the centre of the outside of the knee, then pushed slightly upward subcutaneously until it reaches the upper border of the patella; the needle is now thrust through the quadriceps tendon as near to the upper part of the bone as possible. The point of the needle is then depressed and the skin on the inner side of the joint drawn up and the point of needle then thrust through and withdrawn, leaving the silk ligature in place. The needle is again passed as before from the outer side of the joint through the same opening and directed slightly downward until the lower edge of the lower fragment is felt. The needle is then thrust through the ligamentum patella, the skin in the inner side of the joint being drawn down and the point forced through the same puncture that is already occupied by the silk ligature. The needle, having been passed unarmed, is now threaded with the end of the silk ligature and then withdrawn, with the result that the silk disappears through the opening on the inner side of the knee and the two ends appear at the same opening on the outer side. The fragments are then rubbed well together so as to secure perfect apposition by the breaking up of clots, that may have intervened. The ends of the ligature are then drawn tightly together and knotted, with the result that the knot slips through the puncture. This ligature entirely surrounds the patella subcutaneously. There is no wound to dress and the joint is not interfered with. The joint is then dressed on a posterior splint and motion is not permitted for about ten days.—*Univ. Med. Mag.*

A NEW APPARATUS FOR THE TREATMENT OF SCOLIOSIS.

Schede (*Deutsche medicinische Wochenschrift*, No. 12) advises the apparatus here described in the treatment of scoliosis, and believes that more can be accomplished by this means than by measures formerly adopted.

The apparatus consists or a framework made of gas-pipe, consisting of four upright posts, joined together on three sides by cross-pieces. There are arranged two padded horizontal boards, which are movable, to hold the pelvis firmly. The anterior one is so padded that the symphysis remains free from pressure, so the development of the antero-posterior diameter of the pelvis is not unfavorably influenced. There is an upright bar from which is suspended the head-swing, held by a chain carried over two simple pulleys. A movable horizontal bar is also attached to this bar. By means of a screw it is put at such a height as will put the arms on the stretch when the head is in suspension. To the vertical rod is attached a ring made of gas-pipe of a size sufficient to go outside of the body of the patient. This ring is so arranged as to be readily raised or lowered. In this ring several upright rods are fastened which carry long horizontal screws with large pads on the end next to the body. Two of these pads act as shoulder-supports, which are provided with straps.

The others are used to make pressure and counter-pressure on the thorax with the view of correcting the deformity. To overcome the torsion, rubber adhesive plaster is placed on the back and sides of the patient; to this plaster is attached a cord which runs over a pulley on a level

with the attachment to the plaster, and pulling in a direction to overcome the deformity. Three to ten pounds are placed on the other end of the cord. The function of this is assisted by the pressure-pads, which, being on screws, are adjustable.

The head-swing is elevated until the patient rests on his toes. Half an hour is spent in the apparatus morning and evening.

Two cuts are inserted which greatly aid in elucidating this apparatus.

In bad cases a plaster of Paris bandage may be applied during the night, covering the pelvis and even part of the thighs.—*Amer. Jour. Med. Sci.*

OBSTETRICS.

TANGLING OF THE UMBILICAL CORDS IN TWINS.

Hermann (*Archiv für Gynœkologie*, Band XL., Heft. II.) describes the specimen from a case of knotting of the cords in twin pregnancy. The knot was between the first and second cords reckoned from the navel. Hermann believes that this condition, which occurs once in 5–6,000 pregnancies, is produced by long-continued violent movements of the body of the mother, as in dancing, riding, vomiting in the beginning of pregnancy, etc. The prognosis of tangling of the cords is extremely unfavorable for the children. In fifteen cases collected by him the pregnancy was interrupted eleven times and only one child was born living. In the other four cases, where the labor followed the regular end of pregnancy, five children were born living and three dead. The diagnosis of this condition during pregnancy is as impossible as its treatment. —*Univ. Med. Mag.*

DEATH AFTER RETROFLEXION OF GRAVID UTERUS.

Treub (*Centralbl. f. Gynäk.*, No. 19, 1892) observed an almost moribund patient with incarcerated gravid uterus and symptoms of acute peritonitis. There had been no defæcation for five days; vomiting had set in thirty-six hours before Treub saw her, and the bladder had been emptied twelve hours previously by the catheter. The uterus was replaced, but the patient died in two hours. At the *post mortem* the colon was found to be compressed by the gravid uterus, and it was already gangrenous. Acute peritonitis had followed this complication. Treub has collected fifty fatal cases of retroflexion of the pregnant uterus, and in no case was death due to gangrene of the intestine. The recorded causes of death were: uræmia, exhaustion, 13 cases; rupture of bladder, 11; septicæmia, 6; peritonitis after cystis, 10; pyæmia, 3; rupture of the peritoneum, 2; malpraxis, 5. Many cases, moreover, must have escaped observation or publication; nevertheless, it is not likely that sloughing of compressed intestine is otherwise than a very rare cause of death under the circumstances.—*Brit. Med. Jour.*

INHALATION OF OXYGEN IN OBSTETRICS.

Riviére (*Nouv. Arch. de'Obstét. et de Gynéc.*, April 25th, 1892) has found, as the result of much experience, that inhalations of oxygen are valuable under many circumstances, both for mother and child. Thus inhalation is serviceable in counteracting the evil effects of chronic or acute thoracic diseases during pregnancy, which so often cause abortion or premature delivery. In uncontrollable vomiting and anorexia inhalations, are also useful. After delivery inhalations superoxidize the blood, which appears to enable that fluid to resist sepsis. When a pregnant woman is ill or weak, inhalations always profit the the fœtus, whose nutrition is thereby improved. Rivière goes so far as to contend that the method is of service in placental diseases, or even in partial detachment of the placenta; it allows, he believes, more complete oxidation of the fœtal blood in the diminished area of sound placenta that remains. Altogether, however, he admits that inhalations are of more benefit for new-born children, whether they be emaciated from some cause which existed before birth, or continue to be thin for some period after delivery, owing to malnutrition.—*Brit. Med. Jour.*

GYNECOLOGY.

EUPHORIN IN GYNÆCOLOGICAL PRACTICE.

Bergerio (*Gazz. d. Osp.*, April 7, 1891) has tried the effect of topical applications of euphorin in 20 cases of ulcerative cre-

vicitis, in 4 of which the condition was complicated by eversion of the mucous lining of the crevix; after five or six applications the lesions were on the way to cure. He also used the drug in powder by insufflation and in a 1-in-3 alcoholic solution, and in this way cured some cases of septic endometritis. In order to avoid confusion, no other disinfecting agent was used at the same time, all washing out of the genital canal being performed with sterilized water.—*British Medical Journal*, suppl., April 30, 1892, p. 71.

THE TREATMENT OF UTERINE MOLE.

Fritsch in remarking upon the above case, describes his treatment in his own practice, and considers active interference strongly indicated. He employs the curette as soon as possible, as the safest and most efficient means of checking the hæmorrhage and terminating the case.

INTESTINAL OBSTRUCTION DUE TO DISPLACEMENT OF THE UTERUS.

Nélaton (*Nouvelks Archives d' Obstétrique et de Gynécologie*, 1892, No. 2) reports the case of a woman, aged twenty-eight years, previously in good health, who during a menstrual period was seized with colicky pains in the abdomen and vomiting, which persisted for three days, efforts to move the bowels being unsuccessful. Tympanities was excessive. On the fifth day gas escaped *per rectum*; on the eighth, the patient had a fluid movement, and no further observation was noted until the menses reappeared, when the symptoms of intestinal occlusion again developed. A rectal examination now revealed a cicatricial mass compressing the rectum at a point two and a half inches above the anus; the induration was continuous with the uterus, and was thought to be the remains of an old hæmato-salpinx. It was situated so deeply within the pelvis that it seemed to be more accessible through a vaginal than through an abdominal incision. The cul-de-sac of Douglas was opened from below, and adhesions attaching the retroflexed uterus to the rectum were divided, when the former was readily replaced. Examination *per rectum* then showed that the obstruction had been removed. The patient was discharged at the end of two weeks, and never had a return of the trouble.

Segond (*Ibid.*) reports the case of a patient, aged thirty-six years, who presented all the symptoms of acute intestinal occlusion. Under chloroform, a retroflexed uterus with a supposed fibroid at the fundus was replaced, by introducing the entire hand into the rectum, and the obstruction was overcome. Several months later vaginal hysterectomy was performed, and the tumor proved to be an ectopic gestation, which was removed successfully. —*Amer. Jour. Med. Sci.*

PEDIATRICS.

THE RADICAL CURE OF INGUINAL HERNIA IN CHILDREN.

Broca (*Revue Mensuelle des Maladies des l'Enfance*, April, 1892) describes the operative treatment of inguinal hernia in children, with report of seven cases.

This operation is of little importance in very young children.

(1) The tissues are thin and delicate.

(2) The parts are small and difficult to reach.

(3) A thorough anatomical knowledge is necessary.

Through fear of operations many surgeons have adopted other measures—especially the application of a bandage. This sometimes does result in the cure of these cases, but its application must be continued from two to three years. If the hernia be complicated by ectopion of the testicle, then operation must be resorted to. Operation in very young children—from one to three yeaas—would only be justifiable where a gradually-increasing hernia should suddenly become irreducible or strangulated. Strangulation is a rare condition at these ages. Colotomy was formely done in very young children for strangulation, with considerable success, but Broca believes the operation is rarely if ever necessary. Sometimes strangulated hernia can be reduced by pressure and carefully-applied taxis.

Two reasons are given by some authors why operations in earlier years should not be performed.

(1) Operations in children up to five years are generally grave.

(2) Before five years the continued use of the bandage generally cures.

But if great care should be taken during the operation and in the after-treatment of the wound there is but little danger. A congenital hernia, without being a pro-peritoneal hernia, may have a dilatation, retro-peritoneal or pro-peritoneal. These conditions were found in four adults operated upon. He thinks that pressure will cause obliteration of the inguinal canal; but how can that possibly effect this pro-peritoneal pocket.

Of the seven cases reported, the ages varied from five months to twelve years. One case at five months was cured by means of a bandage. The remaining six cases were all operated upon, and only one was complicated by ectopion of the testicle. All the cases resulted in cures in from four to eight weeks.—*Univ. Med. Mag.*

EXTIRPATION OF LARYNGEAL PAPILLOMA IN CHILDREN THROUGH A FENESTRATED TUBE.

Lichtwitz (*Arch. Clin. de Bordeaux*, No. 4, 1892) has successfully treated papilloma of the larynx and the upper part of the trachea by introducing a fenestrated tube. The position of the growth is first determined with the laryngoscope, and a tube of the pattern of O'Dwyer's tubes, but having a fenestra at a point corresponding to the point at which the growth is attached, is introduced in the ordinary way. The papilloma ought then to project into the tube. The operator introduces, with a finger as guide, a forceps or a *porte-caustique*, and removes or cauterizes the growth. The tube should be cylindrical and should have thin walls, and should be blackened on the inner surface. Examinations made on the dead body showed that the upper border of the tube always rested on the ventricular bands, and that the neck of the tube corresponded to the vocal cords. By noting this it was possible to cut the hole in the tube at a point corresponding very accurately to the site of the papilloma. As these growths are generally situated anteriorly, it is best, if the tumor cannot well be seen with the laryngoscope, to introduce a tube with an anterior fenestra, in the hope that the growth may project through it. If this fails, still more information is almost sure to be obtained. One case is related (a girl aged 4½ years) in which a mass of papilloma in the anterior commissure was removed piece-meal at six sittings, and the base cauterized.—*Brit. Med. Jour.*

HYGIENE.

THE BACTERIA OF MELONS.

Dr. Byron Halstead in the *Botanical Gazette*, November 11, 1891, describes a disease of melons and cucumbers on specimens from Bangor, Maine, and the central parts of New Jersey. To prove that the diseased plants were suffering from the results of the life of micro-organisms, numerous inoculations were made with the bacteria found in the diseased parts. The result was conclusive. The inoculated parts soon rotted and became affected in the same manner in which the original disease presented itself. Experiments were conducted also with seeds. Two lots, consisting of sixteen seeds, had been planted in two different pots, both of which were placed in the same conditions and surroundings. One of the pots was watered with water containing these bacteria, and only two germinations resulted, both of which died shortly, while in the other pot watered with pure water, the germinations produced good plants.—*Annals Hygiene.*

THE BEHAVIOR OF ANTISEPTICS TOWARD SALIVARY DIGESTION.

Under the above title Prof. Weber, of Columbus, Ohio, publishes in the *Journal of American Chemical Society*, January, 1892, the result of tests made under his direction by C. T. Fox. The agents used in the experiments were borax, salicylic acid, calcium sulphate and saccharine. The tests were made with one grain of starch in 15 c. c. of water, and 5 c. c. of saliva, with various amounts of antiseptic, and with varying times, ranging from 1 to 60 minutes. The effect was determined by estimating the sugar formed with the starch alone, and with the antiseptic added.

It was found that when the antiseptics were present in the proportion of 1 to 210 parts of the mixture, the diastasic action of the saliva was entirely arrested by all these agents during the first five minutes.

For the longer times, calcium sulphite was without effect, while borax retarded the action, and salicylic acid and saccharine completely arrested it. These last two agents prevented the action of saliva upon starch when present in the proportion of 1 in 420. Salicylic acid greatly retards the action when present in the proportion of 1 in 840; but not when the proportion was reduced to 1 in 1050. Saccharine showed no effect when the proportion was reduced to 1 in 840. Calcium sulphite failed to retard the action when present in the proportion of 1 in 420. Borax showed a great retarding effect, even in the proportion of 1 in 2100. These experiments were undertaken to determine the effect of the various preservatives for food containing them, and showed that mixtures containing them should not be permitted to be added to articles of food.

MEDICAL CHEMISTRY.

A TEST FOR THE PURITY OF TEREBENE.

A dispensing query which appeard in a recent issue of the *Chemist and Druggist* has suggested to Harold Wyatt, Jr., the following test as a ready means of detecting the freshness of a given sample of terebene:

℞ Iodide of potassium.....20 grains.
Compound powder of tragacanth (B P.)..... .....60 grains.
Boiling water to..... 8 ounces.—M.
Allow to cool before using.

Fifteen minims of the suspected liquid are added to 1 ounce of this test solution contained in a glass-stoppered bottle, and the whole set aside with occasional agitation for one hour, at the end of which time if a blue color makes its appearance the sample is considered bad.

The results vary somewhat with different terebene and turpentines, as the following table shows:

	1 hour.	12 hours.	24 hours.
A. Terebene.....	No color.	No color.	Pink blue.
B. Terebene.....	Faint pink.	Blue.	Dark blue.
C. Ol. terebinth rect...	Blue.	Blue black.	Blue black.
D. Ol. terebinth, comm.	Purple.	Blue black.	Blue black.

Sample A was from a well-known firm, and had been sent ont in 1 ounce capsuled bottles, so that the chances of oxidation were greatly diminished. Sample B was from the dispensing counter, and was contained in a 1-pound bottle three-fourths full.

Mr. Wyatt adds that if oil of lemon be old it will react in the same way as terebene, but fresh oil has no reaction. This might be useful as a guide to the quality of oil of lemon, one more trustworthy, perhaps, then the sense of smell alone.

The color produced in this test is, of course, formed by the reducing action of the $H_2 O_2$ contained in all old samples of turpentine and terebene, on the iodide of potassium and the subsequent formation of iodide of starch.

IODIDE OF CYANOGEN.

This poisonous compound, which is soluble in water or alcohol, has been recommended by Prof. Kobert as an efficient destroyer of all lower animals. A recent report of E. Merck recalls this fact, and suggests its use for the preservation of zoölogical specimens in general, etc.

It is to be stated that general caution must be exercised with this substance, since it is notably volatile even at the ordinary temperature. For this reason, also, its use as a permanent preservative of the objects before mentioned is rather problematical.

NEWS AND MISCELLANY.

"CHICAGO MEDICAL RECORD."

Chicago Medical Record, edited by Dr. Archibald Church, and previously published by W. T. Keener, of Chicago, is now being published by that well-known house, the M. H. Kauffman Medical Publishing Co.

CRAWFORD COUNTY, PA., MEDICAL SOCIETY.

At a meeting of the Crawford County, Medical Society, held July 5, 1892, the following actions were taken:

WHEREAS, The practice of criminal abortion is steadily increasing, and, in the numerous cases which prove fatal, it is next to impossibile to secure the conviction of the guilty party, because the testimony of the female—who is usually the only available witness in the transaction—is not received by the courts, whereby the evil-doer not only escapes punishment, but is encouraged in his work, therefore be it

Resolved, That we petition the Legisla-

ture of this State, at the coming session, to enact a law by which the dying declarations of a person, who may die from the effects of a criminal abortion, shall be received as evidence on the trial of any one indicted for the same as is now done in cases of homicide.

Resolved, That a copy of this resolution be sent to the various county medical societies of the State for concurrent action, and a copy also to each of the medical journals published within the State.

J. M. Cooper, M. D.,
Secretary.

A SLUR ON THE MEDICAL PROFESSION OF CHICAGO.

The *British Medical Journal* says: "Slow going Europe was much amused at the characteristic official methods employed at Chicago to meet the unpleasant effect produced by the publication of the figures representing the epidemic and endemic prevalence of typhoid fever in that city, and the extensive pollution of the lake water with which the city is served. There were 2,000 deaths reported from typhoid fever in 1891, and 311 deaths from typhoid in January of the present year. There was also evidence that the sewage of a city of some one hundred and eighty thousand persons passes directly into the lake, and that further pollution is brought about by means of the Chicago River, which communicates with the Mississippi as well as Lake Michigan. The simple reply made to this was that the doctors did not know how to diagnose typhoid fever, and that probably not more than four hundred out of four thousand cases so reported were correctly entered. We have been waiting with amused wonder for the response of the maligned medical faculty to this serio-comic retort, which would only be regarded as a bad and foolish joke in any other civilized city, whether of Europe or America. Meantime, it is instructive to note that instead of giving solidity or confirmation to the promise held out by Mr. MacCormach, the Commissioner in Great Britain, that the sources of water supply would be, in good time before the Exhibition, carried two miles further out into the lake, the *mot d'ordre* appears to be to give this significant hint to the doctors that for the future they had better register what they have been in the habit of recognizing as typhoid fever under some other name. This will not, however, diminish the mortality, nor will it add to the confidence with which future and, perhaps, more reassuring returns will be regarded by intending visitors to the Columbian Exposition."

INCREASED DRUNKENNESS IN WOMEN.

It is a matter of common belief that drunkenness in women is increasing very much. This view has received confirmation at an inquest a few days ago touching the death of Mary Zeig, aged sixty-seven, an habitual drunkard. Dr. Norman Kerr testified that death was due to apoplexy consequent on habits of intemperance. She had been drinking three weeks continually, and on Friday had gone to a public-house and taken a quantity of rum. Dr. Kerr said he had never seen such a number of drunken women as in the Whitsuntide holidays. He had frequently seen groups of four or five—some quite young—in a state more or less intoxicated. He could only attribute it to the hot weather. We are afraid the cause lies deeper than in the weather. Dr. Danford Thomas stated that he had held lately an increased number of inquests upon women, many comparatively young, whose death was clearly due to alcoholic excess. This kind of evidence is very serious, and emphasizes an evil which is about to be inquired into by a Department Committee. The jury were affected by the representations of the coroner and Dr. Kerr, and urged on the Committee the urgent necessity of compulsion in the treatment of chronic inebriates. The existing law is entirely inadequate. It is of use only to the wealthy, who can afford to go to retreats, and to those who have self-respect enough left to go voluntarily. Dr. Kerr suggested the creation of a special prison for the compulsory treatment of such cases. It might be called by some other name. But the suggestion is in the right direction and should be seriously considered by the committee. The condition of our chronic inebriates, and of the laws relating to them, are disgraceful to us, and deserve the anxious attention of statesmen of all parties. —*Lancet.*

CH. MARCHAND'S

PEROXIDE OF HYDROGEN.

(MEDICINAL) H_2O_2 (ABSOLUTELY HARMLESS.)

THE MOST POWERFUL BACTERICIDE AND PUS DESTROYER.
ENDORSED BY THE MEDICAL PROFESSION.
UNIFORM IN STRENGTH, PURITY, STABILITY.
RETAINS GERMICIDAL POWER FOR ANY LENGTH OF TIME.
TAKEN INTERNALLY OR APPLIED EXTERNALLY WITH PERFECT SAFETY.

Send for free book of 72 pages giving articles by the following contributors:

DR. PAUL GIBIER, Director of the New York Bacteriological and Pasteur Institute. "Peroxide of Hydrogen and Ozone—Their Antiseptic Properties." *Medical News* of Philadelphia, Pa.

DR. GEO. B. HOPE, Surgeon Metropolitan Throat Hospital of New York. "Some Clinical Features of Diphtheria, and the Treatment by Peroxide of Hydrogen." *New York Medical Record.*

NOTE.—Avoid substitutes—in shape of the commercial article bottled—unfit and unsafe to use as a medicine.

Ch. Marchand's Peroxide of Hydrogen (Medicinal) sold only in 4-oz., 8-oz., and 16-oz. bottles, bearing a blue label, white letters, red and gold border, with his signature. Never sold in bulk.

PHYSICIANS WILLING TO PAY EXPRESS CHARGES WILL RECEIVE FREE SAMPLE ON APPLICATION.

PREPARED ONLY BY

Charles Marchand

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{60}$ gr.), Atropiæ Sulph. ($\frac{1}{600}$ gr.), Codeia ($\frac{1}{60}$ gr.), Antimony Tart. $\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{60}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonial from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of the profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that the applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

86 Maiden Lane, **New York City**

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL & NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

PELVIC INFLAMMATION, SALPINGITIS AND PERITONITIS; UTERINE DISPLACEMENT.

By PROF. M. D. MANN, M. D.,
BUFFALO GENERAL HOSPITAL.

Gentlemen:—This patient I show you is a married woman, aged twenty-seven, who has had one miscarriage and six children at term, the last two years ago. She got up in two or three days after her last confinement and she has never been well since. The history of the case is quite a typical one. She entered the hospital last February complaining of pain in the left side, which began when she first tried to work after her last confinement, and of dragging pains in the back so severe that she was incapacitated. An examination revealed a large laceration of the cervix which was operated upon by one of my colleagues, circumstances at the time conspiring to make the operation a rather long one. The cervical wound united very nicely but, whether because of the length of the operation or not I do not know, a violent attack of pelvic inflammation including salpingitis and peritonitis occurred on the left side. Undoubtedly the woman had had a slight inflammation there previously to entering the hospital and the traction on the cervix lighted this up into an acute attack. This is one of the unfortunate results of operation on the cervix and I do not believe that it can be occasioned *de novo* by the manipulations necessary to the operation. At one time the patient's life was despaired of but she recovered and left the hospital in September.

I now find the cervix in perfect condition but there is a large mass of cicatrical tissue on the left side of the pelvis behind the uterus. It is as hard as cartilage and evidently consists of a mass of adhesions probably involving the tube within the peritoneum. The uterus is somewhat movable but not as much so as it should be and the parts are all very tender.

In this case the attempt was made to improve the woman's condition by repairing the cervix and while the question is no longer one of cervical lesion, it is doubtful if on the whole she has been benefited by the operation. We must remember such cases as this in advising trachelorraphy for these unpleasant results may follow an operation at which we suppose we have used the utmost care and gentleness. In considering what can be done to relieve the present state of affairs we must bear in mind that the woman is poor, that she is looked to to do the housework for a husband and six small children, that she is unable to work and that unless she can be restored to at least a fair degree of health she must remain an object of public charity while her family will be deprived of her services. She has been nearly a year under treatment, and, as you can see, without the improvement which we desire. I am convinced, therefore, that nothing short of a laparotomy will avail to relieve her from her present condition of invalidism. At the operation it will be necessary to break up adhesions, to remove the tube and ovary of the left side if they are diseased, as they undoubtedly are, and to put the uterus in its right place, fastening it there, it may be, by sutures and thus giving the woman a chance to recover her health. There is no history of gonorrhœal or of septic infection in this case and we have not a pus-tube to deal with but simply a chronic inflammation of the tube and peritoneum with the formation of cicatrical tissue. We may hope, therefore, by laparotomy and careful after-

treatment to improve very materially the patient's condition.

UTERINE DISPLACEMENT.

This patient comes to us from the Fitch Dispensary for an opinion with regard to her case. I have not seen her before and she speaks no language but German, but I will try to get the history of the case from her own lips. I do not know whether she will allow an operation or not.

She has had five children, the youngest nineteen months old, she has been sick three years, complaining of back-ache in the region of the sacrum, of pain in the middle of the abdomen and of leucorrhœa. Her menstruation anticipates; it stops and comes on again and sometimes it lasts eight or ten days and she loses considerable blood. If she works at all at the time she suffers a great deal of pain but otherwise she gives no history of painful menstruation. She is not obliged to go to bed at the time of her menstruation but simply to refrain from work. She says that now there is a period of three weeks between the catameniæ which last, ten days. This would make the epoch rather too long but we cannot rely too implicitly on the statements of women with regard to this function for even the most intelligent often make no mental note whatever of such things and cannot tell how often the periods occur nor how long they last.

She willingly consents to a digital examination and I find a lacerated cervix and enlargement of the uterus with backward displacement and some true collapse. The uterus is very movable, there having been no pelvic peritonitis to cause adhesions. The condition is about what we would expect from the history though we must bear in mind the fact that the history and subjective symptoms afford little clue to the exact anatomical condition existing in the pelvis. This is a common kind of case but the every-day cases are really much more instructive than the more interesting cases which we may not see exemplified more than once in a life time.

What was the order of events in this case? The probability is that the laceration of the cervix occurred before the other lesions and perhaps at the first of the labors. As a result, the uterus remained large, involution not fully taking place. Not only is the uterus subinvoluted but the ligaments and the vagina are subinvoluted, for the process is one which affects the other pelvic organs as well as the uterus. All the conditions are now favorable to displacement, the uterus being heavy and the ligaments, vagina and structures of the pelvic floor being relaxed. If, as in this case, there is in addition a tear of the perineum the support of the uterus is further weakened. The patient is a poor hard-working woman who has probably carried coal, done washing and strained herself in various other ways and in such a case it is only a question of time when the uterus will be forced backward in retroversion and downward in prolapse. These repeated strains will cause the uterus to keep coming down and in a little while the patient may find it outside the vulva. Then will come interference with the rectum and constipation and this in turn will necessitate bearing down and the increased pressure on the uterus will cause it to drag on the rectum and produce rectocele. In like manner a cystocele may follow and so things go from bad to worse. If, however, a woman with this trouble in an early stage is in a position in society so that she can rest and lie about on a lounge instead of being on her feet and engaged in hard work, she may drag along in comparative comfort and even recover spontaneously in course of time.

Menstruation tends to make worse the condition of a subinvoluted uterus, for it causes a periodical increase of the chronic congestion of the uterus. Hyperplastic growths are liable to occur in the endometrium and each menstrual period becomes a little longer than the last before it and more blood is lost so that anæmia gradually develops. The woman may fight against this if she has a good constitution and plenty of will-power, for a long time but she will generally back down in the end. This is not a very pleasant prospect for a woman and if we can relieve her and stop this downward career, it will certainly be very much to her advantage. In the present instance I think we can do so. The first step is to sew up the laceration in the cervix which is doing harm by preventing involution and it also lengthens out the vagina by just so much since the lips of the cervix are spread out. In this case there is no danger of lighting up a pelvic inflammation by this operation. By uniting the lips of the cervix, we take

up the slack in the vagina to a certain extent. Moreover the process of healing depends upon a change in the circulation which will favor involution. The perineum is not so much torn that a pessary cannot be retained and by introducing one as soon as the cervix has fully healed we can hold the uterus in place. If the peritoneum were badly lacerated we could restore it at the same time that we operate upon the cervix. If by passing the curette we find a polypoid endometritis with hyperplastic growths we will thoroughly scrape out the uterus and remove the growths. This will relieve the congestion and reduce the weight of the uterus. We may do this at the time we repair the cervix. Under this treatment the patient will in all probability get better and better. Will she ever be able to get along without the pessary? Sometimes that is the case. I examined a lady yesterday with just such a history as this patient gives. She wore a pessary for two years and then discontinued its use. It has been out for some months now and the displacement shows no tendency to return.

Even by the comparatively simple methods that I have indicated, the uterus regains its normal tonicity in many cases, while in others it remains large and heavy and it is necessary to perform some operation to hold it in place, either by shortening the round ligaments from without or from within. Many women will get along very well for years with the pessary and they often will not submit to a radical operation.

THE USE OF THE CONSTANT ELECTRIC CURRENT IN THE TREATMENT OF INTESTINAL OCCLUSION.

Dr. M. Semmola (*British Medical Journal*, 1892, No. 1625, p. 380) reports a case in which it was shown that there was an intestinal occlusion due exclusively to transient intestinal parlyasis through edfective innervation, in which the constant electrical current had a truly marvellous effect. The positive pole was, by means of a rectal catheter, carried into the bowel for about ten inches; the negative pole, olivary in form, covered by a cloth moistened in a saturated solution of chloride of sodium, was rubbed transversely over the surface of the abdomen for eight minutes thrice daily. Success followed after the first day of treatment.—*Amer. Jour. Med. Sci.*

Communications.

MORPHINISM IN ITS RELATION TO THE SEXUAL FUNCTIONS AND APPETITE, AND ITS EFFECT ON THE OFFSPRING OF THE USERS OF THE DRUG.

By T. J. HAPPEL, A. M., M. D.,
TRENTON, TENN.
EX. PRES. TENN. STATE MED. SOCIETY, AND PRES. OF THE WEST TENN. MED. AND SURG. ASSOCIATION.*

In an article by Lancereaux, of Paris, in which he describes the condition resulting from the long continued and excessive use of morphine, he says: "The special senses are not particularly injured, but the sexual appetite is abolished; the female becomes sterile, and ceases to menstruate; according to Loeinstein, her entire uterine apparatus may become atrophied. It is claimed that fatty degeneration of all the organs takes place."

Dr. Henry Lyman, of Chicago, referring to the effect of the use of morphine on the sexual apparatus, states that a characteristic phenomenon of the period of convalescence is a renewal of the sexual appetite: it being not infrequently exaggerated to an injurious degree. As to the truth or falsity of ALL these statements I am not fully decided; but that the female becomes sterile, and ceases to menstruate, I am prepared to most positively deny and prove. The existence of a sexual appetite or passion is generally denied by females, whether users of morphine or not. They are unwilling, in the better class, to admit the existence of such a passion, hence it cannot be safely asserted by any one that it has been abolished.

The long continued use of morphine *may* hasten the menopause, and hence hasten the atrophy of the uterus and its appendages, but, in the course of this article, I hope to be able to prove to the satisfaction of every one that women who use it at the rate of from eight to fifteen grains a day *may* and *do* menstruate, *may* and *do* conceive, and bear children at full term.

* Read before the Tenn. State Medical Society at its Annual Meeting in Knoxville, Tenn., April, 1892.

Case I.—Miss ——— had used morphine from 1873 up to the time of her death in 1890, 17 years. For the last ten years *confessed* to using one bottle (℥i) per week. It could safely be estimated that the amount used was at least ten to twelve grains daily. She began the use of morphine after she began to menstruate, before her uterus fully developed.

At irregular intervals, during her seventeen years use of the drug she menstruated.

Several examinations of the uterus were made during the last ten years of her life. A condition of hyperæsthesia of the vagina existed amounting almost to vaginismus. The uterus was found to be about 1½ to 2 inches in depth. Of course I could ascertain nothing about the sexual appetite in this case, though another female in the family, who used less morphine confessed to the habit of masturbation.

Miss ——— finally died of abscess of the lung.

Case II.—Mrs. ———, a widow, had for a long time been a user of morphine to excess. I have had no way of ascertaining in her case the quantity used. Suffice it to say, in regard to the loss of sexual appetite, and the question of sterility, that it was reported that she frequently cohabited with men, and was finally delivered of a child, which lived for a short while, probably one year and then died.

Case III.—Mrs. X, married, used morphine, though not very excessively for two or three years. She became pregnant, and was delivered of a fine, large child which throve and grew rapidly, but died during its first summer.

Since the death of that child she has never conceived, but in her case there exists, and has existed for some time, chronic endometritis with lateral displacement. She claims to have no sexual appetite, but of that I have very serious doubts.

Case IV.—Mr.——, a widower, using morphine, not less than eight grains per day, married.

Within eighteen months after his marriage, his wife, a delicate lady, gave birth to a fine boy. This child has developed rapidly, and to all appearance has suffered not at all from the vice of its father. Before the child was more than a year old, the father died from the morphine habit, being reduced almost to a skeleton.

Case V.—Mrs. ——, used morphine for years, and at the time of the birth of her third child was consuming eight to ten grains a day. In 1884 she gave birth to a well nourished and apparently perfectly developed boy, weight seven or eight pounds. Within twenty-four hours the child began to grow restless and nervous. In the next twenty-four hours the nervousness increased, and the child frequently became cyanotic. On the third day, all the symptoms grew worse, the cyanotic condition continuing almost all the time. On the fourth day the child died. Not knowing anything about the mother's habits, opiates were very sparingly administered to the child, and its death was pronounced due to non-closure of the foramen ovale, which I think did exist in the case.

In the latter part of 1880, another child was born, the mother still using morphine in an increased quantity.

The history of the first child was repeated in the second. It died on the fourth or fifth day thoroughly cyanosed.

In 1889, the mother still using morphine, another child was born, which died in the same way, on the fifth or sixth day. In 1892, the mother, still using morphine, consuming two drams per week, about seventeen grains per day, was confined. Her labor was natural, and of short duration, everything passing off nicely. The child was finely developed, well nourished, weighing nine pounds. For the first twenty-four hours everything progressed favorably. The mother, however, was allowed to get too much from under the influence of morphine and became nervous, and complained of a general malaise, with some pain in the right lung.

The husband was cautioned to keep up the usual quantity of morphine to protect against shock and after-pains. In spite of the directions given, etc., morphine was practically discontinued and at the extirpation of forty-two hours after the termination of labor, a severe convulsion came on. The patient was rapidly morphinized, but before a sufficient quantity had been administered to saturate the system, a second convulsion came on, not so severe as the first. Pilocarpin was then administered, and no further convulsions resulted for twenty-four hours, when, the morphia, having been neglected, a third slight convulsion developed. From that time on,

two grains of morphia were given hypodermically every four hours regularly. The patient after improving rapidly until the seventh day, suddenly died at the end of the eighth day with congestion of the lungs.

The infant on the third day became cyanotic, and extremely nervous and fretful. Tr. Opii Camp. had been begun on the second day in two drop doses every two to four hours. The doses were increased to five drops, till, with aid of the free use of whiskey, the child was quieted. On the fifth day the cyanosis diminished, but the child appeared to be in a moribund condition. Paregoric and whiskey were again freely used, fifteen drops of the former being given within six hours, and during the night of that day, twenty drops were administered before midnight. The quantity of the opiate and the whiskey was gradually diminished, the former being dropped by the twelfth day. The child is still living, just one month old, but has an aged, pinched look. Its digestion has been poor.

In this case the morphia habit had continued for at least ten years.

If the sexual appetite was abolished, of which fact I know nothing, yet the power of fecundation had not been disturbed, nor had menstruation been any more irregular in her case than in other child-bearing women.

Case VI.—A healthy married woman menstruated scantily all her life. Family history excellent. Suffered from sick-headaches. After marriage began using morphine for relief from the severe pain. Her first child was born in 1885 two years or more after her marriage, before she began to use morphine regularly. He is a stout, healthy, vigorous, well-developed child, nine years of age. Between the birth of this child and her next pregnancy, she became a morphine user. In 1887 she gave birth to a puny, delicate, cyanotic child, emaciated at birth, and troubled with diarrhœa. At that time I did not suspect the morphine habit. The simple remedies usually given to babies did not control its diarrhœa. Paregoric had little or no effect even in five or six drop doses repeated every two or three hours at the age of three days. I began using Dover's powder, giving from two to three grains at a dose every two to four hours.

*The child has since died aged about five months.

The child became more quiet, its bowels were controlled, and at the end of the first month of its life, the use of opiates was dispensed with.

That child, now in its fifth year, is not larger than it should be at three, has a puny, sickly look, and although never really sick, is never well.

In 1887 the mother was using morphine, not less than ℥i per week.

She became pregnant and was delivered of a fine, well-developed child.

In twenty-four hours it became nervous, fretful, cyanotic and died perfectly cyanosed on the third day. The mother had a good "getting up" and in 1891 was delivered of another child in fair condition. At the time of the birth of this child, and in fact all through the pregnancy, she used at least eight or ten grains of morphine per day. The history of this fourth child is a repetition of that of the third. On the fourth day it was buried. It died cyanosed.

In this case the mother denied all sexual appetite. Her menstruation was as regular after she began the use of morphine as it was before she began it, never having been very free, lasting at most one or two days.

Opiates were administered freely to the last child, but to no avail.

Case VII—A mother, a confirmed morphine eater, using from eight to ten grains per day, has two living children, one deaf and dumb, and the other a blind idiot, she miscarried of a third child at six months. She suffers from chronic uterine disease.

Case VIII.—A mother who was a confirmed "opium eater" gave birth to two boys and a large family of girls. One of the boys died at the age of 22 to 25 of chronic alcoholism. The other is notoriously of no-account.

I might cite more cases of a similar character, but the ones already given will answer my purpose to impress the point I desire to make.

First, in reference to the children of morphine users. My experience thoroughly satisfies me that when the *mother* uses morphine habitually, the child is born with some defect of the heart—a congenital heart disease: either there is non-closure of the ductus arteriosus, the foramen ovale, or the pulmonary orifice, and in some cases, the inter-ventricular septum is defici-

ent. I do not pretend to assert that the use of morphine is the sole cause of these defects, but that when morphine is used to excess, in the large majority of cases the deficiencies do exist.

Generally, the first intimation that you have of any defect in the development of the child, is that after becoming restless and fretful, a cyanotic condition supervenes. The nurse calls your attention to the fact that the child is "blue." The child may have been, and frequently is born, as shown in the few histories given, apparently in fine condition. It rests well for the first twelve or twenty-four hours. It is reported to you as an unusually "good child," sleeps nearly all the time, does not want to be nursed, etc. On the second day, however, you are apt to be informed that the child is fretful, restless, colicy, and then later on, that day or the next, that the child becomes blue at times. As a rule this condition grows worse unless you suspect, or know, the cause of the trouble and begin the free use of opiates and stimulants. This condition is easily understood, and the need of the treatment suggested, comprehended, if you bear in mind the fact that the child is born an opium user.

Its blood is, so to express it, saturated with the drug. The mother has lived on it, and the fœtus has developed under all of its baneful influences.

To finish up and perfect the heart is the last work to be done, and the closure of the foramen ovale and other portions of the heart mentioned being left to be finished after the child has begun its separate existence, the supply of opiates being suddenly cut off, the equilibrium of the nervous system is destroyed and nature's finishing work suspended.

The closure of the foramen ovale could not be permitted as long as the child existed in utero, and now the work cannot be carried on, with the nervous system crying out for opium: hence, the restlessness which induces irregularities of circulation, blueness, etc.

If this cry of the nervous system can be quieted and the child nourished, nature may be, and sometimes is able to complete her work. This is shown in the case of the first child of Case No. VI. and the last one of No. V.

Both these children were promptly saturated with opium and whiskey, both of which were gradually withdrawn, the child being all the while well nourished; with the result in both cases of a cure so far as the congenital heart disease is concerned.

There can be no possible trouble in understanding the rationale of cyanosis in children born of morphine habitues, if they have ever once witnessed the horrible agony of a morphine slave, when it is suddenly taken from him. It has been aptly described as "the tortures of the damned."

In every case of cyanosis in the newborn infant, the first step must be then to ascertain, if possible, the habits of the mother in regards to the use of opiates. This will be found no easy task. The confirmed user of the drug will deny the fact as promptly as the question is asked, but the inquiry must not stop with the mother alone.

The husband and nurse must be interrogated, and still if no light is thrown upon the question, if there is the least reason to suspect the habit, opiates in tentative doses, either in the form of Tr. Opii. Camp. or Pulv. Ipecac Comp. must be cautiously given. If the infant is found to tolerate them well, your case can be taken as almost proven.

Under the supervision of the physician, the opium and the whiskey, after you have quieted the child fully, must be slowly and carefully withdrawn, being sure not to reduce the dose too rapidly.

It is still an undecided question in my own mind, however, whether, considering the good of the child alone, it were not better to allow it to die.

Morphine becomes "me judice" a disease transmissible by heredity almost to as great a degree, and in the same way that tuberculosis and such like diseases are handed down. Not that the disease itself is transmitted, but a condition, a soil, a nidus or whatever you may be pleased to call it, is handed down to the child, and some fortuitous circumstance develops to disease.

The offspring of the victim to the morphine habit has a condition of the nervous system that when once subjected to some exciting cause develops the habit rapidly.

Dr. T. D. Crothers, of Hartford, Conn., in The Medical and Surgical Reporter of March 5th, 1892, in an excellent article, shows that the morphine habit is frequently transmitted to the offspring of the users of the drug in the form of a neurotic dia-

thesis; rather that the children have inherited from their parents some condition of the brain which predisposes to the developement of nervous diseases and that in some cases there is a special inherited tendency to use opium.

He cites as follows:

To a mother who was a morphine user, and a hypochondriac father, two children were born. Both were healthy and highly educated. Both became opium users: one at the age of 30; the other at 24. Again—

To a father and mother, both opium users, three children were born.

The parents died. The children knew nothing of their addiction to opium.

All of them became morphine users before they reached the age of fifty years.

Third. Both parents were neurotic and probably opium users.

They died leaving an excessively nervous, irritable infant. Morphine was accidentally used to quiet it, and from that time forward it would become delirious without a daily dose of morphine.

It died at five years, a confirmed morphine user.

Again—Five children of unknown parentage became confirmed opium eaters.

Many more such cases might be cited. He concludes this part of his article as follows:

"The relief which this drug brings on all occasions and its impulsive use are unmistakable indications of a distinct opium diathesis."

A complex diathesis sometimes exists in many opium cases. Alcoholics sometimes use opium irregularly, and transmit that diathesis to their offspring and vice versa.

Morphinism and alcoholism are frequently interchangeable, the slaves of the one turning at times to the other for a rest.

Whilst this opium diathesis is present in a majority of cases, yet it must not be forgotten that in a small minority of cases, a sensitiveness to the effects of opium which is remarkable exists—a very small dose producing an overwhelming effect at times, and in other cases producing such a degree of emesis and prostration as to alarm the whole family.

Whenever then an opiate, rapidly and pleasantly, relieves pain with nothing except a pleasing sense of cure, then an opium diathesis must be suspected and the drug administered, if at all, with the greatest circumspection. One dose demands another, and unless the physician knows exactly where to stop, and when, a morphine habit is rapidly developed.

Especially is this true where the opiate is administered hypodermically.

The number of victims to the morphine habit has rapidly increased since the introduction of the hypodermic syringe. The effect is rapid, pleasant and seductive.

I would not condemn the hypodermic syringe. A physician who does his whole duty cannot do without one, that is always ready for an emergency.

It is not the syringe but the unthoughted use of it that is to be condemned.

The quantity of opium used in the United States has largely and rapidly increased. In 1854 the amount imported was about 72,000 pounds, in 1880, 372,000 pounds, in 1890, about a half million pounds. The legitimate demands of medicine would call for an increase in quantity commensurate with the increase in population, but see the contrast.

The difference between the legitimate demands of medicine, and the actual amount used shows how much, approximately, is consumed by opium eaters.

This fact no doubt largely accounts for the rapid increase in the number of cases of insanity, idiocy and imbecility in the present generation.

The custom is to charge the increase to the American method of living, with its rush, push and scramble to amass wealth, but the rapid increase in the per cent. cannot be explained in that way, but the father and mother, or one, or the other, being addicted to the use of opium to excess, their sins are visited upon the children of the third and fourth generations, and we see the results.

This paper is written for the purpose of calling the attention of the profession to the evil, and to place each one as a sentinel upon the wall to watch and record the effects of this blight upon modern civilization.

I may have discovered nothing new, I do not claim that I have, but I propose to put upon record my own experienee with a limited number of opium-takers.

It was the celebrated Dr. Bowling, I believe, who said that if we all read more, we would find that we had discovered fewer new things.

I do not find the literature as abundant upon this subject as it ought to be, hence this mite.

COMMINUTED FRACTURE OF THE SHAFT OF THE FEMUR, WITH REPORT OF A CASE.*

By F. H. LAY, M. D.,
CONSULTING SURGEON TO ST. LUKE'S HOSPITAL, DENVER.

Comminuted fracture of the shaft of the femur presents more than ordinary difficulty to be overcome, since from the great injury to the bone and surrounding tissues, a perfect reduction of the fracture and fixation of the fragments become almost impossible; and since the liability of non-union in feeble subjects is always an unpleasant possibility.

Many of the gentlemen present remember no doubt the prolonged discussion about ten years ago between the late lamented Dr. Frank H. Hamilton and Dr. L. A. Sayre, the question in dispute being whether a fractured femur properly treated should result in a bone of normal length; Dr. Hamilton contending that under the best of care, a slight shortening was in the majority of cases inevitable, there being a molecular absorption of bony tissue at the fractured surfaces.

The committee appointed by the American Surgical Association, in 1890, to report what should be deemed a satisfactory result of treatment of fracture of the shaft of the femur, submitted the following conclusions which were adopted by the Association: "A satisfactory result has been obtained in the treatment of the fracture of the shaft of the femur; (1) when firm bony union exists; (2) when the long axis of the lower fragment is either directly continuous with that of the upper fragment, or the axes are on parallel lines, thus preventing angular deformity; (3) when the anterior surface of the lower fragment maintains nearly its normal relation to the plane of the upper fragment, thus preventing undue deviation of the foot from the normal position; (4) when the length of the limb is either exactly equal to that of its fellow, or the degree of shortening falls within the limits found to exist in 90 per cent. of healthy limbs, namely, from one-eighth of an inch to one inch; (5) when lameness if present, is not due to more than one inch of shortening; (6) when the conditions attending the treatment prevent other results than those obtained."

In view of the above, a surgeon should not be discouraged to find his femur fractures recover with slight shortening.

However, our aim should always be *perfection,* and this can only be accomplished by using the best methods in our treatment

Last March a case of comminuted fracture of the femur was placed in my care. I found two oblique fractures; one through the upper third just below the trochanter major, the other through the center of the middle third; the limb being shortened four inches, and the central fragment being very movable.

Having tried various methods in previous cases, and being best pleased with the Hodgen splint, suggested to me by Dr. L. E. Lemen of this city, I concluded to use the Hodgen for this fracture, and therefore dressed it accordingly; the limb being supported, suspended and strongly *extended* thereby, and also the fragments being further held immovably in position by four padded short splints which aided in preserving the normal antero-posterior curvature of the bone.

Passive motion of the knee and ankle joints was made occasionally after the fourth week, but the splints were worn seven weeks, at the end of which time union in both fractures were firm. The long axis of the lower fragment is in direct line with that of the upper, and by most careful and oft repeated measurements I find no shortening whatever.

This certainly is a test case and proves conclusively to my mind the value of the Hodgen splint; also that the ground assumed by my teacher, Dr. Sayre, that a fractured femur properly treated should be of the same length after as before the injury, is correct.

HOW TO REMOVE NITRATE OF SILVER STAINS FROM THE FINGERS.

A correspondent of the *Scientific American* gives the following harmless process:

First paint the blackened parts with tincture of iodine, let remain until the black becomes white. The skin will then be red, but by applying ammonia the iodine will be bleached, leaving white instead of black stains of nitrate of silver.

RESECTION OF THE INTESTINE WITH CIRCULAR ENTERORRHAPHY.*

By P. M. JEWELL, M. D.,
OSSIAN, IOWA.

On Nov. 28th, 1889, in consultation with Dr. Lewis, of Ridgway, Iowa, I saw Rollin B., aged 9 years and 7 months. He had been ill for about two months with his present trouble, the symptoms of which now considered of severe spasmodic pain in the abdomen referred to the left side, tympany, frequent attacks of vomiting, protrusion and gradually increasing emaciation.

There was a history of an attack of peritonitis, some 4 or 5 months previously which had run an acute course, the boy being confined to the bed for about two weeks. He had apparently fully recovered from this attack with the exception of some irregularity of the bowels accompanied with colicky pains, which was usually relieved spontaneously or by domestic remedies and followed by a diarrhœa lasting some days. He had been gradually failing until now he was reduced to a living skeleton and was so weak that he was unable to assume the sitting position in bed without complaining of vertigo. When not suffering from the paroxysms of pain, he was comfortable, cheerful and inclined to be playful. Faculties of mind unimpaired. His temperature was normal at the time of my visit, pulse rapid, soft and weak, extremities cold, breathing rapid and superficial from pressure on the diaphragm of the distended abdominal viscera and the extreme anæmia present.

Taking into consideration the history, symptoms and condition of the patient, my diagnosis of the case was that he was suffering from a gradually increasing stenosis of the bowel, produced, no doubt, by bands of adhesions resulting from former attacks of acute peritonitis. Advised operation as the only hope of relieving the occlusion and saving the life of the boy.

Dr. Kessel, of Cresco, subsequently saw the patient and without a previous knowledge of my opinion came to the same conclusion as regards diagnosis, prognosis and treatment. As throwing some light upon the development and history of the case, I append some notes kindly furnished me by Dr. Lewis, as follows:

October 5th, 1892. Was called to see Rollin B., aged 9 years. Found temp. 102.5°, pulse 120. Severe pain in left hypochondriac region. Bowels constipated, vomiting, skin hot and dry.

October 6th, 8 A. M. temp. 104° F., pulse 128. Other symptoms and conditions unchanged. 4 P. M. Bowels moved freely; temp. 103° F., pulse 120. Pain less severe.

October 7. Rested well through night. Temp. 102.5° F., pulse 120. Vomiting once; no pain.

Oct. 8. Temp. 102., P. 120. No pain.

Oct. 9. Temp. 100°. P. 100. No pain.

Continued to improve until November 9th, when he again began vomiting and complained of great pain in the left hypochondriac region when peristalsis occurred. Ate very little. Opiate administered. Patient continued vomiting and complaining of severe pain in hypochondrium with a temperature of about 100°., and pulse of 110 until the 29 of November. He then rested well, and ate some in the morning. At night had an attack of urticaria. Laxative administered.

Nov. 30th. Urticaria disappeared.

Dec. 1st. Vomited several times. Fæcal odor. Temp. 98°. Pulse 102. Patient emaciated very much. Very weak.

Dec. 2nd. Temp. normal, and pulse 94. Took beef tea. Rested well all day. Restless all night.

Dec. 3rd. Temp. 98,° and pulse 98. Severe pain in left hypochondrium.

Dec. 4th. Temp. 98°, and pulse 98. Pain severe. Hypodermic of morph. sulph. gr., ¼, and atropia sulph. 1-150. Pain relieved. Patient continued in about this condition, vomiting a great deal and pain all the time unless under the influence of an opiate up to Dec. 10th, on which date he was operated upon."

The parents, having thoroughly satisfied themselves of the fatality of further dependence upon medical aid finally consented to an operation. During the succeeding interval the necessary antiseptic arrangements and details were overseen and carried into execution by Dr. Lewis. so that by Dec. 10th, everything required

*Read before Iowa State Medical Society, May, 1892.

for the performance of an aseptic operation was perfected.

At about 10.30 A. M. the patient was placed upon a table and ether administered by Dr. Lewis. Dr. Kessell ably and very efficiently assisted me in the operation.

An incision was made in the median line below the naval and subsequently enlarged some distance above. My dissection was inadvertently continued directly through the omentum before I knew I had reached the peritoneal cavity, for the adhesions at this point were so firm and intimate between the attenuated folds of the omentum and the parietal peritoneum that the line of separation was undistinguishable in the poor light we had to work in. (The day was very unpropitious, being cloudy, rainy and consequently very dark.) When found the source of obstruction was seen to be several loops of the ileum and the lower border of the omentum all firmly matted together and intimately attached to the fundus of the urinary bladder by inflammatory adhesions.

In my efforts to separate these attachments and adhesions, which I am sure were made with great care and deliberation, I had the misfortune of making several longitudinal tears into the intestine, varying in length from ½ to 1½ inches, and had torn the bowel entirely in two on the distal side of the stricture and its attachments. It was simply an absolute impossibility to distinguish a line of separation between these agglutinated tissues, and the dissection was continued in the direction most likely to keep clear of the bowel walls and in the cicatricial tissues, with the result above stated. At last, however, I succeeded in peeling the agglutinated mass off the fundus of the bladder complete, without opening into this viscus. The entire affected mass was now brought outside the abdominal cavity, and placed on aseptic towels (towels which had been wrung out of hot boiling water) and the general cavity protected by other similar towels placed in and over the incision and changed occasionally to maintain the proper degree of warmth.

The work of separation of the adhesions was now completed, and wherever an opening through the bowel wall had been made, a coarse ligature of aseptic silk was thrown around the tube on each side of the opening about three inches distant and tied close enough to prevent any escape of fæcal contents. The bowels were not much distended with fecal matter or gas.

In all suturing of the intestine the finest black silk and ordinary fine, straight milliner's sewing needles were used. The thread and needles had been treated to a bath of boiling water and acid (carbolic) in the proportion of about 1:25 had been subsequently added. From this solution they were taken as required for use. Closure, which fortunately had occurred directly opposite the mesenteric attachments of the longitudinal rents, was now proceeded with. Interrupted Czerny sutures including the mucous and muscular coats of the bowel were introduced every ¼ to ⅜ inch and tied. Over these the serous coats were brought together by an interrupted or by a continuous, right-angle Lembert suture, introduced from ⅛ to $\frac{3}{16}$ of an inch apart. Wherever the peritoneal coat has been torn off, the right-angle, continuous Lembert suture was also made use of, to serve as a support to the denuded bowel and to prevent subsequent adhesions. The intestine at the point of the occlusion next received attention.

At this point, about ¾ of an inch of the bowel was constricted to a narrow tube, which felt under the finger like a firm cord, and had a passage way through it about the size of a rye-straw, or the point of an ordinary pencil. Near this constriction, but far enough away to secure a section of full size, the bowel was cut across by a single stroke of straight scissors and at right angles to its long diameter. The edge of the ragged (distal) end was trimmed off smoothly and far enough away to secure a section of full calibre. A triangular piece of the mesentery was also removed, the base fully one inch in length corresponding to the section of gut exsected, and the apex pointing toward the spinal attachment of the mesentery.

After the hæmorrhage had been controlled by a few fine silk ligatures the parts were thoroughly cleansed in boiled water, and the flaps of mesentery brought together by a number of interrupted Lembert sutures. When the intestines was reached, the mesenteric attachment of each end was carefully brought into apposition, the work of uniting the two imperfect cylinders began. In doing this a Czerny suture was introduced at the mesenteric junction and securely tied. *Here is*

the vulnerable point in circular enterorrhaphy *in the repair of bowel resections*, leakage being very apt to occur, from the very evident fact that the Czerny here cannot be reinforced and strengthened by a Lembert suture behind it. The first Czerny suture in the repair of the bowel resection was made to enter and pass through and include the mucous and muscular coats about three or four sixteenths of an inch from its free border and directly over the center of the mesenteric attachment, passed across the gap to the opposite side, entered directly over the mesenteric attachment, underneath the mucous and muscular layers and brought out on the mucous surface about three-or four-sixteenths of an inch from the free border. This was now carefully tied, the knot, of course, falling within the lumen of the gut. Two more Czerny sutures were now introduced and tied, one on each side and about one-fourth of an inch from the first. These were immediately reinforced by the introduction of a Lembert on each side of the mesentery, near the junction of this tissue with the intestines. The Lembert suture is usually described as including the serous coat alone, but in using this variety of suture, I aim to and did include a bundle of the circular muscular fibres of the gut in the grasp of each thread, and think it much better and stronger than including the serous coat alone.

Wyeth describes what he calls an "intermediate suture," which is made to enter the serous coat about $\frac{3}{16}$ of an inch from its free border, passed through this and the muscular coats and out at the free border across the gap and made to include both muscular and serous coats on the opposite side in the same way. He recommends that this suture be used in conjunction with the Lembert and alternately therewith.

I cannot see any advantage in this over the Lembert suture when this is made to include the peritoneal and muscular layers. in fact, I think the latter has advantage over the former. If each Lembert suture has within its grasp a bundle of muscular fibres, its hold upon the opposed structures must be more firm and secure, than when serous fibres alone are included within its grasp. When the gap is thus closed. there will be about $\frac{6}{16}$ of an inch reinforced on each side bg a ring of muscular fibres behind it, and held in place by the same set of sutures that maintain the surface in contact. This will continue to do, so long as the muscular fibres in the bite of the sutures maintain their integrity, and that they are capable of doing so and offering greater resistance to strain and tension than the serous coat there can be no reasonable doubt.

The Czerny sutures were introduced about $\frac{1}{4}$ to $\frac{3}{8}$ of an inch apart and the row kept one or two stitches ahead of the row of Lembert. The object of this was to invert the naturally everted ends of the bisected intestine with the Czerny and to clinch the inversion and coapt the serous surfaces at the same time by the Lembert suture. Thus. one suture is the natural complement of the other. A slight difference in size seems to exist between the ends of the afferent and efferent tubes, and an allowance had to be made in suturing that this difference be distributed evenly over the line of coaptation and not concentrated all in one place. This necessitated introducing the sutures a little farther in one end than the other. When the sutures were all in the temporary constricting ligatures were removed. No leakage occurred. The intestines were now carefully washed with boiled water and returned to the abdominal cavity. The ragged omentum was ligated in sections, the distal extremity amputated with scissors, washed with boiled water and returned to the abdominal cavity.

After all discoverable adhesions had been broken down, the abdominal cavity was several times thoroughly flushed with hot boiled water, poured directly into it from a pitcher until the flushings returned unstained, then sponged out and dried carefully. All hæmorrhage having ceased the omentum was spread out over the intestines in as natural a manner as possible, and the wound in the abdominal parieties brought together by interrupted sutures of strong silk thread, no drainage tube being introduced.

A few intermediate sutures were introduced to secure nice coaptation of the superficial structures and the dressings then applied. These consisted of pulv. iodoform along the line of the incision overlaid by several thicknesses of sublimated gauze, then adhesive straps laid at right angles to the incision then a large pad of salicylated cotton, then one of ab-

sorbent cotton, and over all and holding the others snugly in place a few turns of a wide flannel bandage.

The etherization had been discontinued towards the latter end of the operation, until as the last sutures were being tied and the dressings applied, the consciousness of the patient was quite restored. This was a wise provision as by this time the shock was profound, the operation having lasted fully two and a half hours. The patient was now quickly transferred to a warm bed and hot blankets and dry heat generally applied.

Morphia and atropia were administered hypodermically to assist in the restoration of the vital powers and to control pain and secure quiet. The doses were repeated through the night as indicated.

The notes of the case for the next four days taken at the bedside and furnished me by Dr. Lewis are quite interesting. From them I quote as follows:

Dec. 11, 7 A. M. Temp. 104° F., Pulse 140. Quinia sulph. and opium per rectum. Quinia also by mouth; 4 P. M. Temp. 104° F., pulse 140; 10 P. M. Temp. 103.5° F., P. 136.

Dec. 12, 8 A. M., Temp. 102.5° F., P. 130; 4 P.M., Temp. 102° F., P. 130; 10 P. M., Temp. 101.5° F., P. 130. (Beef peptonoids per rectum).

Dec. 13, 8 A. M., Temp. 100° F., P. 120; 4 P. M., Temp. 100° F., P. 120; 10 P. M., Temp. 95° F., P. 120.

Dec. 14, all day Temp. 99° F., P. 120.

Dec. 15, all day Temp. 98° F., P. 120. (Dressed wound, doing nicely).

Dec. 16, 17 and 18, Temp. normal, P. 110 to 100; 18th, dressed wound. Removed every second stitch. Patient ate an orange.

Dec. 19, 20 and 21, Temp. normal. Bowels moved spontaneously without pain on 21st, 10 days after operation.

Dec. 22. Dressed wound. Removed all stitches. Wound healed.

Dec. 23, 24, 25 and 26. Nothing to note.

Dec. 27. Removed all dressings. Reapplied adhesive straps.

Dec. 28. Temp. normal; P. 90. Patient sat up and continued to improve until recovery was complete, and up to date, Dec. 1891, when notes had been received, boy had never had a pain or been indisposed in any way.

After the currents of life had been reestablished in their original channels and the shock of the operation had passed away the subsequent history of this patient is uninteresting, but considering his extreme emaciation and the low ebb of his vitality at the time of the operation; the very complicated series of surgical measures to which he was subjected and the length of time necessarily consumed therein, the final result is interesting to every man engaged in the practice of medicine and surgery.

A combination of such extensive and serious lesions as were present in this case is not likely to be met with in a very large number of cases. It has been my fortune to see quite a number of similar cases and to have made *post mortems* upon many of them, and I have never seen any in which an appropriate operation would have been less likely to succeed than in this.

The method here adopted, the materials used and the technique practiced, are not new or extremely difficult. They are the common heritage of the profession. They lie at every man's door, all he has to do is to put forth his hand and appropriate them.

I am not prepared to say how many fatal cases of intestinal obstruction occur annually, even in the State of Iowa, but judging from my own observation and experience, there are certainly not a few, but this I can confidently assert, the majority of these might be saved by a timely resort to surgical interference.

Resection of the intestine with invagination and closure of the resected ends by a double row of Lembert sutures and the establishment of a mucous fistula between the two by Senn's approximation, decalcified bone plates, may be possible, from the fact that these appliances are not ordinarily a part of the operator's surgical armamentarium and they require time and trouble to manufacture or to secure by purchase.

The same objections apply to Abbe's catgut approximation rings, Brokaw's segmented rubber rings, Robinson's rawhide plates, Mata's or Davis' solid catgut rings or mats, Baldy and Ashton's solid rubber rings, and nearly all appliances of this character with which I am acquainted with the possible exception of Dawbarn's vegetable approximation plates made from sections of raw potatoes, (*vide Med. Rec.*

June 27, 1891). These, however, require further trial to prove their efficiency for the uses to which they are put. I do not know of their being used in actual practice upon the living human subject. They would seem to lack the requisites of strength and firmness so necessary in an appliance of this kind.

So, in the majority of cases, in the absence of some of the regulation time-tried approximation plates or rings, unless we are willing to assume the risks of the vegetable (potatoes) approximation plates of Dawbarn, we have to fall back upon resection and repair of the gut by circular enterorrhaphy, or lateral anastomosis by suture without anastomotic appliances. Robt. H. Weir reports (*vide Med. Record*, April 19th, 1892) one successful case by this method, where the ileum a short distance from its junction, was united to the sigmoid flexure for relief of a neoplastic intestinal obstruction, located in the transverse colon, thus throwing out of the bowels circuit the entire colonic tract. I am free to say that this method seems to have the advantage of simplicity of detail over that practiced by myself in the cases above reported.

Of this, however, I am fully convinced, viz., the general practitioner, or at least such of them as essay to do the surgical work of general practice as it presents, should be prepared to meet successfully the indications which arise in intestinal obstruction from injury or disease in man, by acquainting himself thoroughly with the improved technique of intestinal anastomosis, with or without the aid of some of the approximation rings or plates now in use, or that of resection and repair of the gut by circular enterorrhaphy.

PIGMENTATION OF THE SKIN CAUSED BY CHRYSAROBIN.

It is known that when chrysarobin ointment is used in the treatment of psoriasis the affected parts of the skin appear white, whilst the surrounding healthy skin appears yellowish-red. Campana examined portions of the skin microscopically and found that the pigmentation in the surrounding skin was caused by the deposit of numerous blackish-yellow particles of chrysarobin within and between the epithelial cells in the basic layer of the horny epidermis.

Society Reports.

MEDICO-CHIRURGICAL SOCIETY, OF LOUISVILLE.

Stated Meeting July 22nd, 1892.

The President, Dr. F. C. Simpson, in the Chair.

Dr. D. T. Smith: I would like to continue report of a few cases: First, the two children I exhibited at the last meeting of this Society suffering from a peculiar nerve trouble—their condition remains about the same.

Second, you will remember I brought before the Society about six months ago, a child with a tumor on the head. This afterward developed into what was supposed to be sarcoma, growing very rapidly. The patient was taken to the Children's Hospital and Dr. Cecil removed the growth. It had the appearance of sarcoma and was probably congenital. A few days after the operation the child died; no microscopical examination was ever made of the growth.

The third case is one that I presented to the Society about eighteen months ago, the patient having many symptoms of Renaud's disease, or symmetrical gangrene, but not a typical case by any means. The case has been progressing, and the patient is now suffering a good deal of pain, complains of cold and numb feelings about the spine, etc. She is very apprehensive that it will run to a fatal termination. She complains of pain especially between the shoulders, and a point about the lower one-third of the dorsal vertebræ is decidedly tender on pressure. The appetite is still fairly good, but the condition of weakness, pain, depression, coldness of the limbs, etc. mark the progress of the disease. Since she left me, she has been treated by a great many physicians and has undergone various kinds of treatment, none of which have been of any particular benefit. Now, she returns to my care, and I must confess that I know of no remedy that would be of advantage. I proposed electricity in this case with but little belief that it would do any good. I believe it is a degeneration of nerve cells in the brain and cord, just exactly what kind I am unable to say. No medication

she has used has done any perceptible good, one kind any more than another.

CONGENITAL CATARACT.

Dr. J. M. Ray: About a year ago I reported to this Society five cases of congenital cataract that I operated on in one family. These children were brought here to the blind school and originally fell into my hands. I operated upon all five by the needle operation. The oldest one, it seemed, had never been able to see at all. I did a pretty thorough operation on her and in a week afterward there was quite a rent through the lense, through which the light reached the retina, or partially so. I held my watch in front of her, and she would say it was very bright, although she did not know what it was. The other children had a little sight. The oldest child was about seventeen, youngest about seven years of age.

It is very curious that five children in the same family should be similarly affected. I noticed not long ago in some foreign medical journal a report in which the family history could be traced back through several generations; that is a tendency in the family to the development of cataract in several generations. It is impossible to trace this family history back that far, but I find that the father has cataract, completely blind in one eye and partially so in the other. He has a brother who has cataract, and this brother has a son who is also affected, and this is as far as I can trace it. It seems quite strange that they all were born with cataract.

Dr. S. G. Dabney: Dr. Ray's report is very interesting indeed; five cases of congenital cataract in the same family. It is remarkable to what an extent heredity influences certain diseases of the eye. A few years ago I reported to the Louisville Medical Society cases of retinitic pigmentosa occurring in four successive generations of the same family.

In regard to cataract—I had rather an odd experience recently: I saw a child about eight years old whose eye had been operated upon in the same manner as described by Dr. Ray. The mother had never been satisfied and thought the child had not received anything like the benefit from the operation that she ought; really it was because she had neglected to have the proper glass adjusted. I fitted it with a glass and the patient is now able to see very well. I operated upon the other eye for similar trouble, and have just about finished it now, with perfect result.

HEREDITABILITY OF RETINITIC PIGMENTOSA.

Dr. J. M. Ray: Concerning the hereditability of the disease—retinitic pigmentosa—it has been thought to be the result of consanguineous marriages, more than anything else. I saw a woman yesterday having acute glaucoma in one eye; I operated on her sister six months ago for the same trouble; the sister came to me at the college dispensary with absolute glaucoma having occurred primarily some years before. She had repeated attacks which led to complete blindness. At the time I saw her the eye was sightless and I advised her to have it removed as it was very painful. I prescribed eserine which gave her almost immediate relief. I was called to see her sister in consultation on Tuesday evening; found her suffering with acute glaucoma and advised an immediate operation. This was refused, and she said she wanted some of the drops like I gave her sister. I told her I thought she was losing valuable time; that an operation was demanded and that immediately. I gave her some of the drops, but they did not give the same relief as in the former case.

GLAUCOMA.

Dr. S. G. Dabney: An old gentleman came to me last fall from another city; he was led into my office by a boy about fifteen years old, and I took it for granted, of course, that the old fellow who was being led in was the patient. He said he was uneasy about the boy's eyes. He then gave me this history: He said he, himself, lost his sight about thirty years ago with glaucoma: that his oldest son when about eighteen years of age had lost his sight with glaucoma, and he believed the boy he had brought to me also had the disease. And he evidently did have a typical case. I gave him an unfavorable prognosis as the case was already chronic and of long standing, but advised that an operation be done at once. The old gentleman said he had had the operation of iridectomy performed on himself as well as on his oldest son, but both of them had lost the sight of both eyes. Nevertheless

I advised this operation as I thought it was the only chance. I think his intention was to see other oculists; do not know whether he did or not.

It was a remarkable instance of glaucoma occurring in three members of the family, also occurring in the two cases at such an early period in life.

Dr. D. T. Smith: In the matter of the influence of consanguineous marriages: This is a subject that I have taken considerable pains to investigate. At one time you know it was regarded as almost criminal to contract consanguineous marriages. There is no doubt that this feeling to a certain extent should exist, in order to prevent improper marriages. However, for the last several years, the fever has died out and I believe that justice is being done by thoughtful men on the subject. I think now it is universally accepted by men who are capable of deciding in matters of this kind, that marriages of blood relations, unless there are physiological reasons to the contrary, are entirely safe. We all know that great perfection in the development of extra qualities has been attained by in-and-in-breeding among the lower animals.

SARCOMA OF MAMMÆ.

Dr. T. H. Stucky: I simply want to continue report of a case: You will remember at a meeting of this Society several weeks ago, I read a paper on subject of sarcoma of the mammæ, in a girl thirteen years of age. One breast was removed on account of sarcomatous growth. The other breast is now becoming involved and will soon have to be removed.

CASE OF GALL STONE AND SUBSEQUENT MORPHINE POISONING FROM OVERDOSING.

Dr. D. T. Smith: A gentleman about thirty years of age came to my office stating that his health had been fairly good, with the exception that for a week he had had some pain in the epigastric region which lasted a short time at first, and would then return with more severity. He had a very unfavorable look about his face, nutrition seemed to be very much impaired, and I felt that the case was rather more serious than he seemed to anticipate. I prescribed an anodyne for him as he was suffering some pain; after a short time I was called to him and finding him in severe pain, prescribed four grains of morphine in a mixture of two ounces, with instructions to take a teaspoonful every half hour until he was relieved. This was about ten o'clock in the morning. About two or three o'clock in the afternoon I was again called to see the patient, the pain at this time was intense, and he was evidently passing gall stones. I gave him two doses of the mixture of morphine, and told him to remain in bed until he got relief. About seven o'clock that evening he became quiet; he had taken then about three grains of mophine—from ten o'clock in the morning until seven at night. He had also taken a little turpentine and ether, I believe one dose of each. He passed through the night very comfortably, using hot cloths the over seat of the pain. The next morning when I saw him he was breathing only about two and one-half or three to the minute, pupils were contracted, just as we would expect to find in morphine poisoning. This stupor came on only late at night. I used artificial breathing and after a short time left him; did not think the conditions justified any very great apprehension. About eleven o'clock that morning I saw him again and his condition was little better. About nine o'clock that night Dr. Anderson saw him with me and he was still in a partial stupor, slow breathing, delirium and a little fever, temperature 101.1-2° F. He again began to complain of pain in the region of the liver. The second morning the stupor was still present though not so marked. I knew that the effects of the morphine had entirely passed off, and believed it was some products of the liver that was producing the poisonous effects. After a week he was able to sit up and is now slowly recovering.

It was rather remarkable that this patient should have had symptoms so nearly resembling morphine poisoning. I had no doubt in the morning but the intense pain having passed off, it left a weakness which allowed the morphine to assert itself. The smallness of the pupils would seem to indicate this. We believed the stupor remaining after the effects of the morphine had passed off was due to absorption of some of the elements of the bile by the abraded surfaces of the ducts.

Dr. Wm. Bailey: I am not surprised that Dr. Smith thought the influence was due to morphine, and I am inclined to

believe that the symptoms were due to morphine, primarily at any rate. I do not think that the absorption of cholesterine would give a respiration of two and one-half or three to the minute. I am satisfied that in a person not accustomed to it, three grains of morphine is quite sufficient to account for the narcosis that was present. I think it can be established that while persons are suffering intensely with pain, such as characterizes the passage of gall-stone or gravel, they can bear a great deal opium without any evidence of opium narcosis; but suddenly being relieved of pain (which is a physiological antidote to opium) by the gall-stone passing into the duodenum or the gravel into the bladder, all the evidences or symptoms of opium poisoning will then develop. I think we should be extremely cautious about the amount of morphine we have ready for either absorption or for action when pain should terminate. I think oftentimes we are pushing and crowding a remedy up to that point that as long as pain exists it is safe, but when pain shall terminate by cessation or removal of the conditions, then that amount of opium given during the existence of pain becomes a dangerous element in its action.

I am well satisfied from the history of the case as given by Dr. Smith, if I may be allowed to criticise the case, that it was opium poisoning, at least primarily, the influence not being fully exerted until after the patient had gotten sufficient relief to go to sleep; until the conditions opposing the action of the morphine were removed, then the toxic influences were developed. Something in the late part of the case, of course, may have been due to the absorption or may be from the retention of the poison in the blood. But with a contracted pupil, with respiration of two and one-half or three to the minute and with the administration of three grains of morphine, I am irresistibly drawn to the conclusion that much of the manifestation was due to morphine, whatever may have developed, or whatever may have existed later on.

Dr. R. C. Chonault: I was going to say that I could reconcile the seeming differences between the two gentlemen: Everyone who is at all familiar with the administration of morphine or opium, knows the dangers of it—first the stimulating effects, then afterward the tendency of opium we all know is to lock up the secretions of the skin; therefore, the position taken by Dr. Smith and the position also taken by Dr. Bailey, in my mind, could be very well reconciled. The effect of opium stopping the secretions, which has a tendency to leave the patient in that condition so common as described by Dr. Smith in the last stages of this case, is satisfactory to my mind that there may have been some poison in the blood from the effects of the opium.

Dr. D. T. Smith: I believe that the condition of the pupil must have been due to the morphine. I think the depression was either produced or greatly influenced by it. The length of time (twenty-six hours) after the morphine had been stopped, and the delirium which lasted three days thereafter, showed that there was something in addition to the morphine.

HÆMORRHAGE AFTER TONSILLOTOMY.

T. Mark Hovell writes as follows in the *British Medical Journal*:

A girl, aged about 20, had her left tonsil excised at the Throat Hospital, and severe hæmorrhage ensued. The application of cold and astringents having failed to check the bleeding, pressure was resorted to, which controlled it for the time, but it recurred as soon as the pressure was removed.

As the case was beginning to assume a serious aspect, it was evident that something must be done to speedily stop the hæmorrhage. It occurred to me that the failure with astringents was due to their being improperly applied, and I therefore mixed one part of gallic acid with three parts of tannic acid, and after adding a few drops of water, kneaded the powder into a very stiff paste. Having rolled some of it into a ball about the size of a marble, I introduced it into the mouth on my left forefinger, and rubbed it firmly into the bleeding surface, at the same time making counter pressure from the outside with my right hand. As the result of this treatment the bleeding quickly ceased and did not recur.

I have since met with a few cases of hæmorrhage following tonsillotomy, and in each of them the bleeding has been quickly and easily stopped by the treatment I have above mentioned.

Selected Formulæ.

HEMICRANIA.

PASTILLES.

℞ Phenacetin.....3 grams.
Caffeine and Sod., Salicyl.....0.15 gram.
Quinine Hydrochlorate.....2 grams.
Morphine Hydrochlorate.....0.05 gram.
Saccharine.....0.01 "
Divide into 10 pastilles.—One per dose.

—*Schlutius.*

VAGINAL INJECTIONS.

Dr. Budin (Paris) uses the following formula:

℞ Mercur. corrosiv.....gr. iv.
Acid. tartaric.....gr. xv.
Sol. alcoholic indigo carmine (1:25).....gtt. j.
Sufficient for one quart of water.

Dr. Charpentier (Paris) employs the following solution:

℞ Cupri sulphat.....5 jiss.
Aquæ distillat.....f ʒ xxxij.

—*Formulaire Aide-Memoire de la Faculté Médecine de Paris.*

CYSTITIS IN WOMEN.

In cystitis in women (*Deutsche med. Wochenschrift*, No. 21, 1892) introduce a tampon into the vagina covered with the following salve:

℞ Camphorated lanolin.....30 grams.
Extract of belladonna.....2 "

OINTMENTS.

Dr. Wende (*Buff. Med. and Surg. Jour.*, January, 1892) lays down the following essentials for a good ointment basis:

1. *Proper Consistence.*—It must be soft, smooth and pliable, readily admitting of a uniform application.

2. *Homogeneity.*—It must be perfectly homogeneous, free from grittiness and irritating bodies.

3. *Durability.*—It must not show a tendency to change its physical and chemical peculiarities on exposure or long keeping.

4. *Miscibility.*—It must be capable of easily receiving the ingredients to be combined or incorporated.

5. *Power of Imbibition.*—It must be capable of absorbing liquids, especially water.

6. *Limitations of Temperature.*—It must have a melting-point somewhat higher than the temperature of the body. It must not liquefy.

7. *Inability to produce Irritation.*—It must be perfectly bland and neutral in reaction.—*N. Y. Med. Journal.*

AROMATIC LAXATIVE ESSENCE.

This is officinal in the Strasburgh Pharmacopœia. It is an excellent laxative:

℞ Black hellebore.....60 parts.
Jalap.....60 "
Scammony.....30 "
Canella.....12 "
Cloves.....12 "
Calamus.....12 "
Proof spirit.....750 "
Mix, and macerate the drugs in the spirit for eight days. Strain, express, and filter.

An excellent substitute for the above may be made by dissolving 1 part of resin of jalap in 9 parts of alcohol, and flavoring with a little oil of lemon and oil of bergamot.

HEPATIC COLIC.

Dr. Lemoine (*Revue Thérapeutique medico-chirurgicale*, November 1, 1891) uses the following methods in the treatment of hepatic colic. If vomiting is present he has recourse to ethereal solutions or those containing chloroform, as follows:

℞ Syrup of acacia.....fl. ʒiv.
Ether.....fl. ʒj.

Or:

℞ Chloroform.....Mxv.
Tincture of myrrh.....Mxv.
Mucilage of acacia.....fl. ʒj.
Syrup.....fl. ʒiijss.
A teaspoonful of either of these prescriptions every fifteen minutes.

If vomiting is a pressing symptom, it may be relieved by small pieces of ice and sedative drink, aiong with very small quantities of cold beef tea or milk. A turpentine stupe or other hot application may be applied to the abdomen, which should be covered with a rubber cloth to keep in the heat and moisture. Dry heat may be used instead of moist if desired. Liniments are without effect, and mustard plasters injure the skin, but prolonged and very hot baths are of service. The writer also uses the following suppositories:

℞ Extract of belladonna, Extract of opium, āā 1-3 gr.
Cacao butter.....5j.
Sufficient for one suppository.

Or:

℞ Extract of opium.....1-6th gr.
Cacao butter.....5j.
Sufficient for one suppository.

ANAL FISSURE.

ENEMA.

℞ Krameria extract..... 1 gram.
Glycerin..... 40 grams.
Water.....120 "
Inject every other morning.

—*Gallois.*

ILEO-COLITIS.

Van Goidtsnoven has obtained most satisfactory results from the following:

℞ Hydrarg. chlorid. mit.....gr. i.
Bismuth salicylat.....
Salol..... āā gr. xii. M.
Pulv. carbo ligni.....
Div. in chart, No. xii.
Sig.—One powder every four hours.

Antiseptic irrigation of the bowels is also to be employed.—*Southern Med. Record.*

TINCTURE OF GINGER AND PODOPHYLLUM.

The solubility of resina podophylli in tincture of ginger affords a ready and efficient method of administering this valuable drug in cases where the use of it has to be persisted in for any length of time. H. A. Hare, in "Practical Therapeutics," advises that the drug should be given dissolved in alcohol (1 grain of the resin to 1 dram of alcohol), which could then be dropped in suitable doses on a piece of lump sugar. But with this method the carminative and stomachic effects of the ginger are, of course, absent, and we therefore propose the following:

℞ Resinæ podophylli.....gr. jj.
Tinct. zingiberis.....fl. ʒ j.
M. et sig. Dose.—One teaspoonful in a glass of sweetened water on retiring.

MENTHOL IN ITCHING.

Dubrieulh recommends the following for itching:

℞ Menthol.....2 drachms.
Almond oil.....3 ounces.
Mix, and apply.

SURGICAL TREATMENT OF GASTRO-INTESTINAL CANCER.

John Lindsay Steven, in tne *British Medical Journal*, of April 23, 1892, reviews the history of this affection with the object of deciding the question as to when operations are advisable. He states that it may be admitted that cancer of the stomach can be successfully removed in some cases and the patient's life thereby prolonged. Pylorectomy, however, is still regarded as being in the experimental stage. The reason assigned why many of the cases are not presented for operation until late in the course of the disease, is that the affection often remains for a long time latent, that is, they do not exhibit symptoms which are sufficiently characteristic. As a rule, when the tumor becomes readily recognizable, the time for operation has passed. The question of adhesions is also an important one and quite difficult to decide previous to operation, although nourishing the patient per rectum and examining under an anæsthetic may, in some cases, enable the condition to be diagnosed. The use of effervescing powders for this purpose is not regarded favorably. The writer gives an account of twenty-six cases of gastro-intestinal cancer; in nineteen the stomach was affected. In sixteen out of these, secondary growths were present. The existence of secondary growths would not always be discovered by an exploratory laparotomy, on account of their concealed situation. The character of the tumor is of more importance in relation to malignancy than is the size. He concludes with the following expressions of personal opinion:

(1) In the present state of our kn owledge and diagnostic symptoms of gastric cancer the radical operation of pylorectomy can only be very rarely justifiable.

(2) As all radical operations, if there is to be the slightest chance of ultimate success, must be undertaken as early in the course of the disease as possible, any exploratory abdominal incision, made merely with a view of finding out whether the tumor is suitable for attempting removal, and not for the palliation of distressing symptoms, can only be justifiable if the patient can be assured with tolerable confidence that he will not be worse after the operation than he was before it.

(3) Gastro-enterostomy and other palliative surgical procedures are likely only to be undertaken in the later stages of the disease, as a means of relieving distressing symptoms, of rendering life more bearable, and of probably postponing the fatal issue, and they are in the highest degree justifiable in all suitable cases. Under such circumstances, at a comparatively late stage of the case, and under the pressure of great bodily suffering, an exploratory incision with a view to palliation is quite justifiable.—*Univ. Med. Mag.*

THE TREATMENT OF CHRONIC METRITIS AND ENDOMETRITIS.

A great deal has been written from time to time by gynæcologists both in this country and abroad regarding the treatment of chronic metritis and endometritis, and many methods have been held up to the profession in the light almost of specifics. Nevertheless, it must be admitted that however all-embracing our therapy of these diseases is, it cannot be said to have been brought to that state of perfection where nothing further is needed. What is specially desired is some efficient means which can be used without much trouble or the necessity of the skill of the specialist. Such a therapy seems offered by Dr. Hans Dörfler, in a recent issue of the *Münchener med. Wochenschrift.*

The method consists in an intrauterine cauterization by means of a chloride of zinc solution. This was originally brought forward by Dr. Rheinstädter, of Cologne. The solution used is one of equal parts of water and chloride of zinc. The surgical armamentarium that is necessary is most simple, consisting of a speculum, uterine sound, two aluminum applicators, and a bullet forceps or tenaculum; besides these only absorbent cotton and glycerine.

The patient is placed upon her back, with her limbs flexed, in the ordinary position for vaginal examinations, and after the introduction of the speculum, one of the applicators with a pledget of cotton wrapped around the end introduced into the uterine cavity to wipe out any secretion that may be present, and immediately afterwards the second applicator, similarly wrapped with cotton, but also soaked in the solution of chloride of zinc, is quickly introduced into the womb before the internal os closes, and left there for perhaps a minute. Immediately there will be noticed a different character of discharge flowing into the speculum, and

this should be carefully soaked up with absorbent cotton to prevent any cauterization of the abdominal walls. After the removal of the applicator and the douching of the vagina, and while the speculum is still in place, a tampon of cotton about the size of a walnut and soaked in glycerine is pushed up close to the mouth of the womb. The tampon should be supplied with a double silk thread eight or ten inches long, to facilitate its subsequent removal. The speculum is then withdrawn, and after the lapse of twelve to twenty-four hours the tampon is also removed by the patient by means of the thread.

The introduction of the applicator in patients who have borne children usually presents few or no difficulties, especially if it is was bent in the curve of the cervical canal. If in the case of nulliparæ a difficulty in passing the sound is encounted the cervix may be held with the bullet forceps or tenaculum, which will greatly facilitate the passage.

The pain caused by the cauterization is usually *nil*.

Rheinstädter performed the operation several thousand times without even having an unfavorable complication. It is well to inform the patient that for a day or two following the operation she may expect a copious discharge containing pus.

The cauterizations should be repeated weekly, or at most only twice a week, but should always be omitted five days before the expected appearance of the menstrual discharge, and for four days after the cessation of the discharge. Ten or twelve such applications usually result in a complete and permanent cure.

The cauterization acts upon the substance of the uterus as well as upon the uterine mucous membrane. The diseased mucous membrane must be fully *ad integrum* regenerated. Upon the substance of the uterus itself the cauterization not only increases the supply of blood, but stimulates more forcible contractions, whereby both absorption and tissue reconstruction are augumented.

The principle indications for the treatment consist in the presence of those unbearable nervous difficulties coupled with endometritis, abundant and weakening menorrhagias, exhausting leucorrhœa, and a condition of long standing sterility. Dörfler has used the method in quite a number of cases, in the majority of which he obtained a complete cure after six or eight operations, and twice after a single cauterization.

APHASIA.

Dr. Knoblauch reports an interesting case of disorder of the articulating capacity from cerebral disease. The patient, a child six years old, presented motor aphasia and right-sided hemiplegia following acute encephalitis, consequent upon scarlatinal nephritis. From the beginning of the aphasia, which was permanent, the patient was incapable of spontaneous speech, although he appreciated perfectly everything that was said to him. The curious part of the case was, that articulation was possible when the little patient attempted to sing familiar airs (*Centralblatt f. klinische Medicin*).

The report of this case recalls to the writer similar phenomena presented by a patient who came under her notice some years ago. With the exception of the attack to be related, the young woman was in perfect health, was highly intelligent and anxious to be cured of her affliction. About once a year, for a number of years, the patient was suddenly seized with an attack resembling very much that of catelepsy, from which she would emerge with complete aphasia. During the asphasic period, which sometimes extended over several months, the patient was able to attend her duties as a public singer, articulation being perfect in singing voice. The restoration of the voice would be observed after an attack of less severity than the one in which the voice was lost. In the interval between the seizures the voice was natural and the patient in good condition.

Book Reviews.

INTRODUCTION TO THE ANTISEPTIC TREATMENT OF WOUNDS: According to the method in use at Professor Bilroth's Clinic, Vienna. Arranged for Students and Physicians. Translated, with the author's permission, from the German of Dr. Victor R. V. Hacker, Assistant in the Bilroth Clinic, Professor of Surgery, Surgeon to the Allegmeine Polyclinic and the Erzh. Sophienspital, in Wien. By Surgeon-Captain C. R. Kilkelly, M. B., Army Medical Staff. London: Percival & Co. Philadelphia: P. Blakiston, Son, & Co., Price, $1.00.

This admirable little book is a most excellent exposition of the antiseptic treatment of wounds, and is worth many times its cost to any one engaged in surgical practise. In it we find articles on the general principles of the antiseptic treatment of wounds, preparations before the operation, procedure during the operation, special measures for laparotomy, dressing materials and their use, antiseptic dressing of wounds, and a list of firms (Vienna), where most of the important clinical dressings and apparatus can be obtained, with their cost.

It is a work that should be in every physician's library and in constant use.

AN EPITOMIZED REVIEW OF THE PRINCIPLES AND PRACTISE OF MARITIME SANITATION. By Joseph Holt, M. D., Former President of the Louisiana State Board of Health, 1884–1888. New Orleans: L. Graham & Son, 1892.

This pamphlet of nearly 100 octavo pages gives a considerable amount of sanitary information, especially relating to the maritime sanitation at the quarantine stations of the Mississippi river, below New Orleans. It contains thirteen plates illustrating various matters connected with disinfection.

TRANSACTIONS OF THE AMERICAN DERMATOLOGICAL ASSOCIATION AT ITS FIFTEENTH ANNUAL MEETING HELD AT WASHINGTON, D. C., ON THE 22nd, 23rd, 24th, AND 25th OF SEPTEMBER, 1891, IN CONNECTION WITH THE CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS. Official Report of the Proceedings by George Thomas Jackson, M. D., Secretary. New York, 1891.

These transactions contain besides the Address of the President and Committee Reports twenty-six papers on various topics of special interest to dermatologists, and various discussions connected therewith. It is a very creditable report.

Correspondence.

PEPSIN AND ALLIED PREPARATIONS.

Editor of THE MEDICAL AMD SURGICAL REPORTER:—I am told by the agents of pharmaceutical manufacturers that the use of pepsin and allied preparations is on the increase among physicians. In the aggregate this may be true, but there is another view to take of the matter. Since this remedial, or rather digestive agent has been so elegantly prepared by the pharmaceutists, many physicians have fallen into the habit of prescribing it to patients freely and frequently, when nothing but placebos are required. In my acquaintance, among those physicians who do not live in towns where there are drug stores, and who have to furnish their own remedies, many practitioners are giving less of the pepsin preparations. One physician said he prescribed many pounds of it four years ago, in one year, but now had entirely ceased using it, and relied upon common tonics and the natural source of pepsin for digestion.

A large majority of the staff of the Memphremagog Hospital Clinic are either giving or prescribing pepsin preparations in lesser quantities or none at all. In my own private practice I am giving pepsin less frequently than formerly. I find that it may be given for a few days with apparent good effect, but if long continued it weakens digestion, and seems to take the place of the natural product. I have found, by experiment, many of the preparations on sale in the shops inert and useless. Anybody can test the digestive properties of the different preparations on milk in a few minutes. None, of course, should be given that have become inert.

JOHN M. CURRIER, M. D.,
Newport, Vermont, Aug. 18, 1892.

PRURITUS VULVÆ.

The wash described below has been found useful by Dr. Bulloch, in cases of pruritus vulvæ:

℞ Aluminii nitras.....gr. xxiv.
Aquæ .....ʒ iv.
M. Sig.—Wash the parts once or twice a day, and use as a vaginal injection in the same way.

Periscope.

THERAPEUTICS.

HYDROGEN PEROXIDE IN MIXTURES.

Mr. F. X. Moerk was led to made some experiments in order to determine the nature of the decomposition which ensued in putting up the following prescription: Tr. ferri chlorid. 2 cc., glycerin, 8 cc., hydrogen peroxid. 24 cc. The results were laid before a pharmaceutical meeting of the Philadelphia College, and are given in a paper in the *Am. Jour. Pharm.* for March. It was found that in making the mixture an immediate deepening of color followed, the temperature rose from 29° to 64°, and a decided odor of aldehyde and acetic ether were apparent. It was found that the decomposing action was due to ferric chloride in the presence of the alcoholic tincture, the hydrogen peroxide being reduced and the alcohol oxidized, free oxygen passing off. The ferric salt was not at once reduced to the ferrous condition. Experiments on the iron salt led to those on others, of which may be noted potassium ferrocyanide, ferrous sulphate, stannous chloride and lead acetate, which all produced decomposition of the peroxide, with evolution of oxygen. Magnesium sulphate, zinc sulphate, copper sulphate, alum, and mercuric chloride did not produce decomposition in 24 hours, but the addition of a few drops of sodium hydrate liberated oxygen in the case of mercuric chloride and copper sulphate. With silver nitrate the action was slow in the absence of sodium hydrate, but then energetic. The results of these experiments lead to the practical conclusion that in prescribing and dispensing hydrogen peroxide, its ready decomposition must be remembered, and it will not do to make desirable combinations unless experiments prove them to be practicable.

THE TREATMENT OF CANCER.

Under this head Dr. G. Sims Woodhead, in the Morton lecture on the ætiology of "Cancer," says: "From a careful microscopical examination of many hundreds of cancers that have been submitted to me for examination, I am firmly of the opinion that many surgeons make the mistake of not removing sufficiently freely either the tissues in which a cancerous growth has made its appearance or the lymphatic glands associated with it. Quite recently Mr. Harold Stiles, of Edinburgh, has carried on an extensive and careful investigation of how far the immediate tissues around the naked-eye cancer of the breast are affected. His method is based on the effect which nitric acid has upon the tissues, causing the connective tissue to become clearly differentiated from the epithelium. From a careful study of sections so prepared, both by Mr. Stiles and myself, as well as from microscopical examination, I am convinced that the only safe rule to be observed in removing cancer of the breast is to remove not only the main mass of the gland, but all outlying portions of the glandular tissue; so that if, on cutting away the margins of the tumor, treating with methylated spirit and nitric acid, and then with water, any opaque columns or fragments are to be seen, I should consider that the removal had not been free enough. Of course, the part of the tumor that should be especially examined in such a case is that near the sternum, where, by reason of the shape of incision usually adopted, there is the greatest danger of fragments of the gland being left."—*Maryland Medical Journal.*

THE PHYSIOLOGICAL ACTION OF ABDOMINAL MASSAGE.

Dr. Victor Eltz, having studied the contributions of Reibmayer and Nothnagel, believes that the action of massage in chronic intestinal catarrh depends upon the resorption of the infiltration of the wall of the intestine. In this view massage does not meet the indication of one symptom, but rather attacks the cause itself. The indications for the several methods for evacuation are: 1. For simple clearing of the bowels, *e. g.*, intestinal stenosis, internal purgatives. 2. For congenital hypoplasia of the muscular structures of the intestine, especially of the large intestine, irrigation. 3. In constipation, in general weakness, gymnastics, especially when lack of exercise is the cause. 4. Massage is indicated in—(*a*) true habitual constipation; (*b*) chronic intestinal catarrh (equally whether accompanied by diarrhœa or atony).—*Wiener klinische Wochenschrift*, 1892, No. 15, S. 221.—*Amer. Jour. Med. Sci.*

TREATMENT OF MORPHINISM.

Obersteiner individualizes strictly in the treatment of the morphine habit. Beginning with the average daily dose, he withdraws it as rapidly as the patient can stand it. When the dose has been reduced to a few centigrammes caution is necessary, as even a slight reduction is then badly borne. At this stage warm baths of from 5 to 15 min. duration, followed if necessary by the cold shower or cold pack for one-half to two hours at a temperature of 77° to 86° F., are often of benefit. Alcohol in liberal quantities often gives relief. Cocaine has no other use than to modify the symptoms and should only be used when these become violent, say 24 to 48 hours after the last dose of morphine. It is always given by mouth in doses of 0.05 to 0.1 gm., never exceeding 0.5 gm. per day. It should be reduced in a few days and never continued longer than 5 or 6 days. Nutrition must be improved by all possible means. If collapse occurs, morphine must be resorted to. Patients with cardiac troubles should not be subjected to complete withdrawal.—*Wien. Med. Presse,* No. 48, 1891.

INJECTIONS OF AMMONIO-CITRATE OF IRON IN CHLOROSIS.

Dr. Alvazzi, of Turin, has successfullly treated chlorosis by means of injections of ammonio-citrate of iron. For three months various preparations of iron had been given in considerable doses without benefit, and the patient had became so weak as to be unable to leave her bed. The red corpuscles, which were pale, averaged 4,000,000, per cubic millimetre, and there was slight leucocytosis. As the internal administration of iron had failed, it was determined to try injections of the ammonio-citrate according to the following formula: Ammonio-citrate of iron, grains 17; distilled water and laurel water, one and a quarter drachms each. The injections were given with an ordinary Pravaz's syringe. One-sixth of a grain of the salt was given once a day, the amount being gradually increased till on the ninth day it had reached two grains, still given in one injection. On the sixteenth day, no ill effects having been observod, two injections of two grains each were given each day, and after thirty days the patient was discharged cured. Two or three of the injections were given under the skin, but this having on each occasion caused severe pain, all the others were made into the substance of muscles. The injections were given with strict antiseptic precautions, and were always followed by somewhat vigorous and prolonged massage at at the seat of the injection. Pain seldom lasted long, and no abscesses or even swelling followed the injections nor did the temperature rise. When discharged, the red corpuscles had recovered their natural color, and averaged 4,350,000 per cubic millimetre, and the proportion of white corpuscles was normal. The hæmoglobin had risen from thirty-five to over ninety-five and the girl's weight increased from 72 to 84 pounds. Her appearance and general health had improved immensely.

TYPHOID FEVER SUCCESSFULLY TREATED WITH FEL BOVIS.

Dr. Adolph Zeh, after an extended use of the various antipyretics and intestinal antiseptics, reports favorably upon the use of this remedy in ten cases. He empties the alimentary canal by a sufficiently large dose of calomel, if the case is seen clearly; stimulates at once, preferably with whiskey; uses strychnine, caffeine, ammonia, camphor, and small doses of quinine; as a beverage, dilute nitro-muriatic acid in a large quantity of water, and fel bovis purificatum siccum in doses of two to four grains from three to six times daily in capsules. A liquid diet—milk, beef-tea, gruel, beef extracts or meat juices—is insisted upon.—*Merck's Bulletin*, 1892, No. 2, p. 83.

NEW CONTRIBUTIONS TO THE THERAPY OF MALE IMPOTENCE.

Dr. Victor v. Gyurkovechky has seen improvement in five cases of paralytic impotence, although only temporarily, from suspension. In three cases of sexual neurasthenia complete and satisfactory cures resulted. Suspension of healthy males was always followed by increased sexual desire. He also believes that hypnotism will be found a powerful therapeutic agent in the treatment of onanism, spermatorrhœa and various forms of impotence, and relates several cases to fortify his position. He also banished troublesome and constant erotic dreams in a single lady of 20 by this means, at the sixth seance.—*Wien. Med. Presse*, No. 47, 1891.

STYRONE IN MIDDLE EAR SUPPURATION.

A 1 to 5 per cent. solution of styrone (which is a compound of styrax and balsam of Peru) in alcohol is recommended in chronic inflammation of the middle ear. Dr. Spalding recommends it as specially useful in perforations of Shrapnell's membrane. He applies it on a small cotton swab after having had the ear thoroughly cleansed by syringing, and from results obtained he thinks that it merits a trial.—*Archives of Otology*, July, 1891.

THIOPHEN.

An unsigned paper in the *Revue de Thérapeutique Générale et Thermale*, 1892, No. 5, p. 70, gives an excellent *résumé* of this subject. Thiophen is a hydro-carbon of the aromatic series, a colorless, limpid oil, of faint odor, and miscible with water in all proportions, having as its symbol C_4H_4S. Spiegler has used the thiosulphate of soda ($C_4H_3CNaS_3$) and the iodide of thiophen ($C_4H_2I_2S$). The soda salt is a white powder, precipitated in the form of scales, contains 33 per cent. of sulphur, of a disagreeable odor which is usually not marked when in a 5 or 10 per cent. ointment. In prurigo complicated by eczema it can replace naphthol. The biniodide has been used as a substitute for iodoform. It crystallizes in beautiful plates, insoluble in water, but very soluble in ether, alcohol and chloroform. Its odor is characteristic, but not disagreeable; gauze impregnated in a proportion of 10 per cent. emits a slight odor, rather agreeable and aromatic. This salt, in the laboratory, will prevent the development of the *staphyloccus aureus*. In burns even to the third degree; so far as preventing odor and desiccation, it is superior to iodoform. Hock has used it in various conditions, phlegmon, contused wounds, lacerations, compound fractures, mastisis, onychia, and caries, with very satisfactory results. There seems to be no poisonous action; it does not give rise to eczema, it even seems to cure it when existing. Applied as a powder it is a vigorous disinfectant, and may even give rise to a burning sensation which may persist for half an hour. It will deodorize more energetically than iodoform, but it is a less active stimulant of granulation-tissue.—*Amer. Jour. Med. Sci.*

MERCURIAL OINTMENT IN INTERSTITIAL KERATITIS.

Mitvalsky (*Centralbl. f. prakt. Augenheilk.*, February, 1892) strongly recommends the use of an ointment composed of mercurial ointment 1 part, vaseline 2 parts, lanoline 1 part, in cases of parenchymatous keratitis, etc., as a valuable means of shortening the duration of the attack and clearing up the opacity of the corneal tissue. He has employed this for the last three years, and from his experience in more than 100 cases feels enabled to speak very encouragingly of its effect. Having tried the ordinary blue ointment and having found that it gave rise to too much irritation of the conjunctiva, he advises a more dilute preparation made according to the above formula. The ointment should be placed in the conjunctival sac, and rubbed in gently with the finger placed over the eyelid. It should not be used in cases with marked ciliary injection.—*Brit. Med. Jour.*

THE USE OF ELECTRICITY IN CHRONIC AFFECTIONS OF THE MIDDLE EAR.

Baxter (*Arch. of Otol.*, xx, 3) reports ten cases of disease of the middle ear treated by the constant current. He thinks that when improvement takes place it is most noticeable in the increased ability to understand speech, the tinnitus is lessened, the feeling of pressure, fullness, and dullness are lessened or removed. The method of application is as follows: After placing the patient with the head inclined the external auditory canal is filled with warm water, the aural electrode (a small wire insulated to within two millimeters of its point) is introduced into the auditory canal and retained there by the fingers of one hand, leaving the other hand free to manipulate the switch, rheostat, and pole-changer; the other electrode, covered by a sponge, is held in the patient's hand. The current is then switched on and gradually increased, watching the milliampèremeter until from five to ten milliampères of current are passing through the parts; then, retaining the electrodes in position, the poles are changed two or three times a minute. From three to six minutes suffice for an application. The ear is then dried and the patient kept quiet for a short time to recover from any possible vertigo.

THE PEROXIDE OF HYDROGEN IN PURULENT CAVITIES AND FISTULÆ

Dr. Graff (*Med. Neuigkeiten*, No. 2, 1892) has used this drug in cases where a complete opening of the fistula or abscess is impossible. Here irrigation with the peroxide has an excellent action, superior to that of the other antiseptics. The great formation of gas which follows the contact of the antiseptic with pus or blood permits the pus to be removed very thoroughly. If then an antiseptic bandage be applied healing takes place very rapidly. If, in cachetic individuals, the granulations are weak and slow in growth, one may alternate with injections of equal parts of ether and balsam of Peru. This procedure is of great value in suppurating cavities with indurated edges, as, for example, in the separation of sequestra. The remedy has also been used with success in dacrocystitis and purulent conjunctivitis. Where the drug in injected into cavities one must see that there is free exit for the gas, which quickly forms; otherwise the pressure might cause trouble, as for example, after opening cerebral abscesses, injection of pleural fistula, etc.

SUBCUTANEOUS INJECTION OF SALT SOLUTION IN DIARRHŒAL COLLAPSE.

Demieville recommends the subcutaneous injection of sterilized salt solution in the collapse produced by acute gastro-enteritis in infants. The apparatus required is simple. The salt solution used is a solution of chloride of sodium (0.6 per cent.) As the solution is rapidly cooled by passing through the tubing, it is well to employ a large reservoir, and to be sure that the solution as it leaves the needle is warm. The skin must be thoroughly disinfected, and also the needle and apparatus; the water should be boiled before use.

As to the quantity to be used, a case is related in which a child, aged four and one-half months, received about four ounces; the injections were made into the thighs, and were followed by gentle massage. The patient in the case mentioned appeared to be *in extremis* when the injections were given, but began to improve almost at once, and reaction was established in a few hours. The injection made the child cry, but did not seem to cause much suffering. The good results obtained by this method are believed to be due to the improvement produced in the circulation, especially in that of the nervous centres.

HYPNOTISM IN THE PSYCHOSES.

Dr. J. Luys states (*Jour. de Med, de Paris*, Mch. 20, 1892) that in the acute periods of insanity, in lucid intervals, and in latent hysteria, nothing is better than hypnotism. Certain paretic dements with quiet hypomania are fascinated and calmed by a bright object. Rotatory mirrors calm and sooth them so that they fall asleep. They awaken from the artificial slumber refreshed and invigorated mentally and physically. In acute hysterical hallucinatory insanity in young girls, the patients are plunged rapidiy into slumber, and such slumbers decrease the period of convalescence.

TINCTURE OF IODINE IN CORNEAL ULCERATIONS

In 1891 Dr. Chibret published a method of treating certain forms of ulceration of the cornea by means of tincture of iodine, which he regards at possessing powerful antiseptic properties and energetic dialytic powers; as being free from liability to precipitate insoluble saline compounds, leaving indelible opacities in the cornea; and lastly as having no destructive properties on the cornea. He thinks it may be applied by means of a little roll of cotton wool to the surface of the ulcer, and that the application should be made once or twice daily. Such treatment prevents, he believes, the staphylomata that are apt to form after the cicatrization of large ulcers. M. Sedan, in a subsequent communication, states that several years ago, finding some forms of ulcers of the cornea rebellious to ordinary treatment, he adopted the plan of touching the ulcerated surface, first lightly and then more freely, with tincture of iodine. He found however that it was objectionable because it was painful; because—however carefully applied—it rapidly distributed itself over the urface of the cornea; and lastly, because it formed deposits in the inferior *cul-de-sac* of the conjunctiva. It also has a tendency to produce ciliary blepharitis. If however, some good menstrum could be found, it seems that it might sometimes prove serviceable.—*Recueil d'Ophthalm.* p. 710, 1891.

PERMANGANATE OF POTASSIUM IN THE TREATMENT OF DIPHTHERIA.

Bowman reports several cases of diphtheria in which most excellent results were obtained by the use of a solution of permanganate of potash of the strength of theee grains to the ounce. Three or four applications an hour were made directly to the membrane with a large camel's-hair brush for eight or twelve hours. After this once every two to six hours is sufficient. In some cases a spray is a better method of application.

THE TREATMENT OF HYPERTROPHIED TONSILS.

Knight (*Jour. Am. Med. Assn*, 1891, xvii., 537.) states that the treatment of enlarged tonsils may be divided into medical and surgical. The former may be dismissed in a few words, since clinical experience shows that the hypertrophied tonsil yields slowly, if at all, to internal medication, except, perhaps, in struma or anæmia. In such cases hygiene, diet and tonics may have a limited influence. The same is true of local applications resorted to for the purpose of promoting absorption.

The following enumeration includes most of the methods which have been or continue to be practiced. Some of them have long since been abandoned, while others have never found favor except in the hands of their promoters: 1. Electrolysis. 2. Massage. 3. Chemical caustics. 4. Galvano-cautery puncture or ignipuncture. 5. Avulsion with forceps. 6. Ligation. 7. Enucleation by means of the finger. 8. The cold wire snare. 9. The galvano-cautery snare or amygdelotome. 10. Excision by means of scissors, the bistoury, or the guillotine.

In the large majority of cases, excision is the operation of choice. In tractable cases the knife may be used with safety, but it is difficult to see that it has any advantage over the guillotine. The latter. if properly handled, will give an equally good result, and is undoubtedly safer. The extirpation of the tonsil should be made as radical as possible for two reasons: 1. Tendency to recrudescence is lessened. 2. Danger of hæmorrhage is diminished.

There is no question that Mackenzie's modification of Phynik's well-known guillotine is incomparably superior to all other instruments. The addition of a fork to the guillotine not only complicates the operation, but adds to the difficulty of keeping the iustrument aseptic. This instrument commends itself because of its strength, its simplicity, its safety and its effectiveness.

There no doubt exists some prejudice against the use of an anæsthetic in removing tonsils. Avoid profound anæsthesia, remove the tonsils in quick succession, immediately turn the patient upon the face, and fatal asphyxia cannot occur. In young children we should use ether or chloroform, not only to obviate mental and physical suffering, but, what is much more important, to enable us to explore the naso-pharynx at leisure, and if necessary to remove from that region those collections of lymphoid hypertrophy so often associated with similar overgrowths between the palatine folds.

A CASE OF PULMONARY GANGRENE TREATED BY ANTISEPTIC INHALATIONS AND THEN BY SURGICAL INTERFERENCE.

M. M. Constantin Paul and Ch. Perier, (*Bulletin de l' Academie de Medicine*, March 15, 1892) gives the following account of a case:

MD., æt. 58, was seized with a severe bronchitis, his expectoration soon becoming fetid. On examination a focus was found on the left side posteriorly, marked by very fine râles. The disease progressed and symptoms of gangrenous septicæmia developed, with chills, cold sweats, diarrhœa and prostration. Antisepsis of the air-passages was then practiced by passing the breathed air through a saturated solution of carbolic acid. Dr. Paul had previously cured fourteen cases in this way. In this case the septic symptoms rapidly disappeared. The sputum continued to be abundant, but lost its fetid character. The patient recovered sufficiently to attend to his business. An area without respiration remained at the site of the lesion. A month later the symptoms returned, and again the same treatment succeeded. Nearly a month later another relapse occurred and about 300 g. of fetid pus was coughed up at once. Similar relapse recurred at intervals for many months. Signs of a cavity developed at affected spot and the urine contained sugar. Dr. Perier was now called in and confirmed the diagnosis. An opening was

made between the clavicle and mamma, the healthy lung tissue punctured with a trocar and a cavity with viscid pus discovered at a depth of one-half inch. After carefully cleansing the cavity drainage tubes were introduced. A perfect recovery resulted.—*Univ. Med. Mag.*

PARALYTIC OBSTRUCTION OF THE INTESTINE RELIEVED BY THE CONSTANT CURRENT.

Semmola (*Internationale klin. Rundschau*, 1892, No. 16, p. 641) has reported the case of a man, twenty years old, of nervous temperament, in whom, after the occurrence of dirrhœa, symptoms of intestinal obstruction appeared; to these ischuria was added. Ordinary treatment was without avail, and celiotomy was proposed. From the suddenness of the onset of the symptoms of obstruction after the occurrence of diarrhœa; from the paroxysmal character of the pain; from coexistence of paralysis of the bladder, without previous disease; and from the neuropathic tendency of the patient, a diagnosis of paralysis of the bowel was made, and the application of the constant current was recommended. The positive pole, attached to a catheter, was introduced into the rectum, and the negative pole stroked upon the abdomen in the course of the colon. The applications were made for from eight to ten minutes thrice daily. The symptoms gradually improved, and, after the ninth application, the bowels were spontaneously moved. In the course of ten days the patient was completely restored to health.—*News.*

MEDICINE.

CRANIAL AUSCULTATION.

In cases of vertigo associated with noises in the head, Dr. B. Ward Richardson is in the habit of auscultating the cranium (cranial auscultation) over the mastoids. When the sound is associated with cardiac murmur the bruit may be traced up the carotids and heard over the mastoids. This is increased on lying down. In cases where associated with anæmia a soft murmur may be heard, which is continuous with the first sound of the heart. It is increased on exertion; and when the heart is excited, as from the use of stimulants, a sound similar to the venous hum may be heard.

It is important to make such an examination before concluding that the noises are due to disease of the labyrinth. —*Asclepiad*, October, 1891.

REICHMANN'S DISEASE.

Mathieu (*Arch. Gén. de Méd.*, May, 1892) relates the following case of permanent gastric hypersecretion followed by ulcer. A man, aged forty-two, dated his dyspeptic troubles from a reverse of fortune due to the Russo-Turkish war. He suffered from attacks of pain, typical of gastric hypersecretion, commencing about a couple of hours after food, and increasing for another two or three hours. The pain was often relieved by taking a little food, either solid or liquid. Sometimes vomiting put an end to the attack (see also "Epitome," March 5, 1892, par. 199). Four years ago he was much benefited by washing out the stomach. On admission there was marked gastric dilatation. The gastric juice contained an excess of hydrochloric acid. He was much improved by treatment, and was thinking of leaving the hospital, when he was seized one evening with pain in the epigastrium. He died in two days' time of collapse. At the necropsy the stomach was much dilated and placed almost vertically, so that the greater curvature lay in great measure in the left mammary line, the lower part of the stomach near the pylorus being greatly distended, whereas the pylorus itself was nearly in the usual position. On the anterior surface, about two centimetres from the pylorus, there was a perforation big enough to admit the tip of the index finger. It had obviously been there some time. There was some general peritonitis, but apparently none of the contents of the stomach had extravasated, owing to the position of the perforation. Sections from the cardia showed that the coats of the stomach were thickened and the glands hypertrophied. In the region of the dilatation near the pylorus, the changes in the mucosa were more marked. There was round-celled infiltration and the glands were dilated and cystic. In all cases of permanent hypersecretion there is gastric dilatation. It is evident that hypersecretion is compatible with a considerable amount of gastritis. The parts least affected secrete the gastric juice; those most diseased are digested.

The round ulcer is one of the dangers of gastric hypersecretion, and for this reason passing the tube and washing out the stomach must be used prudently.—*British Medical Journal.*

ADDISON'S DISEASE WITHOUT SUPRA-RENAL CAPSULAR LESION.

Dr. M. Raymond has had under care a 27-year-old woman, who had the first symptoms of Addison's disease early in Jan., 1891 (*Prog. Med.*, Mch. 19, 1892). She died in May, 1891. The supra-renal capsules on autopsy were found healthy. The right semi-lunar ganglion was sclerotic, the nerve-cells were pigmented, vacuolized and thinned; some of them were atrophied. The cord was healthy. In Raymond's opinion this case is additional evidenece in favor of the belief that Addison's disease is a neurosis.

ON SOME NON-VALVULAR HEART MURMURS.

This was the subject of a paper read before the Amer. Med. Assoc. by Dr. N. S. Davis, Jr., of Chicago, (*Ex*). Non-valvular heart-murmurs may give the same physical signs as valvular ones, the same changes also in the size and position of the heart. Not infrequently we have cough, dyspnœa, vascular disturbances, œdema, urinary changes, etc. He related the histories of several cases in which the autopsy showed the cause of the murmurs to be old and tenacious decolorized clots in the ventricles and entangled among the chordæ tendinæ. In one case there was an old calcified plate of connective tissue (the result of a former pericarditis) in the pericardium. The murmur in this latter instance was propably due to irregular muscular contractions in the ventricular walls, causing various eddies in the blood-current. Anæmia also caused murmurs not distinguishable in their physical characteristics from those of valvular lesions.

RELAPSES IN GRANULAR INFLAMMATION OF THE CONJUNCTIVA.

Galezowski (*Soc. de Chir.*, February, 1892) has been struck with the extreme frequency of relapses in granular disease of the conjunctiva, and believes that the cause resides in lesions of the lachrymal ducts which complicate the granular conjunctivitis. These lesions, which exist ninety times in one hundred, are either obstructions or contractions of the lachrymal ducts. If the latter are not treated, the reproduction of the granulations of the conjunctiva is rapid.—*Ther. Gaz.*

HÆMORRHAGES INTO THE LABYRINTH IN CONSEQUENCE OF ANÆMIA.

Dr. J. Habermann, of Prague, reports (*Archiv f. Ohrenheilk.*, vol. xxxii. p. 82), two cases of hæmorrhage into the labyrinth, one in consequence of pernicious anæmia, the other is consequence of simple anæmia. In the first instance, the patient was a young servant girl, twenty-one years old. Post-mortem, among other conditions, revealed hæmorrhages into the meninges, brain, pharynx, pericardium, and small intestine, but none in the retinæ. An examination of the right auditory organ revealed neither micro- nor macroscopic changes in the middle ear. In the cochlea, however, there was a small hæmorrhage in the upper end of the ligamentum spirale, in the region of the anterior periphery of the basal whorl, of the scala vestibuli, and a somewhat larger one in the basal whorl in the upper half of the canalis ganglionaris. Here the blood was between nerve-fibres and the ganglion cells. Extensive hæmorrhages were found in the vestibule in the semi-circular canals; also between the ligaments of the utriculus, on the posterior wall, and on the outer wall, near the posterior edge of the stapes (oval window). Copious hæmorrhage also had occurred near the mouth of the aquæductus vestibuli, and in the external semicircular canal. The extravasation of the blood was supposed to be due to diapedesis. The deafness and tinnitus aurium complained of during life was referred to the hæmorrhages. The vertigo could have been due to the simultaneous lesion in the brain.

The second case of labyrinth-hæmorrhage, the result of simple anæmia, occurred in a young woman twenty years old. In this patient there ensued hæmorrhages into the stomach, the intestines, and then retina. Finally, there occurred hardness of hearing, tinnitus aurium, and, at times vertigo. Treatment of the anæmia was followed by improvement in hearing.—*Amer. Jour. Méd. Sci.*

TWO CASES OF URTICARIA FACTITIA.

Conrad Alt describes two cases of this very interesting phenomenon. One, a girl of 12 years of age, had suffered from motor and sensory paraplegia of the lower extremities. She had completely recovered, but during the course of treatment she possessed the symptoms of urticaria factitia. This condition; which has long been known, described by Bateman in 1821, and more particularly by Dujardin-Beaumetz, consists in a raising of the skin after stroking heavily with the nail. In this manner figures of any description can be made to appear on the skin in swollen and reddened lines.

Another case, aged 20 years, is also reported, in which this condition lasted nearly three years, and was most remarkable in its intensity. Uticaria factitia is found especially in hysteria, neurasthenia and epilepsy.

SARCOMA OF THE URETHRA.

Ehrendorfer (*Centralb. f. Gynäk.*, No. 17, 1892) reports a case of this rare disease. As in Beigel's case, the patient was about 50 years of age; the tumor was a small round-celled sarcoma, forming fleshy wattles in the anterior part of the vulva. Ehrendorfer's patient had noticed a swelling for about eighteen months before admission into the hospital. A watery, sanious, odorless discharge escaped from the tumor, which caused pain during connection. The growths (three in number) pushed the labia aside, and rose high, like cock's combs, running from before backwards; each measured about one inch in length. They surrounded the meatus urinarius. The vagina was slightly prolapsed, the uterus atrophied. The sarcoma was removed on October 29th, 1891. The patient refused to take any anæsthetic. The entire tumor was drawn down with the fingers, and its pedicle, consisting of the mucous membrane of the urethra, cut through. The divided borders of mucosa were united with catgut sutures after a spouting artery had been secured. The parts were dressed with iodoform powder and gauze; the urine was drawn off for a time by means of a soft catheter. The wound had healed at the end of the fourth week. The patient has not been heard of since her discharge.—*Brit. Med. Jour.*

PERFORATIVE AORTITIS.

Oliver (*Lancet*, No. 3558, p. 1033) has recorded the case of a man, age thirty-six years, who thirteen years previously had an aggravated attack of rheumatic fever. Murmurs indicative of the existence of aortic obstruction and incompetency, of mitral incompetency, and of pericarditis were heard and the heart was hypertrophied. Some time later the patient rather suddenly died. At the autopsy, the pericardium was found occupied by a clot entirely surrounding the heart. The heart itself was dilated and hypertrophied. The mitral orifice was dilated, the valves normal. The aortic valves were incompetent. The aorta, just beyond it origin, presented a pouch-like dilatation. Over a small area between the mouths of the coronary arteries, extending upwards about an inch and a half, the lining membrane of the aorta was red, softened, and ulcerated, and in two places gangrenous. From the center of this area a small pouch bulged outward. The walls of the pouch were thin and soft, and perforated at its base by an opening as large as the head of a pin. An atheromatous plate lay close to orifice of the coronary artery. Microscopic examination confirmed the macroscopic evidences of the existence of an ulcerative aortitis, and disclosed in addition the presence at the focus of inflammation of considerable numbers of bacilli resembling those of anthrax. There was no history or knowledge of infection.

THE TREATMENT OF EPILEPSY.

Dr. G. Hinsdale gives his experience in the use of potassium bromide, magnesium bromide, nitro-glycerine, antifebrin and sulfonal. Potassium bromide, he used in 12 cases. The result was satisfactory in one, doubtful in five, unsatisfactory in six. As it is an intestinal irritant and lowers the pulse and depresses the heart, it is not considered a valuable remedy to use. Magnesium bromide exerts an undue power in controlling epileptic attacks, but it is more liable to produce facial eruptions than the other bromides. Nitro-glycerine failed in results. Nitrate of potassium has not been satisfactory. Antifebrin has temporary beneficial results, but it soon lost its power. Sulfonal was unsatisfactory.—*International Medical Magazine*, March, 1892.

THE SYMPTOMATIC VALUE OF THE PULSATIONS NOTICED IN THE EAR BY THE ENDOTOSCOPE.

Gellé (*Ann. des. mal. de l'oreille et du larynx*, xvii, 9) draws the following conclusions from his observations: By the aid of the endotoscope the state of the circulation of the blood in the tympanic cavity can be studied; in active congestion of the tympanic mucous membrane this instrument shows pulsations isochronous with the pulse. This demonstration is especially useful when the objective symptoms are wanting. The pulsations of the endotoscope actually show the activity of the inflammatory process in the middle ear. They disappear when the process declines, but persist as long as the abnormal vascularity lasts. Their absence in certain cases of subjective affections of congestive appearance enable us to localize the seat of the exudation in the deeper parts of the organ, or to recognize the purely nervous origin of the phenomena.

OSTEO-ARTHROPATHY OF PULMONARY ORIGIN.

Orillard (*Rev. de Méd.*, March, 1892) relates a case of this disease first described by P. Marie. A man, aged 56, dated the beginning of his illness from the time he had his chest rather severely squeezed fifteen months previously. He had suffered from cough with some blood in the expectoration for the past eight months, and from severe pain in the lower part of the chest for five months, at which time he noticed that his finger ends began to enlarge. On admission, some dullness and deficiency of breath sounds were noted at the right base behind. The chest was deformed, there being an antero-posterior as well as a lateral curvature of the spine in the dorsal region. Several times in the day the skin became the seat of a very transient eruption resembling urticaria. In the right elbow joint (which had some years previously been injured but had quite recovered) the movement became limited. The hands presented the characteristic deformity. The terminal phalanx of each digit was much enlarged, the bone being chiefly involved. The nail assumed the shape of a parrot's beak. The same changes were noted in the feet. The knee-joints were also enlarged and somewhat fixed when the patient was standing. The bones of the head and face were unaffected. Later the right chest had to be tapped several times, and ultimately the patient died. At the necropsy a considerable effusion was found in the right pleural cavity, the lung being collapsed, and the pleura adherent over the seventh and eighth dorsal vertebræ. The liver was pushed down. A puriform mass occupied the body of the seventh vertebra and adjacent part of the parenchyma of the lung. The left lung contained cretaceous tubercle in the apex but was otherwise healthy. The case differed from acromegaly in that the face and head were unaffected, and in the character of the change in the hands. The relation between the lesions was the following: (1) a chronic pleurisy secondary to the disease in the vertebra (this latter producing a pachymeningitis involving the sixth, seventh, and eighth nerves, and hence the pain) and (2) consecutive osteo-articular deformities.—*Brit. Med. Jour.*

ASSOCIATION OF TABES WITH SACCHARINE DIABETES.

By Guinon and Souques (*Archives de Neurologie*, 1891, January and March, 1892).—The following conclusions are drawn by these writers on this question of the relationship of tabes and diabetes:—

1. There exist cases of association of true tabes with undoubted saccharine diabetes.

2. This association of tabes with diabetes in one and the same individual as in one and the same family, is not a fortuitous coincidence. It is the consequence of the intimate bonds of relationship which unite the two great families, the arthritic and neuropathic in general, diabetes and ataxia in particular.

3. To establish the diagnosis of these cases of association, and to separate them from diabetic pseudo-tabes, and from tabetic glycosuria with which they may be confounded, it is necessary to proceed in the following manner:—In case of an undoubted diabetic presenting tabetiform nervous signs, if the antidiabetic treatment brings about an amendment of these nervous signs along with improvement in the diabetes, pseudo-tabes may be affirmed, but if the contrary happen the presumption is in favor of true tabes, and the existence of subsequent appearance of certain tabetic signs (inco-ordination, vesical and

ocular troubles) transforms this presumption into a certainty. In the case of an undoubted tabetic, on the other hand, whose urine contains sugar, if the glycosuria is accompanied by anæsthesia in the region of the trigeminal, by frequency of pulse, and laryngeal and respiratory crises, it is under the dependence of the progressive locomotor ataxia, but if these concomitant signs are wanting, the probabilities are strongly in favor of the diabetic origin of the glycosuria.

THE FUNCTIONAL IMPORTANCE OF THE COCHLEA.

Corradi (*Archiv. f. Ohrenheilkunde,* B. xxxiii., H. 1.) sums up his conclusions from an experimental study of this subject as follows: 1. That in the human labyrinth, other portions besides the cochlea exist where acoustic impressions can be received, is not as yet demonstrated. In guinea-pigs, after complete destruction of both cochleæ, total and permanent deafness is observed. 2. Partial injury to both corneæ does not necessarily lead to complete and permanent deafness; on the contrary, it sometimes occurs that, either immedialely after the operation or after a little time, the hearing power returns, owing to the remaining uninjured parts. In such cases temporary impairment of hearing must be attributed to shock, to loss of blood, or to the reactive inflammatory disturbance. The objection which may perhaps be raised that, because, after injury of both cochleæ, a certain degree of hearing may remain in many cases, other parts besides the cochlea should exist in thr labyrinth where sound impressions are perceived, C. considers unfounded, since in the first place, as his experiments show, all hearing is lost if, instead of partial, complete destruction of both cochleæ is caused; and secondly, because, in those cases where after injury hearing remains the degree is usually very variable. Were this due to other portions of the labyrinth and not to the uninjured remaining parts of cochleæ, it should exist not only in all cases of total or partial destruction, but its degree should always be the same. Thus it becomes easy to explain those cases where slight hearing has been observed after throwing off of the cochlea. 3. It is very probable that the perception of different tones, according to their pitch, takes place in different parts of the cochlea, and the deeper the tone the nearer to the apex is situated the part of Corti's organ by which it is perceived.

POST-PAROXYSMAL ALBUMINURIA IN EPILEPTICS.

Voisin and Peron (*Arch. de. Neur.*, May, 1892) infer from their researches that transient albuminuria follows the occurrence of a fit in about 50 per cent. of epileptics. To a certain extent the amount of albumin usually is augumented in proportion to the number of fits; it is greatest in those cases in which cyanosis and congestion of the face are most marked; and, as a rule, its maximum excretion takes place in the first two hours after the last fit. In the epileptic status the urine always becomes albuminous, consequently eclampsia and epilepsy cannot be differentiated by the presence or absence of albuminuria.—*Brit. Med. Jour.*

THE BLOOD-VESSELS OF NERVES

Quénu and Lejars (*Archives de Neurologie,* January, 1892) write that the principal characters of the arterial circulation of nerves are as follows:—

The superficial nerves are all accompanied in their entire length by an arteriole, which lies alongside, and prolongs itself by a series of archings. They thus form the principal guiding lines of the subcutaneous arterial system. Each nervous trunk receives its arteries from constant sources, and from this there result often physiological or morbid connections of great importance.

A nerve trunk never receives all its arteries from a single arterial trunk. All the conditions which, in the nerve-centres, prevent the direct and sudden afflux of blood, are to be found in the nerves.

The venous circulation presents the following characters:—The veins of superficial nerves all empty themselves into the deep veins: when they communicate with the superficial veins it is only by an anastamosis of small size, the deeper communication being always present. The veins of nerves forming part of an arterio-venous group empty themselves sometimes into a large neighboring vein, sometimes into the network of the vaso-vasorum which surround an artery, but mostly into the muscular veins.

PERIODS OF INFECTIOUSNESS.

Dr. Arthur Ransome, Owen's College, Manchester, sought to investigate the period of infectiousness of some of the infectious diseases by means of a circular letter sent to the English physicians. The results arrived at are that measles is infectious before the appearance of the eruption (in one case four days before.) The period of communicability extends to thirty-one days after the receipt of the infection. In four cases of scarlet fever the disease was communicated from twelve to twenty-four hours before the appearance of the rash, and in two cases it was communicated six weeks after the cessation of the disease. Mumps was shown to be infectious two weeks after the cessation of the fever, or three weeks altogether. Diphtheria is infectious from the receipt of the contagion until complete recovery, in ordinary cases about thirty-three days. The milder forms of small-pox are infectious five weeks; in the severe forms eight weeks.—*Zeit. f. Schulgesundheitspflege.*

SEPTICÆMIA SIMULATING TYPHOID.

A. Bruschettini (*Rif. Med.*, February 11th, 1892), during an extensive epidemic of typhoid fever, sought to isolate the B. typhosus from the splenic blood of a large number of patients. The blood was obtained by means of a perfectly sterile syringe, the puncture being made with strict antiseptic precautions; it was always taken either during the period of rising temperature or at the height of the disease, never during the period of defervescence. The blood thus obtained was mixed with an equal quantity of sterile bouillon, and placed in the incubator at 37° C. for twenty-four hours, after which it was examined. In eight cases the B. typhosus was found, six times in pure culture, twice accompanied by a streptococcus, but never with a staphyloccus. In seven other cases pure cultures were obtained of a small staphyloccus, which could be stained well by Gram's method. These proved in fact, to be staphylococcus pyogenes albus. In every case the diagnosis of typhoid had been made by the physician in charge from the clinical signs. There were, at first, moderate pyrexia, intestinal pains, headache; next, the spleen increased in volume. The fever was of an irregularly remittent type, seldom exceeding 40° C. There was generally constipation, never diarrhœa. The disease lasted from fifteen to twenty days, without the appearance of any signs of nervous depression which are common in typhoid. Taking the slight difference in clinical symptoms together with the results of bacteriological examination, which revealed the S. pyogenes albus even in the circulating blood, the author feels justified in regarding the above as cases of general infection with the S. pyogenes aureus, the microbe appearing to be present in a somewhat attenuated form. —*Brit. Med. Jour.*

SURGERY.

A NEW METHOD OF TENOTOMY.

The following are the steps of an operation which was performed in case of post-hemiplegic contracture of the flexors of the fingers, by W. W. Keen, of Philadelphia. An incision was made, beginning just above the pisiform bone, and extending three inches obliquely upwards, its upper end being over the tendon of the flexor carpi radialis. All the flexor tendons having been exposed, each tendon was first split along the middle for an extent of one inch and a quarter, and then, at the two ends of this incision, section of the opposite halves of the tendons was made; that is to say, the radial half of the tendon was divided at one end of the vertical slit, and the ulnar half at the other end. The long, loose ends of the divided tendon were then made to glide on each other in a vertical direction over a distance of about half an inch, and sewn together by two transverse sutures. The tendon was thus lengthened to the extent of three-quarters of an inch.—*Medical Age.*

OSSEOUS NEW-GROWTH IN THE MEMBRANA TYMPANI.

Dr. Haberman also found an osseous new-formation in the membrana tympani, in a woman thirty years old, who had died of phthisis. The left organ of hearing being examined it was found that the membrana tympani contained a large perforation, on the anterior edge of which there was a calcareous deposit 2-3 mm. thick and 4 mm. high. The end of the hammer-handle projected into the perforation, and the

tendon of the tensor tympani was bound to the anterior tympanic wall by fibrous tissue. Microscopic investigation of the middle ear showed a thickened mucous membrane, especially at the niches where the inner passes into the lower wall. In the membrana tympani at several points were found calcareous deposits, cartilage-cells, and, at one point, *true bone-cells,* with numerous delicate offshoots into the surrounding calcified tissue. No haversian canals and lamellæ were found.—*Amer. Jour. Med. Sci.*

THE TREATMENT OF ANCIENT LUXATION.

Thiery (*Gaz. des Hôpitaux, 1891,* No. 136) suggests that the expression "ancient" be replaced by "irreducible" luxation. In considering the measures to be employed in this class of cases he reaches the following conclusion: First. Under anæsthesia trial of manual reposition is to be made. Second. Forcible measures may be tried if manipulation fails. Third. Tenotomy is useless in this class of cases. Fourth. Arthrotomy is, as a rule, the operation of choice, particularly in luxations of the shoulder. Fifth. Resection, especially in combination with the artificial formation of acetabulum, is to be preferred for the hip-joint; in the shoulder-joint it may likewise be useful, but should be preceded by a trial of arthrotomy. Sixth. Osteotomy and osteoclasis have succeeded in a few cases of a desperate character; they are rarely indicated however. Seventh. At the present time there can be no justification for amputation, which was in former times resorted to upon occasion.

PERINEPHRITIC ABSCESS SECONDARY TO PLEURO-PULMONARY AFFECTIONS.

Tuffier (*Sem. Méd.*, May 11th, 1892) reports the following case. A woman, aged 34, suffering from broncho-pneumonia, with pleural effusion, suddenly developed symptoms of perinephritic abscess. A free incision in the loin gave issue to a considerable quantity of pus. On bacteriological examination this was found to contain only pneumococci. The the patient recovered well from the operation, only a small fistual being left in the loin, but she was suddenly seized with pneumonia of the side opposite to that first attacked, and died in a few days. On *post-mortem* examination it was found that the fat around the kidneys communicated freely with that around the pleura through a tiny track—a "costo-lumbar hiatus"—which exists in the normal state, and is constituted by the absence of some fibers of the diaphragm at one of its points of insertion into the aponeurosis of the quadratus lumborum. It was through this track, which is abundantly supplied with blood-vessels and lymphatics, that the infection spread from the thorax to the parts about the kidney.—*Brit. Med. Jour.*

CASE OF CONGENITAL OBLITERATION OF THE SMALL INTESTINE.

Thompson. (*Edinburgh Medical Journal*, March, 1892,) reports a case of a male child, who died on the eleventh day after birth, and who had had symptoms of intestinal obstruction, was found to be the subject of a remarkable anomaly. Just at the commencement of the jejunum the bowel terminated in a blind dilated end, and the mesentery ceased at the same point. A short distance beyond was an isolated loop of gut, blind at both ends, and two and a half inches beyond this the intestine became previous again.

A narrow fibrous band, which was probably due to old peritonitic adhesions, seemed to be the cause of the obliteration of the gut. When the mother of the child was two months pregnant, she had an ovarian cyst removed, but recovered without complications. Whether the fœtus suffered from peritonitis because the mother underwent ovariotomy, or whether the occurrence of peritonitis under such circumstances is a mere coincidence, is a matter for speculation. The original account of this case and the drawing which accompanies it are worth the reader's attention.

CATHETERISM OF THE BILIARY PASSAGES.

In the February number of the *Revue de Chirurgie*, Dr. Terrier and Dr. Dally conclude an exhaustive article on catheterism of the biliary ducts in conjunction with cholecystotomy or in the treatment

of the case after the performance of that operation. They think that this procedure is easier in pathological cases, especially those in which the passages are dilated in consequence of retention of bile, than it would be in experimental trials on the cadaver. In many cases it would be found difficult on account of curvatures of the cystic duct, or of the persistence of the valves, or of the cystic duct opening on the lateral wall of the gall-bladder. In some cases the difficulties will be insurmountable, while in others the exploration will be found quite easy. To formulate rules for this sort of catheterism is impossible; one can only be guided by one's anatomical knowledge. Forced catheterism, even with the finger placed under the liver in the abdomen, seems to be dangerous under all circumstances. Our information is as yet not sufficient to enable us to appreciate the value of *cathétérisme à demeure.* The instruments employed should always be sterilized.—*N. Y. Med. Jour.*

WHAT CAN WE EXPECT FROM THE SURGICAL TREATMENT OF EPILEPSY.

Dr. B. Sachs has a valuable communication in the *New York Med. Jour.* of Feb. 20, and the following are some of his conclusions: "1. In a given case of traumatic or organic lesion operate as early as possible to prevent the development of secondary sclerosis. 2. If you have not operated at the outset, the onset of epilepsy is a warning that secondary sclerosis has been established; by operation at this time you may avoid an increase of the trouble. 3. Excision of the diseased area is the only rational operation. If all other centres are not in an irritable condition the operation may be thoroughly successful. If we cannot easily cure epilepsy, we may improve the patient's condition by diminishing the number of attacks. Traumatic cases call for immediate surgical interference. As trepanation is not a very dangerous operation it would be better to do this than to have the slightest doubt. He thinks, under favorable conditions, and by the methods described in his article, the surgeon may be able to cure a few cases of epilepsy. He will be able to improve many, but surgeons and neurologists should in the future make an earnest effort to *prevent* epilepsy.

SPONTANEOUS CURE OF A SEVERE ABDOMINAL WOUND.

"Dr. Schildt mentions in *Duodecim,* a Finnish medical journal, a case, showing that, occasionally at least, a large wound into a serous cavity which looks hopeless enough may heal without treatment. He was called some years ago to a poor man supported by charity, who, in consequence of inflammation of the groin, had a large gaping wound of the abdominal wall, through which some six inches of the small intestine protruded, all covered with blood, added to which there was a discharge of fœtid matter. The man was sent to the hospital, where, however, he could not be admitted, as all the beds were full. He was therefore taken home again, and received no treatment whatever. Nevertheless, Dr. Schildt a short time ago happened to see him alive and well, the wound having healed spontaneously."—*Lancet.*

CYST OF THE MIDDLE TURBINATED BONE.

Charles H. Knight writes in the *Brooklyn Med. and Surg. Journal*: This condition affects the special sense of smell, the drainage of upper nasal fossæ, and may also be the cause of various reflex phenomena. The cysts are rarely large enough to interfere with the respiratory functions of the nose. The subjective symptoms are impairment of smell, persistent headache, neuralgia of fifth nerves, and some obstruction. On inspection the mucous membrane may appear atrophied, the tumor is firm and unyielding to touch, a considerable discharge of mucous into post-nares generally present. A case has been reported by Schaffer of cystic involvement of inferior turbinated, and one by Bayer of the superior turbinated; none have come under the author's observation.

This condition is frequently associated with myxomatous degeneration. Females are more often affected than males, and most of the patients have been past middle life. No case occuring during childhood has been reported.

This condition must be differentiated from osteoma, myxoma and mucocele of the ethmoid cells.

A cross-section of a cyst presents the following microscopic appearances: On outer surface a layer of pavement epithelium, beneath a strata of connective tissue,

moderately vascular. Under this a layer of bone of varying thickness, then a lining of loose connective tissue, and covering the inside of the cyst a row of ciliated epithelium. The lesion causing this condition is probably an osteophytic periostitis, followed by a hypertrophic rhinitis. The bone of middle turbinate curls upon itself until it reaches and adheres to its own base. The external layer of mucous membrane may hypertrophy or atrophy from pressure. The glands on internal surface secrete until cyst cavity is filled to distension, when the atrophic process is initiated. The cyst contents may become purulent. The treatment is entirely surgical, consisting of removal of mass by means of cold wire snare. In case it is impossible to ensnare the growth it may be removed by means of the cutting forceps and scissors. To examine cyst contents, hypodermic puncture is necessary, as the cyst walls are always broken during the removal of the bone. The hæmorrhage during the operation is generally insignificant.

The indications of surgical interference are as follows:

1. Obstruction of nasal respiration.
2. Prevention of nasal drainage.
3. Reflex neuroses.
4. Anosmia.
5. Impaired quality of voice.

RADICAL TREATMENT OF DACRYOCYSTITIS.

Guaita (*Centralbl. für prakt. Augenheilk.*, No. 1) recommends curetting the lachrymal canal and the introduction of a decalcified bone tube into the duct previously divided, for the relief of dacryocystitis. The tubes are prepared from the bones of the hind-legs of large turtles; the bones are treated with dilute hydrochloric acid, and the medullary cavity cleansed; the tubes are kept in absolute alcohol and a solution of mercuric chloride, 1: 500. They should average about an inch in length, and from a tenth to an eighth of an inch in diameter. After the lachrymal canal is opened and curetted, it is cleansed with gauze saturated with a solution of mercuric chloride, 1: 2000; the tube is introduced, and the wound is closed with one or two sutures. A compress wet with a cold solution of mercuric chloride is afterward applied. Unless severe inflammatory symptoms be present, a cure can be expected in from four to six days.—*Wiener medizin. Presse*, 1892, No 15, p. 594.—*News.*

CATHETERIZATION OF THE BILIARY DUCTS.

After a lengthy discussion of the normal anatomical structure and the pathological changes produced in the biliary ducts and their relations to catheterism, Terrier and Dally (*Revue de Chirurg.*, 12e année, No. 2) come to the following conclusions: 1. In general the catheterization is easier under pathological conditions, especially when the ducts are dilated by a stoppage in the valves or at the distal end of the cystic canal. 2. Nevertheless, in many cases, owing to the curvatures in the canal, the persistence of the valves or the opening of the duct upon the lateral wall of the sac, the catheterism is difficult. 3. Often the difficulty is insurmountable, often there is none. 4. Rules for the passage of the catheter are impossible, owing to the variations in the anatomical relations. The only way is to attempt the catheterism with a clear idea of the normal relations for a guide. 5. Forced catheterism, even with a finger externally to direct the instrument, is difficult and in all cases dangerous. 6. The treatment is not well enough understood as yet for its value to be appreciated. 7. The instruments to be used are olive-pointed bougies and Bénique's catheters, with or without stylets. Liver catheters are of rare use. 8. In all these operations strict antisepsis must be observed.—*Amer. Jour. Med. Sci.*

THE UNION OF DIVIDED TENDONS

Busse (*Deut. Zeit. f. Klinische d'Orthopédie*, tome v., 6 année, No. 5) finds, as the result of repeated experiments, that in the cases of tenotomy, immediate complete union is never obtained. Even when the ends of the divided tendons are sutured, exact apposition never persists. An extravasation of blood filling up the space between the divided ends of the tendon is utterly useless; in fact, it retards cicatrization, which does not begin until the clot is absorbed. Union is very much more rapid when the wound is

rendered bloodless, and when no clot is present. The peritendinous and interfascicular tissues furnish by cellular proliferation the splint which unites the divided tendon. This splint requires many months to become identical in structure with the tendon.—*Therapeutic Gazette.*

OBSTETRICS.

ABUSE OF ERGOT IN THE FIRST STAGE OF LABOR.

Chaleix (*Nouv. Arch. d'Obstèt, et de Gynèc.*, April, 1892, Supplement, page 154) relates a case where a midwife gave ergot freely in the first stage of labor. The cervix was so much affected that it felt as though made of ivory. As the cervix was the part most affected, Barnes's bag was used, the instrument known by the name of Champetier de Ribes, which distends the whole uterine cavity, not being indicated. Chaleix succeeded in turning and delivering the child.—*Brit. Med. Jour.*

STERILITY IN THE MARRIED.

Seeligmann (*Berliner klinische Wochenschrift*, *Annals of Gynæcology*, May, 1892), is most favorably impressed with the effects of massage and electricity in many cases of sterility due to faulty conditions in the female generative organs. These measures of treatment are especially beneficial in cases of chronic disease of the appendages, rising after parturition, with resulting sterility. The size of the ovary has been known to diminish, its functional activity to return, and a distorted and adherent tube has become loosened, and straightened and its canal patulous. In applying galvanism to the uterine cavity, the author always uses the negative intra-uterine electrode, as it possesses only a weak cauterizing action and produces an alkaline reaction of the uterine secretion, which is favorable to the prolonged life and activity of the spermatozoa.—*Univ. Med. Mag.*

CÆSAREAN SECTION IN A CASE OF ABNORMALLY LONG CERVIX.

Aalsmeer, of Surinam (*Centralbl. f. Gynäk.*, No. 1, 1892), is the first who has ever performed Cæsarean section in Surinam. The patient was a negress, aged 22. Her first labor was finished by perforation. She was admitted into hospital during her second labor, after the pains had continued for a whole day. It was found that the cervix was 6 ⅔ inches long, the vaginal portion alone measuring 3½ inches. The tissues were soft, and the canal only admitted the finger with difficulty. The pelvis was flat and uniformly contracted; the conjugata inclinata measured 3 ⅗ inches. Conservative Cæsarean section was performed. Hæmorrhage was trifling; the temporary ligature was not needed. The patient recovered, and the child survived.—*Brit. Med. Jour.*

PEDIATRICS.

HOW TO RAISE SYPHILITIC INFANTS.

Dr. Nicolle (*L'Union Médicale*, February 2, 1892), in his work on the nursery of the hospital of the *Infants Assistes* recommends that an infant with hereditary syphilis should

1. Be nursed by its mother, or if this is not possible by a nurse who is syphilitic.

2. If neither mother nor nurse can be secured that it is well to let the infant take the milk direct from the teat of an ass, but only for the first few months.

3. This must be replaced later on by cow's milk. The arrest of development in the infant indicates the time when this change should be made.

4. In the impossibility of securing ass's milk we must resort to diluted cow's milk, sweetened and boiled. It is always a defective alimentation.

5. Whatever food is adopted it must be continued much longer than in the case of a healthy child. It seems to the author there would be an advantage in giving goat's milk taken from the udder of the animal from the age of six or eight months up to sixteen months longer.

6. Treatment by Van Swieten's fluid from fifteen to fifty drops per day according to the age, strength intensity of the manifestations, etc., is advised. Occasionally the dose may be increased but should never exceed five grains.

7. Most minute attention should be paid to hygienic measures, baths, change of air, etc.

SALICYLATE OF BISMUTH IN INFANTILE DIARRHŒAS.

Mikhnevitch (*Med. Obozreniĕ*, No. 6, 1892), having tried the salicylate of bismuth in 50 cases of diarrhœa in infants under two years of age, reports that, of the number, only 2 died (a boy of 8 months with pelvic suppuration consecutive to intractable colitis; and an infant of 5 months, born prematurely and exceedingly sickly since its birth). The following formula is recommended: ℞ bismuthi salicylici, gr. xxiv; gummi arabici, ℥j; sacch. albi, ℥jss; terendo adde aq. dest., ℥ij; fiat lac, tum adde aq. dest, ℥iv. M. D. S. The bottle to be kept in cold water or ice, and to be shaken well before use. One or two teaspoonfuls to be given from three to six times daily. Each teaspoonful of the mixture contains about ½ grain of the salicylate, which constitutes a normal dose (three or four times daily) for an infant of from 6 to 8 months old. In cases of offensive diarrhœa the administration should be preceded by a dose of castor oil. The bismuth salt should be given regularly until the diarrhœa has completely subsided. It must be kept in mind, however, that in large doses the remedy is apt to induce perspiration with consecutive weakness (especially in exhausted children), hence a corresponding reduction of the dose may become necessary. In acute cases the remedy is useless, but in all of a week's standing or longer its effects are said to be excellent.—*Brit. Med. Jour.*

HYGIENE.

IMMUNITY AND THE TREATMENT OF RABIES BY THE BLOOD SERUM OF PROTECTED ANIMALS.

Professor Guido Tizzoni and Dr. R. Schwarz, in a preliminary communication (*Riforma Med.*, August 22nd, 1891) give an outline of the results obtained by them during the past year in a series of experiments undertaken for the purpose of determining the following questions: (1) What is the active principle which confers immunity on vaccinated animals against rabies, and can the serum of these animals transmit immunity to others not so vaccinated? (2) Given that the serum can transmit immunity, what is the nature of the substance possessing this power, and can it be obtained and preserved in solid form? (3) Can the serum of vaccinated animals, besides conferring immunity cure animals already infected if given during the incubation period? They made most of their experiments on rabbits, which are much more easily rendered rabid than other animals. For vaccinating these and also the dogs used, they employed the method of Pasteur and Protopopoff. The vaccine employed was a virus obtained from a rabid dog, and passed once through a rabbit. Their results may be summed up as follows: (1) The serum of vaccinated rabbits, even after a brief contact *in vitro*, destroys the activity of a virus of rabies, even if this has been first strengthened by two or three passages through rabbits. This is proved by making a pulp of the medulla of a rabid animal, mixing it with the serum to be tested, and keeping the mixture in a cool place for a few hours, using it afterwards for subdural inoculations. (2) This serum retains its antirabic power for several days if kept at a low temperature. Injected into the jugular of unprotected animals (about 5c.c.) it confers immunity not only against infection by subcutaneous inoculation, but also against that by intravenous or subdural injection. (3) The serum of vaccinated dogs has a much less powerful action. It will not *in vitro* annul the action of a virus reinforced beyond the first passage through a rabbit; injections also of 4 c. c. and even double that quantity are not constantly sufficient to secure immunity against infection by a "direct" virus introduced either into the sciatic or under the dura mater. (4) The serum of rabbits rendered immune by serum from vaccinated animals does not confer immunity on a third generation of rabbits, even against intrasciatic injections of a weak virus. It is also without effect on a virus exposed to its action *invitro*. The immunity obtained by the injections of serum appears therefore to be less than that conferred by vaccination. (5) Not only the degree but also the duration of the immunity conferred by the serum of vaccinated rabbits is less than that obtained by direct vaccination. Serum-protected animals are found to be again susceptible after about six weeks, while vaccinated animals are protected even after ten weeks. (6) The active substance contained in the serum appears absolutely non-dialysable. (7) This substance is precipitated by alcohol, but in the precipitation it loses some of

its activity. The same result takes place if one precipitates by alcohol the globulin obtained by saturation with magnesium sulphate from the serum of vaccinated animals. (8) Glycerine extracts the active principle from the alcoholic precipitate. (9) If the globulin be separated from the serum by means of magnesium sulphate collected on a filter, dialysed free from salts, and redissolved in salt solution, it will be fonnd that this solution has the power of destroying rabic virus, whereas the filtrate has not. This is similar to what happens in the case of tetanus, and shows that the active principle is either a globulin or is precipitated along with a globulin. (10) This substance is not identical with that which confers immunity against the products of the tetanus bacillus. (11) With regard to the cure of rabies by means of the serum from vaccinated animals, the authors have one decisive experiment. In this the injection of 5c. c. of serum from a highly-vaccinated rabbit into the jugular saved another rabbit inoculated twenty-five hours before in the sciatic with a mild virus. (12) The serum from vaccinated dogs exerts no such favorable action. This is the first time that it has been found possible to save a rabbit after injection with the virus of rabies. Vaccination has always failed in the case of this animal. The results stand in perfect harmony with those already known with regard to tetanus, and would seem to show that immunity against rabies is not a special form, differing from that against other infections.—*Brit. Med. Jour.*

THE EMPLOYMENT OF UNBURNT LIME FOR PURIFYING WATER.

Professor Szpilman, of Lvow, successfully employed unburnt lime for removing from the water *crenothrix* and *cladothrix* which, as it is known, develop in springs, wells, basins, water pipes, etc. These micro-organisms, forming greenish-brown tufts, which swim on the surface of the water or collect on the bottom, render it unfit for drinking purposes, although they are in themselves harmless to man. Sometimes they clog or stop up the water-pipes. The author convinced himself that unburnt lime, in the quantity of 0.5 to 2 kilos of powder to 100 litres of water, or 20 to 40 per cent. of lime-water, entirely destroys the micro-organisms in twenty-four hours. In Lvow, two springs were purified by this means.—*Zdrowie*, August, 1891.

MEDICAL CHEMISTRY.

NATURE OF SOLUTION.

Professor Wanklyn has published several papers bearing on the subject of solution, and giving the conclusions derived from experiments made by him and his colleagues during a number of years. He announces a law which is applicable to gases as well as liquids. It is to the effect that heterogeneity is without influence on volume; that is, that the volume of a mixture is equal to the sum of the volumes of its constituents separately measured. This, of course, only applies in the absence of chemical combination, and it may be argued that when this law does not hold good the case is one of chemical rather than simple solution.

In the instance of a mixture of alcohol and water, there is a considerable contraction in volume, and much heat is evolved. This indicates chemical union, and this view is further strengthened by the fact that it is impossible, by distillation alone, to remove from such a mixture the last eight per cent. of water.

In the case of sugar and water the results are different. Solutions of sugar occupy almost exactly the same volume as the sugar and water would if measured separately. This was found to be strictly true with solutions up to 105 grammes of sugar in the litre. This showed the specific gravity of fluid sugar to be 1.635. In solutions stronger than this the density of the sugar is a little lower, viz., gravity of solid sugar. The fact is that in passing from the liquid to the solid state there is a a slight expansion, about one-fiftieth. In thick, viscid syrup there is present the slightly expanded sugar, but, in the more fluid solutions the fluid sugar is found, having the specific gravity above indicated.

Saline solutions in some respects resemble those of sugar, but are dissimilar as to contraction, the latter being very considerable. The view taken of such is "that they are mixtures of fluid hydrates with water, and that the fluid hydrate simply diffuses into the water, or mixes with the water, without changes of volume of any kind.—*Can. Pharm. Jour.*

THE CLINICAL EXAMINATION OF BREAST-MILK.

At the recent meeting of the American Pediatric Society, Holt detailed a simple method of examining breast-milk for clinical purposes. There are two ingredients in milk that are nearly constant in their proportions: milk-sugar and the inorganic salts. Two others vary widely: fat and the proteids. From a knowledge of the specific gravity and the amount of fat, it thus becomes possible to form an approximate idea respecting the proteids. There were found to be in breast-milk a pretty constant relation between the amount of cream rising upon a given specimen in twenty-four hours and the amount of fat. The ratio was approximately two to one.

An apparatus was shown for taking the specific gravity of a small quantity of milk, and cylindrical tubes graduated in one hundred parts, from which the amount of cream could be read off at the end of twenty-four hours. The clinical significance of these data was shown by the following table, drawn from observations upon upward of three hundred specimens of breast-milk from eighty different women.

Attention was called to the fact that an estimate of the quantity must be made by other means. The specimen for examination should be taken from the middle of the nursing.

HUMAN MILK.

	Specific gravity 70° F.	Cream—24 hours.	Proteids.
Normal average.	1.031	8 per cent.	Normal.
Healthy variations	1.023–1.029	9 per ct. to 12 per ct.	Normal (rich milk).
Healthy variations	1.032–1.033	5 per ct. to 6 per ct.	Normal (fair milk).
Unhealthy variations	Below 1.028.	High (above 10 per ct.)	Normal or slightly below.
Unhealthy variations	" "	Normal (5 per ct. to 10 per ct.)	Low.
Unhealthy variations	" "	Low (below 5 per ct.)	Very low (very poor milk.)
Unhealthy variations	Above 1.033	High	Very high (very rich milk).
Unhealthy variations	" "	Normal	High.
Unhealthy variations	" "	Low	Normal (or nearly so).

NEWS AND MISCELLANY.

ARTIFICIAL CHOREA.

M. Chares Richet, the well-known French physiologist, has succeeded in inducing chorea in a dog by injecting the blood of an animal suffering from this motory disturbance. The injections were followed by general atrophy, by trophic lesions of the skin in various parts of the body, and by rhythmical convulsions of the limbs, continuing during sleep and yielding only to large doses of chloral. It cannot truthfully be said that the experiment adds much to our knowledge of the ætiology or even the pathology of this affection. Apart from the fact that a single experiment proves nothing, there are too many alternative explanations of the phenomena observed.—*Med. Press.*

THE ABUSE OF COCAINE.

Mr. Conolly Norman, of Dublin, contributes a paper on this subject to the last number of the *Journal of Mental Science.* He says that undoubtedly much harm has resulted from a recent tendency to use cocaine to break off the morphia habit, and from the mistaken notion that this drug can be employed safely and advantageously for this purpose. Cocaine, the author remarks, is more insidious than morphia; it fastens upon its victim more readily, and its hold is at least as tight. The special dangers of cocaine are said to be three: (1) That it is treacherous; (2) that it early produces breakdown, both in the moral and intellectual spheres; and (3) that it is intensely toxic, bringing about destructive tissue change after a comparatively short period of abuse. In the last respect it differs from alcohol and morphia, which may be long indulged in, in considerable quantities, without giving rise to serious structural change. In chronic cocaine poisoning, on the other hand, marasmus appears early and develops with extreme rapidity, convulsions are not uncommon, and chronic poisoning in animals produces, as Zanchevski has shown, degeneration in the cells of the medulla and spinal cord, and also in the nerve cells of the heart ganglia, and in the liver cells. The great danger of cocaine lies in the fact that it is the most agreeable and alluring of all narcotics. It causes no mental confusion, only a little more talkativeness than usual, the narcotic effects are not overwhelming, and there is no headache or nausea, and the pleasant effects are produced with a comparatively small dose. But toxic symptoms are rapidly developed, and within three months of the commence-

ment of the habit there may be marked indications of degeneration, loss of memory, hallucinations, and suspicions. Dr. Norman has seen three cases of abuse of cocaine. In one the drug was given as a substitute for morphia, in the second it was first given for a painful affection of ths nose, and in the third the patient was in search of a new stimulant. The symptoms in the first case were hallucinations, sexual excitement, and loss of sense of the passage of time. The second patient was elderly, and after six months' use of cocaine, he fell into a state of mental hebetude, with loss of memory and broken, irregular sleep. He was also tormented with sexual excitement. In the third case, a young man, the memory was failing, he was furtive and shifty in manner, and could not speak the truth. He also had visual hallucinations, and at first sexual desire was increased, but latterly diminished. These cases seem to furnish fair examples of the usual condition produced—a condition sufficiently serious to put medical men on their guard against prescribing too freely a drug so insidious and so dangerous.—*Lancet.*

A STRANGE MEDICO-LEGAL CASE.

Dr. F. Semeleder writes in the *Medical Record*: One evening in May, 1891, a woman, belonging to the middle class, presented herself at a police station of this city, crying and in great distress, asking for medical assistance, because her husband was very sick and had probably poisoned himself. The employee and surgeon went to the patient's house, found him almost dying; signs of disorder in the house and room, as is natural in case of such an accident. On the table there was a small vial labelled morphia. The sick man was taken to the municipal hospital of San Pablo, where he died the next morning, without having once recovered consciousness even for a minute. The widow and family were extremely anxious to have the corpse delivered to them to take home. They wished to wash and dress it and have a funeral. However, as there were some strange features about the case, they were denied their petition, and a post-mortem ordered, which furnished the following curious data:

No external lesion was found. The nostrils and mouth showed signs of a bloody discharge and the nasal cavity was full of bloody cotton. After opening the skull no signs of congestion of the brain were noticed; after taking out the brain, at the base of the anterior lobes a small portion was reduced to a pulp. On the base of the skull the cribriform plate of ethmoid bone showed fractures communicating with the nasal cavity and corresponding to the brain lesions before mentioned. These fractures were probably caused by some pointed instrument (afterward it was known to have been an iron hook) introduced with great force and turned around in various directions. A little further back, and in the right fossa of the cerebellum, between the dura mater and bone, there was an extravasation of coagulated blood: after removing this blood a fracture was discovered at the base of the skull, which parted from the occipital foramen and extended into the mentioned fossa.

The mouth, nasal, and pharyngeal cavities were full of blood-clots; above the soft palate, in the fundus of the pharnyx, a small wound made with a pointed instrument and only interesting the mucous membrane. The sixth, seventh, eighth and ninth ribs on both sides were fractured, near the insertion of the cartilages and on the pleura were corresponding ecchymoses, like those occurring in cases of sudden death.

It is evident that the lesion, partial destruction of the brain, was the cause of death in this case. The murderer, whoever it was, must be possessed of certain anatomical knowledge and of a great amount of shrewdness. No further particulars are known, as the case has not yet been brought to a trial.

PRIZE FOR ESSAY ON TUBERCULOSIS.

The Congress for the Study of Tuberculosis announces a prize of three thousand francs for the best essay on "The Means of Diagnosticating Latent Tuberculosis before its appearance or after its Cure." The essay must be written in French and sent to Dr. L. H. Petit, 76 Rue de Seine, Paris, before April 1, 1893. Each memoir should be accompanied with a sealed envelope containing the author's name and address.

THE
MEDICAL AND SURGICAL REPORTER.

No. 1855. PHILADELPHIA, SEPTEMBER 17, 1892. Vol. LXVII—No. 12.

Clinical Report.

PRESBYTERIAN HOSPITAL, TENG CHON FU, CHINA.

DR. ROBERT COLTMAN, JR.

Case 1. Man, age 30, soldier. Says he has had a pain in his left leg running from his toes up into the groin. Says also he has several lumps in the groin which antedate the pain and he believes causes it. On removing his trousers we find a red line running from several indurated glands in the groin to an ulcer situated between the second and third toes. There is an offensive secretion arising from this ulcer.

His penis is swollen and shows signs of recent inflammation and he acknowledges having had a hard chancre which has caused this infiltration but he says all active inflammation ceased six months ago. The ulcer between the toes appears to be a condyloma though this is not a frequent situation for it. We have then a phlebitis caused by poison absorbed at the site of a condyloma between the toes. I do not attribute the phlebitis to the condylomatous ulcer but as the man is exceedingly dirty and wears no stockings, I think the irritation of the bare shoes or filth has caused the inflammation.

I shall have him wash his feet and apply some benzoated oxide of zinc ointment between the toes and give him internally a half ounce of Epsom's salt to be followed after eating by 20 drops tinct. ferri chlor. for several days. The course of the vein we will paint with tinct. iodine twice daily. Specific treatment we will defer until after this local disease has yielded to our treatment.

Case. 2.—One glance at this man tells you his disease. It is leprosy. He is but 30 years of age and yet looks fifty. He says he has had the disease about seven years and that the first he noticed of it was a numbness, followed by entire loss of sensation in a few months, in the left foot. His father is living and 63 years old and healthy. Mother also alive and well, age 56. Only has one sister and she is healthy. In a village a mile away are two brothers who are lepers, but he has had no communication with them. He has lost his eyebrows and most of his hair which with the copper-colored hypertrophic ridges in the forehead and cheeks disfigure him greatly and make him look much older than he is. What is of more moment to him, however, than disfiguraation is the loss of several joints from the fingers of both hands and the contraction of the flexor tendons so that he with difficulty extends his stumps of fingers to grasp anything. You notice he can scarcely place his phial on the counter. His toes have also lost some joints but the tendons have not contracted. Sensation abolished to the knee, deficient from there to the abdomen but good over abdomen and chest. Deficient but not abolished on face, deficient also in both arms, particularly bad in left. He has no open ulcers at present so we will only treat the general condition. We will repeat what he has been taking and what he says makes him feel better, though as he has no pain whatever I think is imagination, namely, twenty drop doses of syr. ferri iod., three times daily. This man owns to having had syphilis at 23 or just about the time of the first development of numbness. Now, although I don't believe all lepers syphilitic, I do believe that syphilis prepares the body for the reception of the leprous germ and other things being equal I believe a non-syphilitic person able to re-

sist contagion much better than a subject of syphilis.

Case 3.—This little girl is eight years old and her mother says she is constantly crying with pain in the stomach. There is no set time for the pain to come on but eating food relieves it usually for some time. Appetite is capricious and nausea frequent. She vomited up a long round worm last night which the mother declares was a foot long. Her tongue is a typical worm tongue being coated with a thin white fur through which especially at the sides the red papillæ arrange themselves in rows more or less even. We shall give her three grains each of santonine and calomel rubbed up with ten grains of sugar of milk and divided into three powders. One powder to be taken each night and morning on an empty stomach and after the three have been taken, followed with a dessertspoonful of castor oil. We can safely expect this to effectually remove all symptoms.

Case 4.—This man, age forty, says he is always filled up with wind. Worse immediately after eating but even when hungry he feels full.

On palpation we find no evidence of retained fæces but evidently he has considerable wind in the bowels. His diet is largely cabbage and bread with raw onions or radishes. He suffers considerable pain at times but has never vomited. Is not at all sensitive on pressure. Is chronically constipated. A change of diet would be a good thing but that to any marked degree is impossible owing to his poverty. We will tell him however to have his cabbage well cooked and to eat his bread when a day old. There is evident lack of biliary secretion and perhaps inactivity of all the glands concerned in the process of digestion. I shall give him the following pill to be taken just before meals:

℞ Pulv. podophyllin.....gr. j.
Acid carbolic.....gr. viij.
Gum assafœtida.....gr. xlviii.
Ext. taraxicum.....q. s. ft. pill xvi.

This combination I usually find successful in this class of cases but occasionally arsenic in Fowler's solution gtt ij before meals will be better.

Case 5.—This boy, eighteen years old, comes back to us after an absence of two years. Two years ago he was in the hospital with pleurisy of the left side, and after the effusion subsided he was left with an atelectasis of the left lung so that his right lung alone aerated the blood. I kept him under observation at that time for over two months and although he had no fever after the effusion subsided yet his pulse continued uniformly at 120 beats per minute. Then I sent him to his home in the country forbidding his attending school for a year. I have not seen him since. Now to-day what do we find to be his condition. He has grown some taller and much stouter than he was when I last saw him and his chest is not retracted to the degree it was then, though he has a decided stooping of the left shoulder.

On auscultation I find great improvement the upper two thirds of this formerly useless lung is now receiving and expelling air with each inspiration. The lower third is still flat on percussion, there is no vesicular murmur to be heard over it, and it is apparently glued up so tight that it will not expand any more. Nature has by pure air and exercise on a farm, given this boy a fairly useful lung, whereas if he had remained in the city and at school he would probably have gone into consumption. He now comes back to school, for which I am sorry. Boys in his condition who have the elementary education he has should remain in the country and by judicious reading acquire all the education necessary to an outdoor life. If cooped up with many others bad air will have its effect on him and his health will break down under it. As he has merely come to be examined we will report him as much better and advise his return to the country instead of going to school as he desires.

EXALGINE.

From a study of the analgesic properties of exalgine made by Dr. Dèsirè, at the Hôpital Lariboisière, the conclusion was drawn that, aside from any antithermic action, the product is an admirable specific against pain. It was employed in a great variety of apyretical affections with uniform success. The dose of twenty-five centigrammes, or about four grains, was found sufficient for most cases, but it can be pushed to double or treble this quantity, though as much as a grain is scarcely ever necessary. If medicine rarely cures, it should at least always console, and sometimes relieve, and with exalgine the author thinks great relief can often be given.

Communications.

QUALITATIVE TESTS FOR SUGAR IN THE URINE.*

By J. D. RIKER, B. S., M. D.,
PONTIAC, MICH.

It is known by those who have had considerble experience in testing the urine for sugar, that nearly every test is more or less unreliable. In view of this fact we have made a careful study of all the more important sugar tests, applying them to a large number of specimens of normal and abnormal urine and to standard sugar solutions, as well as to the isolated organic constituents of urine in health and disease in order to find if possible the substances that interfere with the more common tests and the means by which they may be avoided so that the presence or absence of sugar may be known beyond the question of a doubt. (For formulæ of the tests referred to in this paper, see the end of this article, also the formulæ for certain tests that have appeared from time to time in journals as reliable but which are in no way superior or even equal to some of the common tests herein reviewed.)

THE COPPER REDUCTION TESTS.

The copper sulphate solutions in general use are (1) Trommer's, (2) Fehling's, and (3) Pavy's. While we have many modifications of these, only the most important will be touched upon.

1. Trommer's Test. To two or three c. c. of urine in a test tube, add one or two c. c. of caustic soda or potash, then drop by drop a solution of cupric sulphate 1:10, until the precipitate formed appears to have dissolved completely; heat the upper portion of the mixture and if the urine contains sugar a yellowish red precipitate is formed in the heated layer (before reaching the boiling point.)

2. Fehling's Test. Pour Fehling's solution, to a depth of three fourths of an inch, in test tube; boil and add a few drops of the urine. In a few seconds the mixture will become suddenly yellow if the urine be diabetic.

3. Schmiedeberg's Solution is applied the same as Fehling's.

4. Pavy's Ammoniated Copper solution works nicely in making quantitative estimations of glucose in water solutions, but cannot be applied to urine with any satisfactory results, as shown by testing a large number of normal urines, every one of which gave reactions for sugar, the amount of urine used in each test not exceeding the amount of the test solution.

The precautions to be observed in the use of the copper reduction tests are as follows: In the application of Trommer's test to the urine, notice first that the disappearance of the blue color of the copper sulphate solution is no proof of the presence of sugar. The blue color is caused to disappear by the action of the alkali upon the organic matter present; not only must the blue color disappear but there must be a distinct precipitate of the sub-oxide of copper (4). Now this precipitate is to be recognized by its color, as on the addition of caustic soda or potash the phosphates will be thrown down as a dirty white precipitate, which is to be distingnished from the red or yellow sub-oxide of copper thrown down by sugar (4). Again, continued boiling will in fifty per cent. of normal urines reduce the copper sulphate. Sometimes the reaction fails unless the urine be diluted before testing. (Kulz). The power of a urine to dissolve the cupric oxide does not necessarily imply the presence of sugar, as ammoniacal or albuminous urines may do the same. (V. Jaksch.) In the application of Fehling's test and its modifications observe the following rules:

1. Boil your Fehling's solution to see that heat alone will not cause a reduction.

2. Never add more urine than you use of the reagent.

3. The Fehling should never be added to the boiling urine; but to the boiling Fehling add your urine drop by drop, five or six drops being sufficient in the majority of diabetic urines to completely reduce the copper.

4. Never boil longer than thirty seconds after adding the urine.

5. If there be albumin present in the urine it must be removed. If the urine be acid and contain but little albumin, the albumin is removed by heat and filtration. If the urine be not acid it should be rendered so by the addition of acetic acid, avoiding an excess, then heated and filtered. The filtrate should then be rendered alkaline
